Plasma binding of vitamin B₆ compounds

PYRIDOXINE, the major dietary form of vitamin B₆, is rapidly converted in the body to pyridoxal phosphate (pyridoxal-P), the coenzyme form. Pyridoxine has been shown to be phosphorylated in liver and brain homogenates¹ and in red cells², and is subsequently oxidised to pyridoxal-P. In the red cell pyridoxal-P is dephosphorylated, and pyridoxal is the form that is then released into plasma². But the endogenous form of B₆ found in plasma is mainly pyridoxal-P. This paper reports our findings on the ability of plasma proteins to bind these two circulating forms—pyridoxal and pyridoxal-P, and their dietary precursor, pyridoxine. We found that there were marked differences in the extent to which each B₆ compound was bound. These findings can be interpreted to explain part of the mechanism which regulates the passage of B₆ compounds into and out of the red cell.

Heparinised or clotted blood samples were obtained from normal human subjects. When heparinised plasma was compared with serum, no differences in the elution pattern of vitamin B₆ compounds were observed. The proteins were fractionated by gel filtration at 4° C on a 2.2×90 cm acrylic column (Wright Scientific, Kenley, Surrey, UK) of Sephadex G200, eluted with 0.05 M phosphate buffer pH 7.4 containing 0.154 M NaCl. The flow rate was 12 ml h⁻¹ and 130×4 ml fractions were collected. The vitamin B₆ compounds used were crystalline pyridoxal and pyridoxal-P (Sigma) and ³H-labelled pyridoxine (Radiochemical Centre) with specific activity adjusted to 62 mCi mmol⁻¹ by the addition of unlabelled pyridoxine (Sigma). Pyridoxal, and pyridoxal-P after acid hydrolysis to pyridoxal, were measured by microbiological assay using *Lactobacillus casei*³. ³H-pyridoxal, derived from red cell conversion of ³H-pyridoxine, was distinguished from ³H-pyridoxine by *L. casei* activity of the former². Protein was measured by absorbancy at 280 nm.

The gel filtration pattern of the vitamin B₆ compounds in the absence of plasma was first established (see Fig. 1). In these experiments each compound (1,000 ng in 2 ml saline) was eluted separately through the column and fractions were selected for microbiological assay or ³H-counting. In each case the vitamin B₆ eluted in a single symmetrical peak with maximum concentration in fractions 106-108 (free position).

Experiments were then carried out in which 1,000 ng (0.02 ml) of each vitamin B₆ compound was incubated separately with plasma (2 ml) for 30 min at 37° C and then subjected to gel filtration. Fractions were selected for microbiological assay, ³H-counting and protein measurement. Each compound eluted differently as shown by the representative set of experiments illustrated in Fig. 1. Pyridoxine added to plasma eluted in exactly the same fractions as pyridoxine in saline, demonstrating an absence

of binding to protein (Fig. 1a). In contrast, pyridoxal-P eluted almost entirely with the third protein peak (Fig. 1b) which consisted mainly of albumin, transferrin and 3.5S α -glycoprotein¹. In the case of pyridoxal, a significant proportion was associated with the same protein peak, but most eluted in the free position (Fig. 1c). Exactly the same pattern of elution was demonstrated for pyridoxal contained in samples of plasma separated after whole blood had been incubated with 500 ng ml⁻¹ of ³H-pyridoxine (Fig. 2) or pyridoxal.

The binding of the different B₆ compounds to plasma protein will be discussed in relation to our earlier findings on vitamin B₆ metabolism in blood². These demonstrated that the uptake of pyridoxine by red cells, after an initial rapid phase, slowly proceeded to completion as conversion of pyridoxine to its active forms took place in the red cells. This uptake and conversion were independent of the presence of plasma since the kinetics were identical whether the red cells were suspended in plasma or saline. It is therefore not surprising that we found no binding of pyridoxine by plasma proteins (Fig. 1a).

In contrast, pyridoxal-P is totally bound to protein (Fig. 1b) and pyridoxal seems to be partially bound (Figs 1c and 2). In relating these findings to our earlier work it is valuable to consider some observations made by Dempsey and Christensen³ in a study of B₆ binding to purified bovine serum albumin. These authors came to the conclusion that albumin has two specific binding sites for pyridoxal-P with relatively high association constants, but that in addition, both pyridoxal-P and pyridoxal bind less strongly to additional sites. If this also applies to human albumin in plasma, and we found that pyridoxal-P was completely eluted in the albumin-containing peak (Fig. 1b), then the strong

binding of pyridoxal-P by albumin would account for the inability of pyridoxal-P to enter the red cell from plasma, in contrast to its substantial uptake by red cells suspended in saline².

In view of the findings of Dempsey and Christensen³ and of the elution pattern we observed (Figs 1c and 2), it is probable that the pyridoxal-binding protein of human plasma is also albumin. Although only partial binding of pyridoxal is apparent from our results, the poor separation between bound and free peaks (Figs 1c and 2) is suggestive of dissociation of pyridoxal from albumin during gel filtration, in accordance with their weak binding³. The binding of pyridoxal in the fresh whole plasma may therefore have been complete. This binding had already been suggested by our studies on red cell metabolism of B₆, for we found that whether pyridoxal was derived from red cell conversion of pyridoxine or was added directly to blood, the proportion

Fig. 2 Plasma protein binding of the pyridoxal originating from red cell conversion of pyridoxine added to whole blood *in vitro*. Heparinised blood was freshly obtained from a healthy subject and to 5.0 ml was added 2,500 ng ³H-pyridoxine (0.05 ml). The mixture was incubated for 2 h at 37° C in a shaking water bath kept in subdued light, after which the blood was centrifuged and the plasma removed. Gel filtration of 2.0 ml of the plasma (containing 520 ng ³H-pyridoxal as measured by microbiological assay and no residual ³H-pyridoxine) was carried out as described in the text for the other experiments, and the ³H-radioactivity (●—●), B₆ microbiological activity (○—○) and protein content (.....) of selected fractions were measured.

Fig. 1 Binding of a, pyridoxine; b, pyridoxal-P and c, pyridoxal to plasma protein. Gel filtration on Sephadex G200 of each compound added *in vitro* either to plasma (●—●) or to saline (×—×). Vitamin B₆ compounds detected either by ³H-radioactivity (pyridoxine) or microbiological assay (pyridoxal-P and pyridoxal). Protein determined by absorbancy at 280 nm (.....).

of pyridoxal in plasma was directly related to the amount of plasma present. In normal blood the proportion was approximately half that in the red cells, but if experimentally a constant volume of red cells was suspended in increasing saline dilutions of plasma, then the proportion of pyridoxal in the supernatant decreased; if plasma was totally replaced by saline or phosphate buffer, all the pyridoxal was accumulated in the red cells, confirming the work of Yamada and Tsuji⁶. It is probable therefore that the binding of pyridoxal to albumin in plasma plays an important part in the distribution of pyridoxal between the red cells and plasma.

Some additional mechanism must, however, be involved to explain the accumulation in red cells of pyridoxal when plasma is replaced by saline. Furthermore, the uptake of pyridoxal by red cells has been shown to be related to the volume of red cells, provided that the volume of plasma is kept constant (B. B. A., unpublished observations). These findings suggest that the distribution of pyridoxal between red cells and plasma may be controlled by competing binders in these compartments.

Further studies of the binding of vitamin B₆ compounds to plasma and to red cell components are being carried out with a variety of techniques in an attempt to confirm the identity of these binders and their significance.

The effect of environmental lighting on porphyrin metabolism in the rat

THE direct action of light on the skin in porphyria is well documented. There is a specific spectral response in that light of wavelengths between 400 nm or 500-600 nm causes lesions through photodynamic action of porphyrin in the skin¹⁻⁴. Light may however affect abnormal porphyrin metabolism apart from any action on the skin. We noticed that skin lesions were provoked in porphyric rats, whose coats were shaved, by continuous irradiation by white light fluorescent tubes. Some porphyric animals, in which the coat was not shaved off as a control, excreted more porphyrin when under continuous light than other control animals under continuous dark. This implicated light as an environmental factor effecting porphyrin metabolism. Porphyrin excretion as a measure of abnormality, however, gave inconclusive results. Instead we have used the activity of hepatic δ -aminolaevulinic acid synthetase (ALA-S), the rate controlling enzyme in the haem biosynthetic pathway⁵, as an index of porphyrin abnormality. Normally, ALA-S activity is low, but where porphyria is present clinically or has been induced chemically in experimental animals, activity is raised⁶. We used 1, 4-dihydro-2, 4, 6-trimethyl pyridine-3, 5-dicarboxylate (DDC) to induce porphyria; this chemical, like some other porphyrinogenic agents, such as griseofulvin, probably acts through interfering with a negative feedback inducing mechanism involving haem⁷.

The ALA-S assay was performed on whole liver homogenates⁸ from Sprague-Dawley rats weighing 200-300 g. We first found that normal rats taken straight from the animal house, after life-long exposure to natural cycles of night and day, had a mean value for hepatic ALA-S activity of 26.09 nmol ALA per g wet weight per h (s.d. \pm 7.68). The effect of exposure on six males and six females to continuous light for 11 d, or on six males and six females to continuous dark to 11 d, made no significant difference to ALA-S activity. This was not so, however, when porphyria was induced by DDC. Our final regime, which we shall call the light-dark-DDC regime, was as follows: days 1-8, food (FFG) (M) and water *ad libitum*; day 9, food and water *ad libitum* and DDC; day 10, food

Table 1 Effect of light on rat hepatic ALA-S activity

	Male		Female	
Light + DDC	94.18 \pm	51.16 (16) }	263.50 \pm	143.28 (16) }
Dark + DDC	63.78 \pm	33.82 (18) }	109.89 \pm	77.62 (17) }

Mean ALA-S activity expressed in nmol per g wet weight per h \pm 1 s.d. Numbers in brackets are the numbers of animals. * Difference between light and dark treated, by *t* test, $0.05 > P > 0.02$. † Difference between light and dark $P < 0.001$.

and water *ad libitum* and DDC; day 11, hepatic ALA-S assay. The rats were kept either in continuous light or dark for 11 d.

The light source was an array of eight parallel 20 W Atlas "white" fluorescent tubes, luminous flux approximately 1,000 lumens each, placed 25 cm above the cage floor containing six rats. The conditions of those animals kept in the dark were of photographic dark-room standard and the animals were only exposed to a few minutes of weak red light each day. The DDC was given by oesophageal tube as a 20% (w/v) suspension in arachis oil at a dose of 400 mg per kg body weight once daily on days 9 and 10.

In the light-dark-DDC regime, continuous light led to increased ALA-S activity compared with continuous darkness; this was more pronounced in the female than in the male (Table 1). Control experiments in which rats were given arachis oil, without DDC, showed no difference in ALA-S activity between light or dark treatment. A preliminary experiment of similar design using mice and griseofulvin as the porphyrinogenic drug, gave the same results as for DDC; increased ALA-S activity by light; but the remaining experiments we report are confined to the female rat and DDC.

To see if the stimulus for the above result might originate in the retina, we investigated the effect of orbitectomy. The difference in ALA-S activity previously found in intact animals was now abolished (Table 2a). Activity to hepatic ALA-S in the light-treated orbitectomised group, however, differed significantly from that in the light-treated unoperated female group (Table 1).

Oestrogens are known to be porphyrinogenic⁹, so we examined the effect of ovariectomy on rats in the light-dark-DDC regime. Again the difference between light and dark on hepatic ALA-S activity was abolished (Table 2b).

As the pineal gland has been implicated in the control of the reproductive system of the rat¹⁰, we next investigated the effect of pinealectomy. Sham operated controls had part

of the calvarium and pia mater overlying the pineal gland removed but the gland was left intact and the wound sutured. In one group of pinealectomised rats, the light-dark-DDC regime was started 7 d later, in another group 100 d after operation. (In the latter group, body weight range was 300–400 g). The results in Table 2c show no significant difference between pinealectomised animals, whether kept in the light or the dark, or whether pinealectomy was 7 d or 100 d before the light-dark-DDC regime.

In rats, intact visual pathways are necessary for normal pineal activity and ovarian development^{8,9}, so light may act on haem biosynthesis in the liver *via* the retina, pineal and gonad. Preliminary results suggest that cycles of 8–12 h light and 16–12 h dark in the light-dark-DDC regime have much the same effect on ALA-S activity as continuous light compared with continuous dark, so that our results may be due to circadian fluctuations in some enzyme or other substance acting in the presence of oestrogen.

Coproporphyrin has been demonstrated in the nervous system of birds¹⁰, where it may play a part in the connection between photoperiodicity and reproductive function.

Continuous darkness or continuous light has been shown¹¹ to alter the activity of two hepatic enzymes in rats, hexobarbital oxidase and *p*-nitroanisole-O-demethylase. We now add evidence that abnormal hepatic metabolism may be under photic influences. The possible influence of environmental lighting on human hepatic porphyria should therefore be borne in mind, although there is so far no evidence for it.

Fig. 1 Effects of aminophylline on the anti-sheep erythrocyte response *in vitro*. Spleen cells from normal CBA/J mice were cultured in Eagle's minimal essential medium containing 10% foetal calf serum, in the presence of 0.01% sheep erythrocytes (SRBC). Each culture initially contained 20×10^6 spleen cells, and was carried out in triplicate in the Diener-Marbrook culture system^{12,13}. At the end of the exposure to aminophylline, the cells were washed by centrifugation, and taken up in fresh medium for further culturing in the presence of antigen. Anti-sheep erythrocyte AFC were determined at 120 h by the method described elsewhere¹⁴. The control cells (no aminophylline) were in each case handled the same way as the experimental cultures. Numbers in parentheses indicate the viable cells, in millions, per culture at 120 h. There was no adjustment of cell numbers after exposure to aminophylline. Shaded columns: cells + medium + 0.01% SRBC + 1 mM aminophylline; unshaded columns: cells + medium + 0.01% SRBC.

mediator of immune induction. But the same agents, at higher than optimal levels, can inhibit the AFC response^{1,3}. Experiments have been done suggesting¹ that enhanced intracellular cyclic AMP is a mediator of immune paralysis, or tolerance. The apparently contradictory conclusions drawn from these various experiments may be resolved if one considers a common kinetic feature of cyclic AMP responses to various agents, in lymphoid⁶⁻⁸ and in non-lymphoid^{9,10} cells; namely, that the rise in cyclic AMP level is transitory, and the cyclic nucleotide level returns to control values after a few minutes or hours. A similar transient rise in cyclic GMP has been noted in phytohaemagglutinin-stimulated peripheral leukocytes, where this nucleotide seems to mediate the blastogenic response to the mitogen¹¹. Thus, the same agents which might enhance an AFC response if present during the increased cyclic AMP phase, could inhibit the response if present during the subsequent phase of declining intracellular cyclic AMP. To see if this pattern was in fact part of an immune response *in vitro*, we performed experiments with sheep erythrocytes as immunising antigen, and varied the time of exposure of the immunocompetent cells to the agents N⁶, 2'-O-dibutyl cyclic AMP or aminophylline. When present only during the first 12 or 24 h of exposure to antigen, these

Biphasic effect of cyclic AMP on an immune response

AGENTS which enhance intracellular adenosine 3', 5'-monophosphate (cyclic AMP) levels⁶ by inhibiting cyclic AMP phosphodiesterase activity can increase the number of antibody forming cells (AFC) in humoral immunity both *in vivo*^{1,2} and *in vitro*^{3,4}. Thus, cyclic AMP is a potential

Table 1 Stimulatory effect of dibutyryl cyclic AMP requires that antigen be present

Additives during first incubation (0-12h)	Viability after first incubation	Viable cells on day 4, $\times 10^{-6}$	Anti-SRBC AFC on day 4
SRBC only	98%	3.3	3,940 \pm 270
SRBC + 1mM dibutyryl cyclic AMP	73%	4.1	16,990 \pm 770
Medium only	91%	3.4	3,000 \pm 440
1 mM dibutyryl cyclic AMP	68%	4.1	3,100 \pm 200

Conditions of culturing and assay were as indicated in Fig. 1, except that the first incubation only was performed in 60×15 mm plastic Petri dishes. Each culture was adjusted to contain 14×10^6 viable spleen cells after the first incubation.

agents increased the number of AFC seen after 4 or 5 d of culture. But they inhibited the response if present during days 2 or 3. The effects of increasing intracellular cyclic AMP during the early period were twofold: (1) there was a delay in the arrival of cells at the antibody-secreting stage, and (2) the number of AFC at the optimal time was increased.

Anti-sheep erythrocyte responses were generated *in vitro*, using unprimed spleen cells from CBA/J mice. Cells and antigen were incubated with various agents for different times, the cells were washed, and the AFC response measured after further culturing with antigen alone. The biphasic effect of aminophylline is shown in Fig. 1. When present only for the first 24 h at 1 mM this agent enhanced the AFC response observed on day 5 of culture. But it strongly inhibited the response if it was present at the same concentration for 24 h periods between 24 and 96 h. Similar patterns were observed with dibutyryl cyclic AMP. Neither agent had a significant effect if present only on the last day of culturing. The stimulatory level of both agents was 1 mM.

The stimulatory effect of dibutyryl cyclic AMP was observed only when antigen was also present (Table 1). In this experiment, cells were exposed to dibutyryl cyclic AMP for the first 12 h, which produced a stimulation of the AFC response comparable to that observed after 24 h exposure to aminophylline or dibutyryl cyclic AMP. The stimulation was observed only if antigen was present simultaneously with the agent. In this experiment, as in the others described, the effects can be seen not to arise from differences in gross cell viability.

We next examined the kinetics of the AFC response following a 12 h pulse of either aminophylline or dibutyryl cyclic AMP. Cells were exposed to antigen and optimal levels of either dibutyryl cyclic AMP or aminophylline for 12 h, washed, and cultured further with antigen alone. The numbers of AFC were determined at various times. During the first 2 d of culture, fewer AFC were found in the treated cultures than in controls. At later times, the number of AFC increased rapidly to as much as six times control values (Fig. 2). Aminophylline and dibutyryl cyclic AMP gave identical results, suggesting that they function identically, by inhibition of cyclic AMP phosphodiesterase(s). This is the accepted mode of action of aminophylline, and as other data suggest, of dibutyryl cyclic AMP as well¹⁵.

Our data thus suggest that cyclic AMP plays a positive role in the first phase of an immune response, which is the commitment of an antigen-reactive cell to the expression of its specialised function. In the second phase, which begins around 24-36 h, proliferation occurs¹⁶. Since cyclic AMP seems to be antimitotic in lymphocytes as in other cultured cells^{17,18}, one should expect that inhibiting cyclic AMP phosphodiesterase activity at this time would inhibit the onset of proliferation. It has in fact been observed that the cyclic AMP levels in synchronised lymphocytes are highest in G1 and G2 phases, and at S phase and mitosis the levels are only about 20% of the G2 level¹⁷. This model is consistent with the day 2 and day 3 inhibitory effects that we observed. Other work suggests that the proliferative phase may depend

on elevated cyclic GMP levels^{11,18}, and that the two cyclic purine nucleotides vary inversely.

Watson *et al.*⁵ have demonstrated a time dependent, antigen independent inhibitory effect of dibutyryl cyclic AMP on immunocyte functioning. An interesting observation was that cyclic GMP reversed the cytotoxic effects of dibutyryl cyclic AMP. We also observed cytotoxic effects of incubating cells with dibutyryl cyclic AMP (Table 1) but

Fig. 2 Kinetic analysis of the effects of cyclic AMP phosphodiesterase inhibitors on the anti-sheep erythrocyte AFC response. Spleen cells were exposed to the agents indicated for the first 12 h in 60×15 mm Petri dishes. They were then transferred to the usual Diener-Marbrook culture flasks, and cultured in quadruplicate until the times indicated. Each culture was adjusted to contain 11×10^6 viable cells at the end of the 12 h period. Because of lower viability in treated cultures (Table 1), these represent 30-40% more starting cells than do the controls. The numbers in parentheses indicate the number of viable cells, in millions, per culture at day 5. Vertical bars give the standard errors of the means for the control and dibutyryl cyclic AMP treated cultures (the aminophylline treated values had similar standard errors to the latter) (●) untreated cells, given the same wash and incubation procedure; (Δ) cells treated with 1 mM dibutyryl cyclic AMP for 12 h first; (▲) cells treated with 1 mM aminophylline for the same period. Antigen was present throughout the culture period, including the first 12 h, in all flasks.

these were smaller than the effects reported by Watson *et al.*, perhaps because of differences in cells (C57BL/6 compared with CBA/J) or culture conditions. At any rate, they were not large enough to obscure our key finding, the antigen dependent stimulatory effect of cyclic AMP phosphodiesterase inhibitors at early times of immune induction. Preliminary experiments in our laboratory show that these agents act in a similar manner on a T cell independent antigen, the polymerised flagellin from *S. adelaide*. Our conclusions agree with those of Watson *et al.* inasmuch as the phase one (commitment) to phase two (proliferation) switch is inhibited by cyclic AMP, but add to them the important observation that an early enhancement of cyclic AMP increases the number of AFC observed at much later times. If the assumption that aminophylline and dibutyryl cyclic AMP elevate intracellular cyclic AMP levels is correct, the present work supports a model of primary immune induction in which a temporally limited rise in cyclic AMP is an early positive signal following antigen recognition. Immune paralysis might follow if the cells concerned were unable to reduce the pulse of cyclic AMP to levels consistent with cell cycling.

A preliminary report¹⁹ describes a similar pattern of effects of cyclic AMP enhancing agents in an *in vivo* immune response to sheep erythrocytes. In that system, an early rise in cyclic AMP appears to be followed by its return to normal levels by 1 h.

An inhibitory effect of exogenously added cyclic AMP on the anti-sheep erythrocyte response *in vitro* has been observed by others²⁰. We have not been able to affect the immune response in any way by adding up to 1 mM cyclic AMP itself to cell cultures. It is perhaps not surprising that at least under some conditions this nucleotide is without effect, since the half life of cyclic AMP in rat thymocyte cultures is less than 30 min, and no exogenously added cyclic AMP enters the cells²¹.

We thank Dr E. Diener for assistance and encouragement, and Drs Rod Langman, Kwok-Choy Lee and Chiaki Shiozawa for discussion. The work was supported by MRC (Canada) grants to the Transplantation Immunology Group and to V.P., and by the National Cancer Institute of Canada.

Plasma cell surface antigen on human blood lymphocytes

THERE is considerable evidence that lymphocytes bearing immunoglobulins on their surfaces are present in the peripheral blood of various animal species as well as man¹⁻³. Takahashi *et al.*⁴ indicated that neoplastic, as well as normal mouse plasma cells, contained specific surface alloantigens. These plasma cells do not, however, contain surface immunoglobulin determinants⁵. Harris *et al.*^{6,7} demonstrated that neoplastic plasma cells of the mouse could be used to prepare specific antisera against normal plasma cells. These anti-plasma cell sera (APS) were found to suppress specifically primary and secondary humoral immunity without apparently affecting cellular immunity. Recently, we established a long term culture of human plasma cells⁸ from a localised plasmacytoma tumour of a patient with multiple myeloma. The cultured cells morphologically resembled plasma cells, and they secreted an IgG immunoglobulin antigenically identical to the patient's myeloma protein. Using cells from this source, an anti-human plasma cell serum (HuAPS) has been prepared which recognises a surface antigen on human plasma cells.

Human plasma cells from the long term cell line⁸ were injected into rabbits in the same manner as in the prepara-

Table 1 Effect of APS on mitogenic response of human lymphocytes

Cells and PWM	9	175,427	
Cells and PWM and APS	5	97,325	45

tion of rabbit anti-mouse plasma cell sera^{6,7}. The HuAPS was absorbed extensively with lymphoblast cell line RPMI 4098, which was chosen because it has been used for the preparation of anti-human lymphocyte globulin with potent T lymphocyte immunosuppressive activity⁹. Immunoabsorbents were used to purify the HuAPS further. The HuAPS was passed through an immunoabsorbent column prepared by conjugating human immunoglobulins to Sepharose 4B by cyanogen bromide activation.

Ten to twenty millilitres of venous blood was collected from each subject, all of whom were laboratory personnel. Ficoll-Hypaque density centrifugation, as modified from Boyum¹⁰, was used to prepare a relatively pure population of lymphocytes. In some cases, contaminating red cells were lysed by Tris-buffered ammonium chloride.

Human peripheral blood lymphocytes were cultured by the micro method of Hartzman *et al.*¹¹ using 2×10^5 lymphocytes per well in Falcon microtest plates. AB+ serum was used in a 25% concentration with HEPES-buffered RPMI 1640 media. Cells were either incubated

alone, with phytohaemagglutinin (Difco, PHA-P, No. 3110-56, 2 λ per culture); with pokeweed mitogen (Gibco, PWM, No. 536, 2 λ per culture), with PHA plus HuAPS, or with PWM plus HuAPS. The concentration of HuAPS was 2 λ per culture. This was observed to be noncytotoxic. After 4 d of growth, 1 μ Ci of 3 H-thymidine (specific activity 1.9 Ci mmol $^{-1}$) was added to each culture. Quintuplicate cultures from each donor were collected 4-6 h later using glass fibre filter paper precipitation. Filter disks were counted in a Packard Tri-carb liquid scintillation counter. The uptake of 3 H-thymidine was expressed as c.p.m. Table 1 shows that HuAPS had no effect on human peripheral blood lymphocyte response to PHA, a known T-lymphocyte mitogen^{12,13}. HuAPS, however, depressed the PWM response approximately 45%. This was significant for the following reasons. (a) PWM is a mitogen for both T and B lymphocytes. (b) Cells which appear morphologically to be plasma cells form after PWM stimulation. (c) Immunoglobulin synthesis is enhanced by PWM (refs 13, 14). Therefore, it seems likely that HuAPS in the study reported here was blocking a B lymphocyte response.

Fig. 1 The membrane staining characteristics of human peripheral blood lymphocytes and cultured lymphocytes from the same individual. Dotted columns, normal peripheral blood lymphocytes; solid columns, control *in vitro* culture; hatched columns, PHA *in vitro* culture; open columns, PWM *in vitro* culture.

Blood lymphocytes with membrane-bound immunoglobulins or with membrane-bound plasma cell antigen were detected by immunofluorescence¹. Cells with membrane-bound immunoglobulin were enumerated by using fluorescein-conjugated goat anti-human IgG, goat anti-human IgM and goat anti-human IgA (all from Cappel Laboratory). Before use, these conjugates were absorbed with cell line RPMI 4098 and with cultured plasma cells. These conju-

gated antisera were then diluted 1:2 and used to stain blood lymphocytes directly. Those used in double-labelling studies with the HuAPS were also absorbed with rabbit sera. For the enumeration of plasma cells, indirect fluorescent staining was used, with either fluorescein or rhodamine-conjugated goat anti-rabbit IgG (Cappel Laboratory). Both conjugated goat anti-rabbit preparations were purified by passage through an immunoabsorbent column conjugated with human serum, and by absorption with human peripheral blood lymphocytes.

To ensure that the HuAPS did not react with membrane-bound immunoglobulins, a blocking experiment was performed. The lymphocytes were incubated with unlabelled goat anti-human immunoglobulins before staining with rabbit anti-human plasma cell serum (HuAPS) and fluorescein-conjugated goat anti-rabbit IgG. In addition, double-labelling studies were performed in which the cells were treated sequentially with HuAPS, rhodamine-conjugated goat anti-rabbit IgG and fluorescein-conjugated goat anti-human IgG, IgM or IgA. Because of a possible peculiarity of the surface binding sites, the order of the procedure was reversed. Fluorescein-conjugated goat anti-human IgG, IgM or IgA was used first, followed by unlabelled HuAPS, and then by a rhodamine-conjugated goat anti-rabbit IgG.

The frequency of blood lymphocytes with membrane-bound immunoglobulins from normal individuals was similar to those reported previously^{2,15} (Table 2). It was also found that the number of lymphocytes with membrane-bound immunoglobulins in PHA or PWM-treated cultures either remained unchanged or decreased. Approximately 12% of peripheral blood lymphocytes had the plasma cell antigen. Ring staining and cap staining patterns were observed for both surface immunoglobulins and the plasma cell antigen. During the mitogenic response of human peripheral blood lymphocytes to PWM, there was an increase in the number of cells exhibiting the plasma cell surface antigen (Table 2). Figure 1 is a representation of an individual's typical membrane-staining distribution for immunoglobulins and plasma cell antigens on lymphocytes which were or were not exposed to mitogens.

The relative frequency of fluorescein-stained cells did not change when the cells were pretreated with unlabelled goat anti-human immunoglobulin. From the double-labelling studies, no cell was found with both the plasma cell surface antigen and the membrane-bound immunoglobulin. Therefore, I concluded that the plasma cell antigen did not cross react immunologically with surface immunoglobulin molecules. The blocking and double-labelling studies also support the concept that the plasma cell antigen is a distinct antigen on the surface of a significant number of peripheral blood lymphocytes; however, it is not known whether the antigen is expressed on nonlymphoid cells.

The observations of Takahashi *et al.*⁴ and Harris *et al.*^{6,7} led to the assumption that neoplastic human plasma cells could have antigens in common with normal human plasma cells. My study indicates that an anti-human plasma cell serum prepared against cultured human neoplastic plasma cells seems to have antibody activity against some normal human blood lymphocytes. (a) Stimulation with PWM, an agent which affects B and T lymphocytes^{13,14} was depressed

to the same extent that rabbit anti-mouse plasma cell sera modified the mouse system (unpublished observations), whereas, stimulation with PHA, a mitogen which affects primarily T lymphocytes^{12,13} was not affected. (b) Immunofluorescent examination showed that a population of blood lymphocytes had the plasma cell antigen, even though these cells do not resemble plasma cells morphologically. This is not surprising, however. Previous studies⁸ demonstrated that cultured plasma cells in spinner culture maintain the morphology of lymphoblasts. When transferred to Falcon tissue culture flasks, they assumed the typical configuration of plasma cells. Thus motion seemed to change the cultured plasma cell from a lymphoid appearance to a typical plasma cell morphology. Circulating plasma cells may not be recognised in multiple myeloma. Most patients examined had 90% or more plasma cells in their bone marrow. It is rare to find morphologically typical plasma cells in their peripheral blood, but metastatic plasma cell lesions are common.

As well as finding circulating blood lymphocytes with a plasma cell antigen, I have demonstrated that cells bearing the plasma cell antigen increased as a result of PWM stimulation. Since the number of immunoglobulin-bearing cells either decrease or remain the same in such cultures, it seems possible that the plasma cell surface antigen could develop as a consequence of stimulation of a certain population of B lymphocytes. This might suggest that the immunoglobulin-bearing cells are precursors of plasma cells. Future studies must examine the relationship between cytoplasmically stained immunoglobulin-containing cells and those cells bearing the plasma cell antigen on their surfaces. Another possibility is that plasma cell precursors migrate from the bone marrow into the peripheral blood. These blood-borne cells are then influenced to undergo further morphological changes and functional differentiation in the microenvironment of the peripheral lymphoid tissue and are consequently recognised as plasma cells.

Linkage and rearrangement of genes encoding mouse immunoglobulin heavy chains

THE study of the genetic control of immunoglobulin synthesis has been greatly hampered by the difficulty of detecting individual genes encoding variable regions (*V* genes). The distinction by allotypy of several *V*-gene loci in the rabbit is useful, but genetic studies on this species have obvious disadvantages. The discovery in inbred mice of crossreactive idiotypes^{1,2} and of their polymorphic expression³⁻⁶ allows a new approach to the genetic analysis of mouse immunoglobulins. The results presented here suggest that idiotypes may serve to distinguish individual *V*-gene loci within the mouse heavy chain linkage group and to detect recombinations between them.

We have investigated linkage relationships between two mouse antibody idiotypes, termed ARS (ref. 3) and A5A (ref. 4), both of which are linked to the strain A/J *C_H* allotype Ig-1.e (refs 7-9). Idiotypic ARS is associated with antibodies to the *p*-azophenylarsonate hapten, produced in all A/J mice^{3,7} whereas idiotypic A5A is associated with antibodies to Group A streptococcal carbohydrate (A-CHO), produced in 94% of A/J mice^{4,8}. It is therefore proposed that strain A/J antibodies to these antigens are at least in part controlled by the *V_H* gene loci *ARS*+ and *A5A*+, respectively. Strain BALB/cJ (Ig-1.a) antibodies to both antigens lack these idiotypes^{7,8}. As was expected from the previously established linkage of each of the idiotypes to the same *C_H* allele^{7,9}, the results confirm that the two idiotypes are specified by linked genes.

We were fortunate to encounter a backcross mouse which was phenotypically suggestive of a recombination between A/J *V_H* genes and BALB/cJ *C_H* genes⁹. This permitted us to investigate whether or not *ARS*+ and *A5A*+ map at the same position within the A/J heavy chain linkage group. The backcross mouse, referred to as BB δ 7, was identified as the only A5A positive mouse among 16 Ig-1.a/a homozygous progeny from an (A/J \times BALB/cJ)F₁ \times BALB/cJ mating⁹. The association of the A5A idiotypic with the Ig-1.a allotype, suggesting a new linkage of *A5A*+ with Ig-1.a, has not been observed among more than 100 BALB/cJ mice, and has not been found again among 57 additional backcross segregants tested.

We ascertained the allotype and the presence or absence of two idiotypes in individual mice. Allotypes were determined

by agar diffusion analysis using antisera prepared by cross immunisation between strains A/J and BALB/cJ (ref. 10), as previously described⁹. The determination of idiotypes ARS and A5A used indirect radioprecipitin inhibition tests, using rabbit anti-idiotypic antisera for ARS (ref. 3) and guinea pig anti-idiotypic antisera for A5A (ref. 8), respectively. Hyper-immune serum samples were tested for inhibitory capacity in at least three dilutions. Antibodies to A-CHO were determined by a modified Farr assay⁴ and the presence of antibodies to the *p*-azophenylarsonate group was determined by agar diffusion analysis⁸.

First we had to establish that A/J antibodies to phenylarsonate do not idiotypically crossreact with A/J antibodies to A-CHO and *vice versa*. Sixteen individual anti-phenylarsonate antisera were tested for their capacity to inhibit A5A idiotype binding and 19 individual anti-A-CHO antisera were tested for their capacity to inhibit ARS idiotype binding. Whereas each of these antisera was strongly inhibitory of its corresponding idiotype binding system, less than 10% inhibition was obtained in the heterologous idiotype binding systems, using up to 20 μ l of each undiluted antiserum. This shows the absence of idiotype cross reactivity between strain A/J antibodies to phenylarsonate and to A-CHO, respectively, and enabled us to determine both idiotypes in individual mice which were successively immunised with both antigens.

‡56% inhibition with 10 μ l of antiserum, doubtful typing.

In a second experiment, a number of (A/J \times BALB/cJ) F_1 \times BALB/cJ backcross mice, which will be referred to as ABB mice, were tested for allotype and for both idiotypes. ABB mice were bred in Cologne from A/J and BALB/cJ mice which were obtained from the Jackson Laboratory, United States. At 8–10 weeks of age the mice were bled and allotyped. Subsequently, the mice received one course of injections with Group A streptococci⁴. The anti-A-CHO antisera resulting from this immunisation were allotyped and then idiotyped in the A5A idiotype binding inhibition assay. After 8–10 weeks, the mice were immunised with KLH-*p*-azophenylarsonate as previously described³. The anti-phenylarsonate antisera resulting from this immunisation were allotyped and then sent to Chicago for idiotyping in the ARS idiotype binding inhibition assay. All experiments were done blind; the source and allotype

†These mice were given to us by Drs M. Potter and E. Mushinsky, N.I.H.

of transferred serum samples were unknown to the investigator performing idiotype analysis.

Table 1 shows the results from allotyping and idiotyping 19 ABB mice. Among three successive allotype determinations on each mouse no discrepancy was observed, so that the allotypes can be taken as a true reflection of the C_H genotype for each mouse. All 11 *Ig-1.a/e* heterozygotes express ARS as well as A5A, whereas all eight *Ig-1.a/a* homozygotes express neither of the two idiotypes. This confirms the linkage between ARS+, A5A+ and *Ig-1.e* in the A/J heavy chain linkage group. The question remains as to whether ARS+ and A5A+ are controlled by a single gene or by different genes.

Therefore, in a third experiment, progeny of a BB β 7 \times BALB/cJ mating were allotyped and idiotyped in the same way as were the ABB mice. We included as a control another litter from the same BALB/cJ female sired by BB β 1, an *Ig-1.a/a* homozygous, but A5A negative (that is non-recombinant) brother of BB β 7 (ref. 9). The results are shown in Table 2. All of the 13 offspring from BB β 7 were *Ig-1.a/a* homozygous, confirming the *Ig-1.a/a* homozygosity of BB β 7. Six of the 13 mice clearly expressed idiotype A5A and thus had inherited the A5A+ - *Ig-1.a* haplotype of BB β 7. Seven of the 13 mice were A5A negative and had inherited the A5A- - *Ig-1.a* haplotype of BB β 7. In contrast, with one doubtful exception, all of the 13 mice were negative for the ARS idiotype, suggesting that the A5A+ - *Ig-1.a* haplotype does not contain the ARS+ gene. The data on the BB β 1 offspring confirm that the A5A+ - *Ig-1.a* haplotype was indeed inherited from BB β 7.

The results are consistent with the view that, in the heterozygous parent of BB β 7, A5A+ was separated by crossover from ARS+ as well as from *Ig-1.e*, and became linked by recombination to *Ig-1.a* of the BALB/cJ chromosome. In this case, ARS+ would map between A5A+ and *Ig-1* and the crossover had occurred between two distinct V_H gene loci. The alternative explanation is a mutation in the BALB/cJ V_H genes from A5A- to A5A+, without ARS- being affected. Such a mutation occurring in one cistron encoding both A5A- and ARS- V_H regions would be unlikely. Therefore, in the case of a mutational event, the data would be indicative of multiple V_H gene loci in strain BALB/cJ.

Though a mutational event is not ruled out, the case for two different germ line V_H gene loci for ARS+ and A5A+ is supported by the association of ARS+ and A5A+ antibodies with several distinct *Ig-1* genotypes (Table 3). Strain AL/N and its *Ig-1* congenic strain CAL-20 express ARS+ but do not express A5A+, whereas strains A/J and A/He express both idiotypes, and strain RF/J expresses A5A+ only¹¹. The separate as well as joint expression of these idiotype markers in different inbred strains, together with their dissociation in the BB β 7 progeny, strongly suggests that A5A and ARS map at different positions in the mouse heavy chain linkage group, and thus represent separate gene loci.

This seems to be the first demonstration of two distinct germ line V_H genes controlling distinct antibody specificities. The data suggest that the establishment of recombinant inbred strains from mice such as BB β 7, and their investigation with multiple idiotype markers, may reveal considerable information on the chromosomal arrangement of antibody genes.

Interaction of paramyxovirus with erythrocyte membranes modified by concanavalin A

THE envelopes of paramyxoviruses have neuraminidase, haemagglutinating, haemolytic and fusion activities¹⁻⁶. The interrelation of these activities is poorly understood.

Burnet and Lind⁷ studied the interaction of Newcastle Disease virus with several species of mammalian and avian erythrocytes and found most of the cells susceptible to haemagglutination and haemolysis except horse erythrocytes, which agglutinated poorly and resisted haemolysis by the virus. Horse erythrocytes are also not susceptible to haemagglutination by Haemagglutinating Virus of Japan (HVJ: Sendai virus) (refs 8-10 and our own observations). It can be assumed that horse erythrocytes have no specific receptor for the viral haemagglutinin and/or haemolysin¹¹.

Yamakawa¹² reported that horse erythrocytes had no detectable amounts of N-acetyl-neuraminic acid either in the glycolipid fraction or in the residue extracted extensively with organic solvent. Instead, they were found to contain N-glycolyl-neuraminic acid exclusively. It is well known that erythrocytes from which the neuraminic acid residue is removed by the action of the so-called receptor destroying enzyme (neuraminidase) are completely resistant to agglutination and haemolysis by myxo and paramyxoviruses. These facts clearly indicate that the receptor for the viruses contains the neuraminic acid residue. N-glycolyl-neuraminic acid may not have a role as a virus receptor.

The initial interaction of virus with host cell membrane may be that between viral haemagglutinin and the receptor containing N-acetyl-neuraminic acid. It is not known whether this binding of the virus with host membrane is essential for the subsequent haemolysis or fusion. It would be of special interest, therefore, if HVJ proved to have haemolytic activity when the virus was artificially adsorbed on horse erythrocytes. In this report, we shall show that horse erythrocytes treated with concanavalin A (con A) are able to interact with HVJ and to be haemolysed.

Fig. 1 Adsorption (Δ) and haemolytic activity (O) of HVJ to horse erythrocytes treated by various concentrations of con A. Aliquots of con A solution were mixed with equal volumes of 2% horse erythrocyte suspension in phosphate-buffered saline (pH 7.2). The concentration of con A added was expressed as final concentration. After the treatment with con A at 0° C for 4 h, whole mixtures were directly used without washing, since non-reacting free con A was not detected at the doses used through the present experiment. For the adsorption experiment, 0.1 ml of the virus suspension (4,000 HA per 0.5 ml) was mixed with 0.9 ml of intact and con A-treated horse erythrocytes. After incubating for 2 h at room temperature, HA titre remaining in the supernatant of centrifugation (1,500g, 5 min) was determined. For the haemolysis experiment, 0.5 ml of the same virus suspension (10,000 HA per 0.5 ml) was mixed with 0.5 ml of the same preparation of con A-treated cells as used in the adsorption experiment. After incubation of the mixtures for 2 h at 36° C, the optimum density of clear supernatant obtained by centrifugation (1,500g, 5 min followed by 80,000g, 15 min) was determined photometrically (at 541 nm). Control lysis of con A-treated horse erythrocytes without HVJ was also determined (—●—). Activities were expressed as a percentage of original HA titre or complete haemolysis obtained by hypotonic treatment.

HVJ was highly purified by differential centrifugation, sucrose density gradient centrifugation and finally by gel filtration through a Sepharose 2B column. Fractions in void volume were collected. The pooled fractions were finally concentrated in a reduced volume of phosphate-buffered saline by pelleting at 60,000g for 30 min. The viral sample was exposed to freezing-thawing two or three times to activate the haemolytic activity¹³. The treatment of horse erythrocytes with con A is described in Fig. 1. Horse erythrocytes were purchased as stored blood and used within 3 weeks. The haemagglutinating titre (HA) was routinely determined with chicken erythrocytes. The degree of adsorption of HVJ on con A-treated horse erythrocytes was estimated by titration of the HA remaining in the supernatant after the incubation mixture was centrifuged at low speed. An aliquot of the suspension of con A-treated horse erythrocyte (0.9 ml) was incubated with 0.1 ml of HVJ (4,000 HA per 0.5 ml) for 2 h at room temperature. Haemolytic activity of the virus was assayed as follows: an adequate dilution of HVJ and the same volume of con A-treated horse erythrocytes were mixed and incubated at 36° C for 2 h. After the incubation, nonhaemolysed cells were removed by sedimentation at 1,500g for 5 min. The supernatant thus obtained was further centrifuged at 80,000g for 15 min to remove viral particles. Haemolysis was measured by reading optical density at 541 nm of the final supernatant. For the inhibition experiment of virus-induced haemolysis by sugars, the mixture containing con A-treated horse erythrocytes

Fig. 2 Haemolysis of con A-treated horse erythrocytes by varying titres of HVJ. Viruses (32,000 HA per 0.5 ml) were diluted with the phosphate-buffered saline by twofold serial dilution of 0.5 ml. Horse erythrocytes were treated with con A at the final concentration of $1 \mu\text{g ml}^{-1}$. Suspensions of con A-treated horse erythrocytes (0.5 ml) were added to each dilution of the virus and haemolysis was assayed by the same procedure as in Fig. 1.

and a monosaccharide was preincubated at 4°C for 30 min. Adequate dilutions of HVJ were added to the mixture and further incubated at 36°C for 2 h. The haemolysis was assayed as described above. A plasma membrane fraction was prepared from intact and con A-treated horse erythrocytes by hypotonic haemolysis. The membrane pellets finally obtained were resuspended in a small volume of phosphate buffered-saline. For the electron microscopic observation, samples were negatively stained with phosphotungstate (pH 6.0).

The adsorption of HVJ on con A-treated horse erythrocytes and the subsequent haemolysis are shown in Fig. 1.

Fig. 3 Inhibitory effect of monosaccharides on haemolysis of con A-treated horse erythrocytes by HVJ. Horse erythrocytes were treated with con A at the final concentration of $1 \mu\text{g ml}^{-1}$ as described in the legend to Fig. 1. Con A-treated cells (0.5 ml) were mixed with 0.25 ml of solutions containing various amounts of (○), α -methyl-D-mannoside; (△), α -methyl-D-glucoside; (×), D-mannose. After incubating the mixtures at 4°C for 30 min, 0.25 ml of HVJ suspension (10,000 HA per 0.5 ml) was added. Haemolysis was assayed after incubating 2 h at 36°C . The degree of inhibition was expressed as a percentage of the haemolysis without sugars.

Fig. 4 Electron microscopic observation of adsorption of HVJ on plasma membrane derived from intact and con A-treated horse erythrocytes. Con A-treated horse erythrocytes (final concentration of con A: $5 \mu\text{g ml}^{-1}$) were prepared as described in the legend to Fig. 1. Plasma membranes were prepared by the following procedure. Ten millilitres of intact and con A-treated horse cells were diluted in 30 ml of distilled water and sedimented at $1,500g$ for 5 min. The pellets obtained were washed three times with phosphate-buffered saline and were resuspended in 0.1 ml of phosphate-buffered saline. The suspension was mixed with 0.1 ml of HVJ (5,000 HA per 0.5 ml) and the mixture was incubated for 30 min at room temperature. After washing three times with phosphate-buffered saline to remove non-adsorbed virus particles, the samples were stained with phosphotungstate (pH 6.0). a, Plasma membrane from an intact horse cell; b, a con A-treated horse cell. Scale: 1,000 nm.

Intact horse erythrocytes showed negligible interaction with HVJ and were not susceptible to viral haemolysis. With the increase in con A concentration, the HA titre remaining in the supernatant decreased, which indicated that more viruses were adsorbed on the cells. The susceptibility of cells to haemolysis increased in parallel with the increase of adsorption of the virus on the con A-treated cells. The degree of haemolysis reached a plateau at $1 \mu\text{g ml}^{-1}$ con A although higher concentrations of con A caused more HVJ to adsorb on to the cells. The haemolysis was also shown to be dependent on virus doses. The maximum haemolysis was obtained at a titre of 10,000 HA per 0.5 ml (Fig. 2). The control haemolysis of con A-treated horse erythrocytes was almost negligible without HVJ even at the highest concentration of con A (Fig. 1). These results suggest that the haemolysis may be due to the direct action of the HVJ virion on the erythrocyte membrane. Influenza viruses which had no haemolytic activity showed almost the same ability to

bind to con A-treated horse erythrocytes as HVJ, although the cells did not reveal detectable haemolysis. This fact may exclude the possibility that con A treatment makes the cells fragile and enhances nonspecific lysis due to the attachment of viral particles.

The effect of con A on horse erythrocytes described above was shown to be influenced by typical inhibitors of the plant agglutinin (Fig. 3). α -Methyl-D-mannoside showed the most potent inhibitory activity against the virus-induced haemolysis, while α -methyl-D-glucose and D-mannose showed much weaker inhibitory activity. It seems that the inhibition of haemolysis by a monosaccharide results from blocking the adsorption step of virus on to blood cells, since the degree of adsorption of the viruses was affected by those inhibitors (not shown in the figure). The pattern of inhibition by sugars shown here is almost the same as those reported for the aggregation of dextran by con A¹⁴. The reversibility of con A action on the blood cell membranes was also confirmed.

The adsorption of HVJ on con A-treated horse erythrocytes was examined under the electron microscope (Fig. 4). Plasma membranes of con A-treated horse cells could adsorb the viruses on the cell surface whereas those of the intact cells could not. The HVJ virion, once it had interacted, could not be removed even by washing extensively by phosphate-buffered saline. Haemolysis of con A-treated horse erythrocytes by the virus showed a similar characteristic to the haemolysis observed in the system of chicken erythrocytes and HVJ (manuscript in preparation).

The mechanism of the interaction between con A-treated horse erythrocytes and HVJ still remains to be clarified. HVJ may be bound to con A-treated horse erythrocytes through a con A bridge, since con A has polyvalent binding sites in its molecule¹⁵ and virions of HVJ have receptors for con A¹⁶. Alternatively, membranes of horse erythrocytes may acquire some new binding sites for the virus or just reveal buried receptors by combining with con A. This is plausible since con A modifies several membrane functions and structures¹⁷⁻¹⁹. Recent studies in which HVJ was fractionated to subcomponents suggested that the viral haemolysin might be on different molecules from the viral haemagglutinin and neuraminidase. These studies failed, however, to show whether the interaction of the virus with host membranes through the receptor for the haemagglutinin and/or neuraminidase is essential for the expression of haemolysis²⁰.

Our results suggest that haemolysis induced by HVJ does not require the binding of viruses to the specific receptors such as sites for haemagglutinin or neuraminidase on cell surface. Even when HVJ was adsorbed on erythrocytes by a different mechanism the cells were haemolysed

Replication of *Escherichia coli* requires DNA polymerase I

For many years DNA polymerase I was the only known *E. coli* enzyme with the ability to synthesise DNA. It was, therefore, assumed by many to be the enzyme required for DNA replication. Doubts concerning this assumption were taken seriously only when DeLucia and Cairns¹ isolated a viable *E. coli* mutant with less than 1% of the normal polymerase I activity in *in vitro* tests. The conjecture that polymerase I might not be involved at all in replication but only functions in DNA repair processes was soon superseded by the observation that polymerase I is involved in the joining of Okazaki pieces^{2,3}. But the question whether DNA polymerase I is essential for replication or whether it is dispensable enzyme remained open. To investigate whether DNA polymerase I is essential for replication, we attempted the isolation of conditional lethal mutations in the gene coding for polymerase I.

Among many DNA polymerase I mutants of *E. coli* we have isolated one (BT 4113) which is conditional lethal at elevated temperature because of a temperature-sensitive DNA polymerase I. A bacterial culture was mutagenised by N-methyl-nitrosoguanidine and screened for *pol A* mutants using a new replica plating procedure in which microcolonies growing on membranes are tested after lysis *in situ* for their ability to synthesise DNA or to degrade DNA exonucleolytically. This method, which was originally developed for the large-scale isolation of *dna* temperature sensitive mutants will be described in detail elsewhere. Approximately

Table 1 Temperature dependence of polymerising and 5'-exonuclease activity

Strain	Polymerising activity (pmol TTP incorporated μ l ⁻¹)		Assay for 5'-Exonuclease activity (pmol ³² P released)	
	30°C	45°C	30°C	45°C
W 3110	44	140	0.20	0.33
BT 4109	18.3	1.79	0.27	0.31
BT 4113	9.3	0.72	0.16	0.05

DNA polymerase I was partially purified and assayed as described by Lehman and Chien⁴. Sucrose-gradient fractions were prepared and assayed for both polymerase and 5'-exonuclease activity. The polymerising activity was determined at pH 7.5 using calf thymus DNA as a template. The incubation was preceded by a 15-min preincubation under identical conditions. The 5'-exonuclease activity was determined by degradation of 5'-³²P-dTfA over 5 min as described by Lehman and Chien⁴. The activity measured is sensitive to DNA polymerase I antiserum (data not presented).

40,000 lysed colonies from this culture could be conveniently tested for their polymerase I activity at elevated temperature. Those lysed colonies unable either to synthesise DNA at 45° C in the presence of N-ethylmaleimide (NEM) or to degrade DNA exonucleolytically in the presence of NEM at 45° C were detected by autoradiography and the corresponding colonies were isolated from the replica. NEM inhibits many enzymes including DNA polymerase II and III but not polymerase I.

Among 40,000 bacterial colonies of *E. coli* W 3110 (ref. 1) we found 12 mutants with measurable defects in polymerase I activity, some having as little as 1% of wild-type polymerase activity. As expected¹, the mutants were sensitive to methylmethane-sulphonate. Some mutants had a temperature-sensitive DNA polymerase. The temperature dependence of polymerising and 5'-exonuclease activity for two strains is shown in Table 1. The polymerising activity of both strains was temperature sensitive. The 5' exonuclease activity seemed normal in BT 4109 and was temperature sensitive in BT 4113. When exposed to high temperature, bacteria of strain BT 4113 formed snakes and failed to form colonies. BT 4113 is the only conditional lethal mutant we have found.

DNA polymerase I is known to be involved in sealing of Okazaki pieces^{2,3}. According to sedimentation analysis of newly synthesised DNA the mutants tested varied in their ability to join Okazaki pieces, some (for example BT 4004) being almost as efficient as wild type, some (for example BT 4100 being grossly defective in sealing and some (for example BT 4113) being grossly defective in sealing only at elevated temperatures. In the latter strain there was almost no joining observed at 45° C even after 15 min, whereas joining at low temperature seemed nearly normal.

Transduction experiments with strain BT 4113 showed that both the conditional lethality and the temperature sensitivity in sealing are co-transducible with the *met E* marker at high frequency (about 10%). The transduction has been performed in both directions; BT 4113 has been transduced by P1 to become temperature resistant and *met E*⁻ and the *met E*⁻ strain JW 149 has been transduced to become *met E*⁺ and temperature sensitive.

We have not yet found a mutant to be temperature sensitive in the polymerising part only, and to be conditional lethal because of that mutation. The isolation and characterisation of BT 4113 and of a similar conditional lethal *pol A* strain by Conrad and Lehman⁴ show that *E. coli* bacteria require the 5'-exonucleolytic activity of DNA polymerase I for replication and that this function of polymerase I cannot be carried out by other enzymes in the cell.

The enzyme assays were performed in Professor I. R. Lehman's laboratory. We are grateful to him and his group for their hospitality and patience, and for communicating their results to us before publication. This research was supported by the Max-Planck-Gesellschaft in Germany and by grants from the National Cancer Institute and from the National Science Foundation.

Affinity labelling the acceptor site of the peptidyl transferase centre of the *Escherichia coli* ribosome

We have identified two 50S proteins, L2 and L26-L27, in the peptidyl (P) site of the peptidyl transferase centre of *E. coli* ribosomes¹. BrAc-³H-Phe-tRNA^{Phe}, a peptidyl-tRNA affinity analogue, was shown to bind specifically to the P site and covalently react with only L2 and L26-L27. The ability of the same molecules of ribosome-bound BrAcPhe-tRNA^{Phe} to participate in dipeptide formation and covalent attachment to ribosomal proteins was the most compelling evidence for functional P site binding.

De Groot *et al.*² showed how peptidyl-tRNAs can be directed to either the P site or the aminoacyl (A) site. For example, purified Gly³-Phe-tRNA^{Phe} binds to the P site of 70S, salt-washed *E. coli* ribosomes in a cell-free system using poly (U) and either 10 mM or 30 mM Mg²⁺. This binding was not inhibited by tetracycline. The bound peptidyl-tRNA was very reactive towards puromycin. In contrast, when excess deacylated tRNA^{Phe} was added together with the peptidyl-tRNA, the distribution between the two sites was different. The greater part of the peptidyl-tRNA was now bound to the A site. This binding was inhibited by tetracycline, and puromycin reactivity of the bound peptidyl-tRNA was almost completely lost. It could be restored by adding translocation factor EF-G and GTP. Apparently, the

Table 1 Binding of BrAc-³H-Phe-tRNA

(a) Binding of BrAc-³H-Phe-tRNA to *E. coli* ribosomes (fmol)

Additions	Salt-washed ribosomes		Non-washed ribosomes

400 pmol tRNA + EF-G + GTP	—	91	65	98

tRNA^{E.coli}Phe enriched in phenylalanine acceptor activity was prepared by one fractionation of crude *E. coli* tRNA on a BD-cellulose column. This tRNA could accept about 50 pmol per A₂₆₀ of ³H-phenylalanine 60 Ci mmol⁻¹ and served also as uncharged tRNA in the specified reactions. *E. coli* ribosomes and BrAcPhe-tRNA were prepared as described previously¹¹. Salt-washed ribosomes were prepared according to Ertel *et al.*¹⁵ Binding assays were performed by the Millipore filter technique of Nirenberg and Leder¹⁶. A 20 µl binding reaction mixture contained 50 mM Tris-HCl (pH 7.6), 50 mM NH₄Cl, 3.0 A₂₆₀ of ribosomes, 20 µg of poly (U) plus magnesium acetate as indicated. Deacylated tRNA and tetracycline (0.5 mM) were added at 0° C before the addition of 240 fmol (11,000 c.p.m.) BrAc-³H-Phe-tRNA. The mixture was incubated for 30 min at 37° C. Puromycin reaction was determined as described by Leder and Bursztyn¹⁷. Where indicated EF-G (12 µg) and GTP (0.5 mM) were added after the initial incubation. The puromycin reaction in this case was measured after an additional 10 min incubation.

Table 2 Incorporation of ^3H -Phe into ribosomal proteins

	1.D	Run 1 2.D	Run 2 1.D
P site 10 mM Mg^{2+}			
Mg protein applied to gel	0.54	1.80	0.84
c.p.m. ^3H in protein L2	350 (0.076)	1,050 (0.073)	160 (0.27)
L16	75 (0.016)	246 (0.017)	180 (0.030)
L26-L27	2,900 (0.630)	9,840 (0.686)	1,130 (0.189)
P site 30 mM Mg^{2+}			
Mg protein applied to gel	—	—	1.20
c.p.m. ^3H in protein L2	—	—	60 (0.005)
L16	—	—	90 (0.007)
L26-L27	—	—	770 (0.064)
A site			
Mg protein applied to gel	0.45	1.50	0.98
c.p.m. ^3H in protein L2	130 (0.041)	420 (0.039)	170 (0.028)
L16	465 (0.145)	1,375 (0.129)	450 (0.075)
L26-L27	830 (0.260)	5,200 (0.488)	480 (0.080)

The amount of radioactivity found associated with certain ribosomal proteins was determined from the analysis of one-dimensional and two-dimensional polyacrylamide gels as described previously^{1,14}. After each ^3H c.p.m., in parentheses, is shown the corrected covalent c.p.m. ^3H incorporated per equivalent of tRNA bound per mg of protein analysed on the gel. In run 1, P site conditions actually represent 88% P site, A site represent 75% A site as determined by puromycin reactivity. In run 2, the corresponding figures are 71% P site and 75% A site.

deacylated tRNA^{Phe} could compete effectively with the peptidyl-tRNA for binding to the P site, but much less so for binding to the A site. This effect was much more pronounced at 30 mM Mg^{2+} . Watanabe and Tanaka reached similar conclusions³. AcPhe-tRNA could be directed specifically to the A site at 15 mM Mg^{2+} if the ribosomes had been preincubated with excess unfractionated deacylated tRNA.

We have used these methods to direct BrAc- ^3H -Phe-tRNA to either the P site or A site by using tRNA^{Phe} *E. coli*, and by varying the Mg^{2+} concentration. Table 1 shows that BrAc- ^3H -Phe-tRNA behaves similarly in every way to Gly₃-Phe-tRNA and AcPhe-tRNA in a poly(U)-directed cell-free system. This is true for saltwashed and unwashed ribosome preparations. BrAc- ^3H -Phe-tRNA in 10 mM Mg^{2+} and the absence of deacylated tRNA, bound almost exclusively to the P site. It was not inhibited by tetracycline. Puromycin reactivity of the bound tRNA was generally 70% or higher. In the presence of deacylated tRNA and 30 mM Mg^{2+} , however, binding seemed to be mostly to the A site. This binding was inhibited by tetracycline. Puromycin reactivity was reduced by a factor of 3 to 4. It could be restored fully by adding EF-G and GTP.

Covalent labelling reactions were done under similar conditions to those used previously¹. Unwashed ribosomes were used to facilitate comparison with earlier results and because their overall binding was generally higher than saltwashed ribosomes. Two different systems were chosen. (1) P site binding in the presence of 10 mM or 30 mM Mg^{2+} and the absence of deacylated tRNA. (2) A site binding in the presence of 30 mM Mg^{2+} and deacylated tRNA.

Subunit separation and stripping of ribosomal proteins were done as described previously¹. Most of the covalent ^3H -Phe incorporation occurred with 50S proteins. The small extent of reaction with the 30S particles will be discussed elsewhere. One-dimensional and two-dimensional acrylamide gel electrophoreses were performed to identify as unambiguously as possible any covalently labelled 50S proteins. Typical gel patterns are given in Figs 1 and 2.

Only three 50S proteins contained significant covalently incorporated ^3H -Phe. These were L2, L26-L27 and L16. Table 2 shows that the pattern of radioactive incorporation into the three proteins was markedly affected by the conditions used. The good agreement between parallel one-dimensional and two-dimensional analyses on the same sample encourages quantitative comparisons. The P site

Fig. 1 BrAc- ^3H -Phe-tRNA-reacted 70S ribosomes were separated into subunits and the ribosomal proteins were analysed by one-dimensional gel electrophoresis as described earlier¹⁴. Labelling patterns from one-dimensional gels are shown for 50S proteins from: (a) P site reaction mixture; (b) A site reaction mixture; (c) A site reaction mixture in the presence of 0.5 mM tetracycline; (d) A site reaction mixture in the presence of 1 mM puromycin. Total protein put on the gel was 0.54 mg in (a), 0.45 in (b), 0.48 in (c), and 0.30 mg in (d). Labelling reactions contained 20 mg of ribosomes with 24 pmol (1.1×10^6 c.p.m.) of BrAc- ^3H -Phe-tRNA and 2 mg of poly (U) in the presence of 10 mM Mg^{2+} for P site binding, and 30 mM Mg^{2+} and 1 mg of uncharged tRNA for A site binding. The concentrations of Tris buffer and NH_4Cl were the same as given in Table 1. After incubation for 30 min at 37°C, 20 μl aliquots were taken and checked for binding and puromycin reactivity in the presence and absence of EF-G and GTP. Where indicated either tetracycline (0.5 mM) or puromycin (1 mM) were added to the A site reaction mixtures before the addition of BrAc- ^3H -Phe-tRNA. It was found that 8,520 c.p.m. of BrAc- ^3H -Phe-tRNA were bound to a sample of 0.2 mg ribosomes from the P site reaction mixture as measured by Millipore binding assay¹⁸. 7,450 c.p.m. (88%) of this sample could react with puromycin. The binding to an equivalent amount of ribosomes from the A site reaction mixture was 7,130 c.p.m. of which only 1,760 c.p.m. (25%) were puromycin reactive.

results are quite comparable to previous results¹, except that L2 is less reactive with this particular ribosome preparation. Similar variations have been seen before. For the same preparation of ribosomes and BrAcPhe-tRNA, however, the ratio of L2:L26-L27 in a P site experiment is very reproducible. The A site conditions with the same preparation gave a striking increase in reaction with protein L16 and a decrease in reaction with L2 and L26-L27. The L16 reaction is not simply due to the presence of 30 mM Mg²⁺ as shown in Table 2. In the absence of deacylated tRNA, even with 30 mM Mg²⁺, the binding of BrAcPhe-tRNA is mostly to the P site (Table 1). Only when excess deacylated tRNA is added does BrAcPhe-tRNA move to the A site with a concomitant rise in the L16 reaction.

One reason why the pattern of BrAcPhe-tRNA reactivity shown in Table 2 is complex is that P site and A site conditions still lead to binding to both sites. If puromycin reactivity is used as a measure of true P site binding, P site conditions still allow 12–29% A site binding while A site conditions allow 25% P site binding. These cross-contaminating binding modes can be corrected for by the appropriate simple algebraic manipulation. This permits calculation of the relative efficiencies of reaction of a pure

inhibition of the binding of the aminoacyl end of BrAcPhe-tRNA to the A site would explain the diminished L16 reaction.

Our assignment of L16 as an A site protein may clarify other recent affinity labelling studies. Several lines of evidence^{6–9} indicate that chloramphenicol and puromycin compete for the same binding site on the 50S particle, the A site. Sonnenberg *et al.*¹⁰ observed a covalent reaction of the chloramphenicol analogue, bromamphenicol, with two proteins, L2 and L27. Pongs *et al.*¹¹ found that another analogue, moniodoamphenicol, reacted covalently with a single 50S protein, L16. Reconstitution experiments demonstrated that L16 was required for chloramphenicol binding¹². One explanation for this discrepancy is the known occurrence of two ribosomal binding sites for chloramphenicol¹³. The iodoamphenicol results^{11,12}, however, are consistent with our identification of L16 as exclusively an A site protein. L2 L26-L27 can react with BrAc-³H-Phe-tRNA bound at both the A and P sites. This is consistent with the bromamphenicol results¹⁰. It appears that proteins L16, L2, L26-L27 are all located at the peptidyl transferase centre and are probably quite close to each other.

This work was supported by grants from the US Public Health Service and the US National Science Foundation. H. O. received an NIH predoctoral fellowship. We thank C. C. Lee and Nancy Hsiung for salt-washed ribosomes and EF-G factor, and Alice Beekman and Elaine Lin for technical assistance.

Fig. 2 50S protein samples from reaction mixtures (a) and (b) (see Fig. 1), were analysed by two-dimensional gel electrophoresis as described previously¹.

A or P site bound species with each of the three reactive 50S proteins. Such calculations show that virtually all the small L16 reactivity seen under P site conditions can be accounted for by contaminating A site-bound material. Therefore, L16 is definitely an A site protein. It is vastly more reactive when BrAcPhe-tRNA is bound in this site than in the P site.

L26-L27 and L2 appear to be P site proteins. The reactive sites of L26-L27 and L2 may be reached from both A and P site bound BrAcPhe-tRNA, but the higher efficiency from the latter suggests that they are much closer to the P site or the reaction is sterically more favourable.

Figure 1 shows the effect of 0.5 mM tetracycline and 1 mM puromycin on the pattern of covalent labelling under A site conditions. Tetracycline, a known inhibitor of A site binding⁴ diminished the reaction of L16 by a factor of 2. A much smaller effect was seen with L2 and L26-L27. Puromycin which releases any P site-bound peptidyl-tRNA reduced the reaction with L16, L26-L27 and L2. The marked reduction of L16 reaction needs to be explained since 1 mM puromycin is not likely to release any A site-bound peptidyl-tRNA. Lessard and Pestka⁵ have shown that puromycin competition appreciably reduced the binding of aminoacyl oligonucleotides to ribosomes. A similar

Identification of a population of mouse leukocytes using wheat germ agglutinin

A GROUP of proteins occurring commonly in plant extracts have the property of agglutinating blood cells by intercellular linkage of surface carbohydrate groups^{1,2}. These proteins, usually called lectins, are often able to distinguish cell types by preferentially agglutinating cells which express a particular membrane glycoprotein³. We report here that one lectin, wheat germ agglutinin (WGA)⁴, is able to distinguish a group of mouse leukocytes carrying neither immunoglobulin nor T-cell surface markers.

Cells teased from spleens of normal BALB/c mice were washed with Eagle's minimum essential medium containing 10% foetal bovine serum. Suspensions containing 10^7 cells ml^{-1} were treated with increasing concentrations of fluorescein-conjugated WGA and the number of labelled cells counted immediately using a Leitz Ortholux ultraviolet microscope with incident illumination. The results are shown in Fig 1. A consistent proportion of spleen cells was found to be strongly labelled at WGA concentrations of between 20 and $100 \mu\text{g ml}^{-1}$. Staining was eliminated either by previous addition of 0.025 M N-acetyl glucosamine (NAG) to the cell suspension, or by subsequent washing of the cells with Eagle's medium containing 0.05 M NAG. In contrast, washing with 0.1 M NAG had no effect upon spleen cells previously labelled with another fluorescein-conjugated lectin, concanavalin A.

Fig. 1 Proportion of mouse spleen cells labelled with increasing concentrations of fluorescein-conjugated WGA.

Table 1 shows the proportions of cells from other mouse lymphatic tissues having receptors for WGA.

The morphology of this cell population was investigated by electron microscopy. Mouse spleen cells were incubated for 5 min at 4°C with a $250 \mu\text{g ml}^{-1}$ concentration of WGA/horseradish peroxidase conjugate⁵ in phosphate buffered saline. The cells were then washed, fixed and treated with diaminobenzidine and osmium tetroxide before embedding and sectioning. Cells with heavy surface labelling were characterised as monocytes and polymorphonuclears, many with peroxidase-positive cytoplasmic granules. Lymphocytes and plasma cells showed very weak or no staining. Further details of these experiments will be published elsewhere.

To see whether cells with abundant WGA receptors carried immunoglobulin or T-cell markers the following experiment was performed. Aliquots of 2×10^6 cells were treated with either 100 μl of a 1:4 dilution of rabbit anti-mouse immunoglobulin serum or with 100 μl of rabbit anti-mouse brain serum, sequentially absorbed with erythrocytes, liver and B-spleen (spleen from irradiated animals repopulated with bone marrow cells) to render it specific for T lymphocytes⁶. All cells were subsequently

Table 1 Percentage of leukocytes in mouse tissues labelled with WGA ($50 \mu\text{g ml}^{-1}$)

Spleen	Lymph node	Thymus	Blood	Bone marrow
12	<0.5	<0.5	7	72

stained with rhodamine B-conjugated goat anti-rabbit immunoglobulin serum. The cells were then washed thrice and labelled with 100 μl of a $50 \mu\text{g ml}^{-1}$ solution of fluorescein-conjugated WGA. Of the 12% of cells in each sample labelled with wheat germ agglutinin, none showed rhodamine fluorescence indicative of either immunoglobulin or T-cell surface markers. Conversely, T cells were not stained with WGA. Although WGA did not stain immunoglobulin-bearing cells under these conditions, at lectin concentrations greater than $100 \mu\text{g ml}^{-1}$, both immunoglobulin-bearing cells and erythrocytes showed weak fluorescence.

This is consistent with the findings of Schnebli and Dukor⁷ that mouse B cells are agglutinated more strongly than cortisone-resistant thymocytes at low concentrations of WGA. Wheat germ agglutinin has also been shown to agglutinate certain malignant cells⁸. Our results show that mouse leukocytes in lymphoid organs and blood which have abundant binding sites for WGA are essentially of myeloid morphology and do not carry the surface markers of B or T lymphocytes.

We thank Dr A. K. Allen for his gift of purified WGA, Dr C. Maino for a number of other lectins used in this study and Miss M. Gyöngyösy for rabbit anti-mouse brain serum. This work was supported by the Medical Research Council.

Note added in proof: In contrast with resting mouse lymphocytes, lymph node cells transformed with phytohaemagglutinin or concanavalin A were found to bind WGA to a moderate degree.

Adjuvant activity in delayed hypersensitivity of the peptidic part of bacterial peptidoglycans

It is generally accepted that the presence of killed mycobacteria in complete Freund's adjuvant is necessary to induce a typical delayed hypersensitivity to soluble antigens¹ and attempts have been made to isolate the active component. The preparations obtained initially were of a peptidogly-

There is a pressing need to explore the area of interaction between engineering principles and biological systems — a research field which until recently has been neglected. The intricacies of biotechnology embrace the full range of present-day chemical engineering and the biological sciences. Their interaction has not only brought about a great reduction in the cost of producing some foods and life-saving drugs, but has advanced new concepts to improve the understanding of the engineering principles involved in the operation of processes like air sterilization, separation of biological molecules, enzyme systems, continuous culture, handling of biological fluids, oxygen transfer in large-scale fermentation systems, etc. The problem is to find a realistic solution bridging these two distinct areas; this requires the breaking down of communication barriers between biological scientists and engineers and the active interchange of information. The series *Advances in Biochemical Engineering* is designed toward this end.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:

Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes**, M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage**, D. P. Tihansky. **Effects of Red Mud on Marine Animals**, R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn**, M. Karpuzcu.

Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. book reviews

Quality quantified

Social Stratification in Science. By Jonathan R. Cole and Stephen Cole. Pp. xiv+283. (University of Chicago: Chicago and London, 1973). £5.65.

SINCE 1967 the Coles have been addressing themselves to a set of interesting problems concerning the internal social organisation of science, using as principal tool the *Science Citation Index*. The number of citations received is taken to be a measure of the quality of scientific work. Those who disdainfully dismiss this way of measuring quality should read the discussion of its reliability and validity in chapter 2 of the book. Despite the admitted drawbacks—notably the fact that important discoveries may become accepted to the extent that the original papers stop being cited—it emerges from the scrutiny as a reasonable indicator.

The Coles' major concern is the degree to which the reward system of science operates by universalistic criteria. How far do inequalities in the rewards received reflect quality of work, rather than particular attributes like sex or race or being related to the right people? Is the homage which conventional rhetoric pays to universalistic ideals better matched in practice by science than by other social institutions? The answer is reassuring. Science—which here means mostly American physics—emerges in a favourable light. For receipt of honorary awards, for visibility and for appointments in prestigious university departments, quality of research is found to be a key determinant.

Women are not much discriminated against—once they are over the Ph.D. hurdle. The same limitation effectively removes from the field of study the question of discrimination against blacks, because they receive so few Ph.Ds (less than one per cent of those given in science). The restricted scope of the Coles' study is exposed by their revealing use of the expression "social origins" to refer to the rank of the scientist's doctoral department (page 117). It is only for those who have got inside the system that its inequalities can be seen to be equitably distributed.

Is there a serious departure from universalism in what R. K. Merton has called "the Matthew effect" ("For unto every one that hath shall be given"—Gospel according to St Matthew)? The Coles test the consequences of such an

assumption for the diffusion of knowledge and conclude that the effect is rarely important. Controlling for assessed quality at time 2, the assessed quality of papers at time 1 is only slightly influenced by the reputation already achieved by their authors.

The Coles also test what they call "the Ortega hypothesis", after an assertion by Ortega y Gasset that the many scientists who are of no more than mediocre quality nevertheless contribute in a major way to scientific progress. The work that physicists use in their best papers, as indicated by the references they cite, is itself found to be produced largely by elite physicists. This does not support the hypothesis and leads to the suggestion, which may antagonise some readers, that the number of active physicists could be cut substantially without crippling progress.

Science as studied by the Coles is defined in a narrow way. Only the publication of research papers counts; even review articles are excluded. Teaching students or administering research establishments or advising governments is "unproductive"; so is improving the productivity of industry. The "quality" of a company or government agency is determined by its commitment to basic research (page 43). Social responsibility in science is outside this impregnable circle of definitions—so far outside that the idea that "rather than society influencing science, science influences society" is described as one that "some of the more polemical historians of science have gone so far as to argue" (page 14).

The most immediate danger arising from work like that described in this book is that statistical measures adequate for fair-sized samples may be misapplied to individual cases. Within a few pages of a warning about this (page 31), the authors themselves are teetering on the brink. In general, however, they remain clearly aware of the limitations of their approach and they use their tools with care as well as ingenuity. They have done a useful exercise in the art of the possible. Like it or not, citation counts will doubtless continue to be used as well as misused, and the Coles' work itself is likely to be plentifully cited. The smokescreen of sociological jargon in their book is refreshingly thin and the style is lucid, considering the high density of correlation and regression coefficients.

F. R. JEVONS

Ignorance of interferon

Interferon: Theory and Applications. By V. D. Solov'ev and T. A. Bektemirov. Translated from Russian by Basil Haigh. Pp. xvii+304. (Plenum: London and New York, 1974.) \$30.

THERE have been several international meetings on interferon during the past few years, but unfortunately Russian workers have not been able to attend any of them—often having to withdraw at the last moment. Since the Soviet Union has also had few visitors from the West, this has led to the isolation of the Russian workers and the effects of this isolation are only too apparent in this present book.

The book claims, in its foreword, "to give a systematic account of the existing information on interferon obtained both from the extensive literature, and from the authors' own observations made over a period of several years..." The book falls sadly short in its first aim—that is to give a systematic account of the existing information on interferon. First of all, it is out of date. This is obvious as soon as one looks at the extensive list of references given at the end of the volume. The first hundred and ninety refer to Russian papers published up to 1967, the next four hundred to papers by non-Russian authors (only three being later than 1967), while the final hundred are made up of more recent Russian publications and Western papers, but only twenty odd are dated 1970 or later. This is presumably because the Russian text was published in 1970, but it is a pity that the text was not updated before translation. The book shows its age in other ways too—the account of interferon purification is nearly ten years old and data presented on the molecular weight and amino acid composition of interferon is quite incorrect. The translational-inhibiting protein theory of Marcus and Salb is restated although it was abandoned years ago. Isaacs's theory that interferon induction is due to 'foreign' nucleic acid is described, although Isaacs himself later withdrew it. Nagano's inhibitory factor is described as an interferon, despite Fantes's (1966) careful analysis of the results, showing that the inhibitory factor is almost certainly a polysaccharide. There is no account of the interferon standardisation meeting in London in 1969, nor of the development of

reference research standards for interferon.

The other aim of the book is to describe Russian work hitherto unpublished in English. This falls into two main areas—measurement of interferon production by different viruses in a variety of cells and the use of interferon in man. The interferon production experiments are presented at great length and quite uncritically, and their total effect is merely to demonstrate that many factors are responsible for the control of interferon formation. The work on the role of interferon in infection and its use in clinical trials in the Soviet Union is more interesting, and is the only justification for translating the book into English. I am much less competent to assess this data, which seems to me to be interpreted rather optimistically.

In summary, this is not a book to purchase or to recommend for library purchase, unless one has an interest in learning of Russian work on the role of interferon in natural infections.

D. C. BURKE

Technology of insect flight

Insects in Flight. By Werner Nachtigall. Translated by Harold Oldroyd, Roger H. Abbott, and Marguerite Biederman-Thorson. Pp. 150; 32 plates. (Allen and Unwin: London, May 1974.) £5.50.

MUCH that is new has been learned about insect flight in the past fifteen years, and Werner Nachtigall has been one of the most productive workers in this field. He has published a long series of papers in German which provide a detailed analysis of wing movements in the blowfly in free flight, by the use of highly sophisticated experimental methods. A few years ago he conceived the idea of writing a book about the flight of insects which would illustrate the thrills and frustrations of research, and form a tribute to the beauty and ingenuity of the technology of insect flight. The book has now been translated into English and appears in well printed and beautifully illustrated form.

The author writes for students and teachers with interests in technology and engineering, for those engaged in piloting gliders or powered aircraft, and indeed for the general reader. He is wholly successful in putting across the biophysics of the flying insect—though he expects his readers to concentrate! He describes the aerodynamics of flight in terms of instantaneous linear forces and avoids the more demanding aerodynamical approach: bound vortices and the generation of the aerodynamic cross force are passed over and Reynolds numbers appear only in a single caption. The story is varied and enlivened

by literary excerpts; by excursions into locust plagues; the rôle of flight in the life of the honey bee and other insects; insect migration; fuel, temperature and sensors in flight; the technological rivalry between sonar hunting bats and acoustically equipped moths; the contrasts and comparisons of insect and human flight—and much more besides.

The author has a gift for vivid depiction: "to a fly, a cine film must look like a lantern lecture, with long dark pauses in between the slides". The book is admirably translated but in at least one place the popular error in translating 'Schmetterling' leads to the description of the hawk-moth *Celerio* as a 'nocturnal butterfly'.

V. B. WIGGLESWORTH

Exploring evolution

Evolution in the Microbial World. (24th Symposium of the Society for General Microbiology, held at Imperial College London, April 1974.) Edited by M. J. Carlike and J. J. Skehel. Pp. x+430. (Cambridge University: London, April 1974.) £7.50; \$22.50.

THIS volume, in the words of the editors, is believed to represent the first account devoted to the topic of microbial evolution. Such an embracing title would be expected to cover a very wide range of topics indeed and, although there is a great deal of information in this book which bears on the evolution of microbes, it would be useful to indicate what the book does not contain. It does not include, and does not claim to cover, aspects of comparative microbial anatomy nor a discussion of phylogeny based on such evidence. In fact, no indication is given of the wide range of structural diversity found in microbes. Similarly, there is little reference to the possible route of evolution of major groups of microorganisms.

Instead, the emphasis of the text is placed, not upon the apparent path of evolution, but on those special properties of microorganisms which make them such favourable experimental material for exploring the mechanisms of evolution. The sequence of chapters is essentially hierarchical, starting with problems of taxonomy and phylogeny and leading to essays dealing with mutation, recombination and selection. Successive chapters deal with the evolution of molecules, with organisms, and with energy-yielding processes as well as with the evolution of a biological association (symbiosis).

The first chapter (by P. H. A. Sneath) is a lucid summary of current strategies for constructing the phylogenetic relationships of microbes and includes a full discussion of taxonomic principles. The following four chapters deal

with aspects of the evolutionary mechanism. Drake, for example, discusses the role of mutation in evolution and the measurement of mutation rates. Richmond and Wiedeman discuss plasmids in relation to bacterial evolution. Although the significance of plasmid-borne resistance factors is stressed, the basic theme of the essay is recombination mechanisms involving plasmids and their possible similarities to recombination in phages. The wider role of recombination in regulating breeding systems and the formation of new species is considered by Esser. Kubitschek summarises some of the material concerning selection pressures on bacteria grown in the environment of a chemostat.

One of the most powerful analytical techniques yet applied to the study of phylogenetic relationships is the technique of doublet analysis, by estimating the frequency of nearest-neighbour base sequences in DNA. Subak-Sharpe *et al.* give a full account of their studies on the reliability of the technique as applied to the DNA of bacteria and viruses. Experimental approaches to the problems of the evolution of enzymes and the way in which specificity of action is related to enzyme activity are discussed by Hartley. A similar theme is reiterated by Clarke, who summarises her work on the nature of adaptation of bacteria exposed to novel substrates in terms of the evolution of the requisite enzymes needed to utilise the substrate.

Three chapters are devoted to the evolution of energy-yielding processes: photosynthesis (Stanier), sulphur metabolism (Peck) and nitrogen fixation (Postgate). These essays do not merely summarise the salient features of the relevant biochemistry but also discuss the possible origins and evolution of such mechanisms in prokaryotes and eukaryotes. The remaining chapters are devoted to patterns of organisation and association among microbes. As examples of the evolution of organisms two divergent levels of organisation are considered: viruses (Joklik, Skehel) and the haemoflagellate *Trypanosoma* (Baker). The nature of symbiosis and mutualism are discussed by Lewis. Finally, Ponnamburama and Gabel discuss the possible condition of the prebiotic milieu in relation to the formation of complex molecules and the emergence of life.

As a summary of current thinking on problems of evolution among microbes this volume contains much to interest the reader. More importantly, the essays included succeed in demonstrating the feasibility of using microorganisms to unravel some basic aspects of the evolutionary mechanism.

I. D. J. BURDETT

Mouths of waders

Feeding and the Feeding Apparatus in Waders: A Study of Anatomy and Adaptations in the Charadrii. By P. J. K. Burton. Pp. 150. (British Museum (Natural History): London, 1974.) £3.50.

DURING recent decades workers may have been somewhat deterred from studying the Charadriiformes by the documentation provided in "Witherby" and by the detailed knowledge possessed by amateur ornithologists but there is now evidence of a widespread resurgence of interest. This present book, a quite admirable discussion of functional morphology, considers charadrioid bill structure and oral musculature from a variety of viewpoints.

The information on overt feeding behaviour which is contained in the opening sections includes many original observations alongside a useful panoramic survey culled from the world literature. I was particularly interested in the statements about *Pluvialis squatarola* as they contrast with the data obtained by Dr G. A. Parker and myself. The remainder of the book deals in detail with the degrees of rhynchokinesis, and the variations in bill, tongue and hyoid structure, which are associated with different methods of feeding. In particular Dr Burton emphasises that highly rhynchokinetic upper jaws have probably evolved independently in at least seven lines of Charadriodea. The interdependence of modifications for a particular method of feeding is certainly widely known but this account provides many further examples.

Written with great clarity, the book will be a valuable addition to specialist libraries and encourage a continuing synthesis of morphology and ethology. One can only express passing regret that, although the work was initially supported by the Scientific Research in Schools Committee of the Royal Society, the author gave up his teaching post to complete it. Surely this was not the intention behind the committee? Britain needs able and enthusiastic teachers.

RONALD PEARSON

Seabed skeletons

Recent Sedimentary Carbonates. Part 1: Marine Carbonates. By J. D. Milliman. Pp. xv + 375 + 39 plates. (Springer-Verlag: Berlin and New York, 1974.) DM66; \$27.10.

This book is an excellent attempt to synthesise present knowledge about calcium carbonate in the marine environment, its composition, sedimentation and diagenesis. It is apparent that Milliman has used his experience

gained in researches over a broad spectrum of the field of Recent sediments and also a wealth of data from the latest literature to put together this comprehensive textbook, which will appeal to final year undergraduates, research students and established carbonate sedimentologists.

The book is divided into four parts: introduction, carbonate components, marine carbonate sedimentation and carbonate diagenesis. Part 1 includes a valuable introduction to the techniques employed in the analysis of such parameters as texture, petrography, mineralogy and elemental and stable isotope composition. This practical aspect is supplemented by the two appendices, which, although very brief, do establish a starting point for the identification, in thin section and under reflected light, of the major carbonate components of Recent marine sediments. The major portion (part 2) of the book synthesises an extensive literature on the ecology, calcification, petrography and composition of various skeletal and non-skeletal carbonate components. This section includes many quantitative data on topics including growth rates, mineralogies, minor trace element and stable isotope distributions which will serve as a useful reference for marine sedimentologists. The third part of the book deals with the distribution of marine carbonates. Milliman does not concentrate on a few shallow tropical sea environments, which is sensible, for this particular setting is treated in considerable depth in other recent books, but instead he gives equal attention to the shallow seas, shelf waters and the deep sea. The final part traces the diagenetic alteration of carbonates within the marine environment through degradation, cementation and dolomitisation.

The style is clear and the presentation straightforward. One of the most useful and original features of the book is the plentiful tabulation of quantitative and descriptive data from a wide variety of sources. In this way such information as chemical composition of skeletons, distribution of major planktonic foraminifera species, and depositional environments and chemical properties of modern marine dolomites are succinctly expressed for easy comparison and assimilation. The photographs are arranged in plates which on the whole are clear and appropriate, though for ease of reading I would have preferred photographs interspersed with the text. Several photographs are too small to serve much value and the general standard of plates is not the excellent quality one has come to expect from Springer-Verlag geological publications.

It is inevitable that this book will be compared with the recent comprehensive textbook on carbonate sediments and their diagenesis by Bathurst.

Though the themes of the two books are similar the contents overlap to a relatively small degree (as an indication only 375 references are common to the two books which have a total of over 2,000 references). This partly results from the different experiences and approaches of the two authors and partly from the inclusion in Milliman's book of many references to works published during the past three years.

T. P. SCOFFIN

Explaining solid state

Electronic Properties of Crystalline Solids: An Introduction to Fundamentals. By Richard H. Bube. Pp. xiii + 524. (Academic: New York and London, January 1974.) \$35; £16.80.

THE solid state physics contained in this book is, at first sight, fairly traditional, both as regards subject matter and treatment. On closer examination, however, it becomes apparent that Dr Bube has made a useful and significant addition to the range of text books now available to third year undergraduate and first year postgraduate students specialising in solid state physics. The author clearly intended to explain the main elements of the subject within a sound mathematical framework. He wisely resisted the temptation to discuss many aspects superficially and instead concentrated on taking a few examples of solid state phenomenon and treating them in some depth. Reviewers who judge a book by what has been left out may, therefore, find the choice of material not to their liking; I, for example, would like to have seen a little more on metallic alloys. But these are matters for personal judgment and should not be allowed to detract from a well written and beautifully produced textbook.

There are twelve chapters in the book which cover the three principal themes of solid state physics. The first three chapters focus attention on wave theory and the application of quantum mechanics to simple systems. The examples here were carefully chosen with an eye to later chapters. The next three chapters develop the band theory of solids taking as a starting point the free electron (Hartree) model. The reader will, if he works through these chapters and the excellent range of problems associated with each of them, gain a good understanding of basic band theory. I was particularly pleased to see a discussion of 'bands' versus 'bonds' and that the concept of electronegativity is at last appearing in solid state physics textbooks. The role of localised energy levels leading to the characteristic behaviour of semiconductors is described, a shade too briefly perhaps, in chapter 9. The remainder of the

book deals with the motion and excitation of carriers by external fields and includes a particularly helpful discussion of photoelectron effects. The book is well indexed, remarkably free from typographical errors and will, I feel sure, be a useful textbook for a variety of students (and their seniors) for the next few years.

J. E. ENDERBY

Lichens

The Lichens. Edited by Vernon Ahmadjian and Mason E. Hale. Pp. xiv+697. (Academic: New York and London, January 1974.) \$35; £16.80.

ABOUT one fifth to one quarter of all described species of fungi are lichenised, but very few books have been written about them. Indeed, this is the first large and comprehensive work of advanced scholarship in the English language about lichens since the classic monograph of A. L. Smith in 1921. Furthermore, since so few botanists specialise in these plants, there is unlikely to be another book of this type for some time to come. It is, therefore, something of a milestone in the development of the subject.

There are 23 authors contributing 19 chapters and 3 appendices, covering a wide range of topics including morphology, taxonomy, reproduction, physiology, ecology, secondary metabolic products and symbiont interactions. Inevitably, there are some gaps. In the preface, the editors say that chemotaxonomy is one of the main present day areas of research in lichens, yet the book has no chapter devoted to this richly controversial topic: indeed, it gets but a passing mention in one appendix, and is not cited at all in the index.

Unevenness in quality is to be expected in all multiauthor works, and this is no exception. Although the editors have been very thorough and painstaking—so that errors and unclear passages are rare—it is a pity that they did not persuade authors to be more interpretive in their approach. Too many contributors are content to give meticulous accounts of published observations without following up with an incisive section which says, in effect, "... now what all this means is ... so that the problems which now require solution are ...".

Hence, the memorable parts of this book are the handful of chapters in which the authors develop a critical, personal synthesis of their views. Poelt's critique of the systematic value of morphological characters is particularly good. The account by Tuominen and Jaakola of the accumulation of mineral elements and radionuclides is

not only a valuable review of widely scattered literature, but it also sets a refreshingly high standard of rigour in discussing physiological topics. Brodo's excellent chapter on substrate ecology is profoundly thoughtful: at long last, here is a lichen ecologist who can write, quite simply, "I think the terms 'nitrophilous' and 'calciphilous' imply a knowledge of the requirements of lichens that we do not yet have".

For some students, the book will be hard going for it lacks an introductory chapter to set the scene. More acutely, it needs a concluding chapter to draw together the diverse strands of the individual contributions. Here would have been a chance for the editors to paint the broad canvas of the nature of the interactions between the symbionts; or to integrate the different themes of the chapters on substrate ecology, resistance to extreme environments, and mineral accumulation; or point out the gaps which, in the preface, they say exist.

The price puts this book beyond the reach of almost all students and academics, but I think it is essential for all botanical libraries. Although it does not achieve the same classic status as A. L. Smith's 1921 monograph, it nevertheless contains some important, substantial and valuable contributions about lichens which are not available elsewhere. Academic Press may be able to blame inflation for the price, but they cannot blame anyone but themselves for a subject index which is so skimpy, has so very many omissions and is so poorly organised as to be nearly worthless.

D. C. SMITH

Blue-eyed Negroes

Light-Eyed Negroes and the Klein-Waardenburg Syndrome. By Jenni Soussi Tsafirir. Pp. viii+153. 20 plates. (Macmillan: London and Basingstoke, March 1974.) £7.50.

THIS little book describes and discusses 18 non-Caucasian families ascertained by eye colour, where one or more members had Waardenburg's syndrome, and 10 families where one or more members had unilateral or bilateral blue or light green eyes, or heterochromia iridis.

Much of the book is devoted to discussion of Waardenburg's syndrome and, though the clinical descriptions of manifestations of the disorder are excellent, there is much repetition and nothing new is added to knowledge or understanding of an autosomal dominant trait which is relatively common and has been reported in many races. The families where there was only hypochromia of iris, which resulted in blue or greenish eye colours, or

where there was heterochromia inherited as a dominant trait are of much greater interest, and this is the best account so far given of these phenomena in Africans.

I feel that all the information in the book could have been presented in a short paper, or possibly in two papers, one on Waardenburg's syndrome in Africans and one on the other group of subjects. As it stands the book reads as if it was a condensation of an excellent thesis, although such an origin is not mentioned. Presumably the very high cost of this book is in part due to the nine pages of excellent colour photographs.

ALAN C. STEVENSON

African medicine

La Pharmacopée Sénégalaise Traditionnelle: Plantes Médicinales et Toxiques. By J. Kerharo, with J. G. Adam. Pp. 1011. (Editions Vigot Frères: Paris, 1974.) 370 francs.

PROFESSOR Kerharo is well known for his previous studies on the indigenous medicine and medicinal plants of the Ivory Coast and Upper Volta. During the past 15 years he has carried out similar, very detailed investigations in Senegal and his findings are now made available in this monumental work. The first part (about 75 pages) fills in the historical, (phyto) geographical, and ethnic background. It also discusses the religious and magical concepts underlying the various indigenous systems of medicine as well as the more positive aspects like diagnosis, pharmaceutical operations, and how medicines are dispensed and administered.

The second and main part of the book (about 700 pages) comprises detailed, individual monographs on about 555 plants. These monographs are divided into sections dealing with synonyms, vernacular names, distinguishing botanical features, habitat, folk-medicinal uses, chemistry and pharmacology. The chemical and pharmacological sections are extended and up to date accounts which summarise data from more than 2,200 references (closing date, May 1973). They are a particularly important feature of the book and extend its usefulness and value far beyond the confines of Senegal, since much of the flora of that country occurs in other parts of West Africa and elsewhere.

The third part (about 200 pages) comprises the bibliography and the various indices. Professor Kerharo's book provides a welcome complement to Watt and Breyer-Brandwijk's *Medicinal and Poisonous Plants of Southern and Eastern Africa*.

Classified Advertisements

CONDITIONS. All advertisements will only be accepted on the condition that the advertiser warrants that the advertisements do not in any way contravene the provisions of the Trade Descriptions Act 1968 and the Race Relations Act 1968. The Publisher also reserves the right to refuse, amend, withdraw or otherwise deal with all advertisements submitted to him at his absolute discretion and without explanation. All advertisements must comply with the British Code of Advertising Practice.

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes.

Semi-displayed £3.60 per 10 mm. Minimum £7.20, each additional 2 mm 72p. Full page £230.00. Half page across £125.00. 30p is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, London, WC2A 2ED. Telephone: 01-242 6264. Telegrams: Textualist, London, W.C.2.

APPOINTMENTS VACANT
**UNIVERSITY OF ALBERTA
DEPARTMENT OF ENTOMOLOGY**

Applications are invited for the position of ASSISTANT PROFESSOR, effective April 1, 1975. Qualifications are Ph.D. with postdoctoral experience in insect physiology and interest in aspects of this field applicable to agricultural or forest entomology. Duties include teaching courses in general or applied entomology and insect physiology, the development and direction of a research program and supervision of graduate students in insect physiology and in application of some aspect of physiology to agricultural or forest entomology. Maximum starting salary \$14,043.

Please send full curriculum vitae and names of 3 referees by October 31, 1974 to: Dr George E. Ball, Chairman, Department of Entomology, 260 Agriculture Building, University of Alberta, Edmonton, Alberta T6G 2E3. (297)

**THE UNIVERSITY OF
NEWCASTLE UPON TYNE
CHAIR OF GEOGRAPHY**

Applications are invited for the post of Professor of Geography. The vacancy arises as a result of the resignation from September 30, 1974, of Professor J. W. House, to take up the Halford Mackinder Professorship of Geography at the University of Oxford. Salary in accordance with the Professorial Scale (£5,973 by £96 to £6,069 by £195 to £6,849 per annum).

Further particulars may be obtained from the Registrar, the University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, should be submitted not later than September 14, 1974. (495)

**LINCOLN UNIVERSITY
COLLEGE OF AGRICULTURE
New Zealand
CHAIR IN AGRICULTURAL
MICROBIOLOGY**

The Council of Lincoln College, a University College of Agriculture located in Canterbury, New Zealand, invites applications for appointment to the Chair in the Agricultural Microbiology at this University College.

The successful applicant will be Head of the Department of Microbiology, which is responsible for a major teaching programme from Diploma to Post Graduate level, and which has active research and advisory interests. The present establishment includes 1 Reader, 2 Senior Lecturers, 1 Lecturer, 1 Demonstrator and 3 Technicians.

Applicants should hold an advanced university degree in an appropriate field and it would be expected that they would have had experience in teaching and/or research.

The successful applicant will be appointed to the position within the existing range of professorial salaries, the commencing salary being in accordance with qualifications and experience within the range of \$NZ15,111 to \$NZ19,233 per annum.

Expenses of appointment reimbursed up to specified limits. The appointee will be eligible to join the New Zealand Government Superannuation fund, or if eligible, he may elect to continue for a limited period existing F.S.S.U. policies.

Apply in writing for Conditions of Appointment obtainable from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, Lincoln College Canterbury, New Zealand. Applications close on **October 15, 1974.** (582)

Ecological and Biological Aspects of Pollution Control

£7,000-£8,000+

This is a key appointment in the Central Unit on Environmental Pollution which is the nucleus of the Government's anti-pollution activities. It is responsible for identifying and investigating problem areas, often on an international scale, for formulating appropriate policies and for co-ordinating the work of Government Departments in this field.

As a senior member of this group, you will provide biological and ecological advice over a wide range of these activities. Your particular responsibility will be the marine, freshwater and terrestrial fields, where you will initiate and control detailed studies on specific problems. You will also represent the Department of the Environment on Government and international committees and working parties.

You must hold a degree or equivalent in a biological science. While a background in marine or freshwater ecology would be of particular interest, other fields could also be relevant, and experience of pollution problems including national and international liaison duties would be an advantage.

Starting salary for this London-based appointment will be within the range quoted above.

Further details and an application form (to be returned by 2nd September 1974) may be obtained by writing to the Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB or by telephoning BASINGSTOKE 29222 ext 500 or LONDON 01-839 1992 (24 hour answering service). Please quote S/8710/1.

DORSET AREA HEALTH AUTHORITY EAST DORSET HEALTH DISTRICT

A vacancy exists for a

BASIC GRADE BIOCHEMIST

In the Group Biochemistry Service. Applicants should have a 1st or 2nd Class Hons. Degree in Chemistry or Biochemistry. Experience in Clinical Biochemistry would be an advantage.

Terms and Conditions as laid down in Whitley Council Regulation PTA/A.

Application forms from Employment Officer, District Administrative Offices, Royal Victoria Hospital, Shelley Road, Boscombe, BOURNEMOUTH, Dorset BH1 4HX giving two referees.

Enquiries about Post to Dr. J. H. Johnstone, Consultant Biochemist, Department of Biochemistry, Royal Victoria Hospital, Boscombe, BOURNEMOUTH, Dorset BH1 4JG.

*Closing date: August 31, 1974.

(612)

**Tropical Products Institute
London**

Meat Technologist

■ Laboratory investigations of meat quality ■ Applied technology in handling, preserving and processing ■ Abattoir improvement in tropics ■ Liaison with tropical agriculturists ■ Some overseas travel.

□ Degree or equivalent in Food/Agricultural Science or other appropriate subject □ 5 years' R & D in meat or allied technologies □ Age under 30 □ Appointment as Higher Scientific Officer (£2800–over £3700) □ Ref: SA/29/JD.

□ Application forms (for return by 2 September 1974) from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

**Tropical Products Institute
Culham, Berks**

Cereal Technologist

■ R & D on composite flour technology, milling of tropical cereals, and preparation of food products of enhanced nutritional value from indigenous crops of less developed countries ■ Advise on cereal processes and products ■ Some overseas work.

□ Degree or equivalent in appropriate scientific/technical subject □ R & D experience in milling or bakery an advantage □ Age under 30 □ Appointment as Higher Scientific Officer (over £2550 to around £3500) or Scientific Officer (over £1700–£2800), according to age, qualifications and experience □ Ref: SA/30/JD.

□ Application forms (for return by 2 September 1974), from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

(620)

Experimental Biologist

A vacancy exists for an honours graduate in pharmacology, physiology or a related discipline to work on experimental aspects of thrombus formation. Experience in micromanipulative techniques is essential and an interest in innovation is desirable.

The position offers pleasant working conditions, excellent fringe benefits and opportunities for advancement. Salary scale £2,350 to £3,400.

Please apply in writing to Miss J. M. Dunbar, Inveresk Research International, Inveresk Gate, Musselburgh EH21 7UB, Midlothian, quoting reference 0441. (637)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (University of Reading)

A Scientific Officer or Higher Scientific Officer is required to join a group in the Bacteriology Department investigating the intestinal microflora of the neonate with particular reference to the antibacterial activity of milk. Experience with immunological techniques will be an advantage.

Candidates should have a degree, H.N.C. or equivalent qualification. Appointment will be in the grade of Scientific Officer (£1,592 to £2,675) or Higher Scientific Officer (£2,461 to £3,371), with a starting point dependent on qualifications and experience. At least five years' relevant post-qualifying experience is required for appointment in the higher grade. The post is pensionable.

Apply on forms obtainable from the Secretary, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT, quoting reference 74/17. (561)

UNIVERSITY OF EDINBURGH DEPARTMENT OF ASTRONOMY RESEARCH ASSISTANT IN INFRARED ASTRONOMY

Applications are invited for a post of Postdoctoral Research Assistant in observational infrared photometry from October 1, 1974. The appointment is for a period of one year, but extension will be considered.

The Research Assistant will continue the development of an existing infrared photometer, and its use in Tenerife and elsewhere for observations of H II regions and of extragalactic infrared sources.

Salary will be in the range £2,118 to £2,931 per annum with superannuation under F.S.S.U.

Applications, including curriculum vitae and the names of two referees, should be sent by August 24, 1974 to Dr M. J. Smyth, Department of Astronomy, Royal Observatory, Edinburgh EH9 3HJ from whom further information about the post can be obtained. Please quote reference number 5041. (591)

UNIVERSITY COLLEGE GALWAY

Professorship of Experimental Physics

Applications are invited for the above statutory whole-time post. Salary scale £5,427 x 141 (8) to £6,555, plus Family Allowances. Non-contributory Pension Scheme.

The closing date for receipt of applications is **September 16, 1974**. Prior to application, further information should be obtained from the Registrar of the College. (562)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Lecturer in the Department of Zoology. Preference will be given to candidates with an interest in terrestrial ecology.

Initial salary within the range £2,118 to £2,412 per annum, plus threshold payment, on a scale rising to £4,896 per annum, according to qualifications and experience.

Applications, stating age, academic qualifications and experience, together with the names of three referees should be received not later than August 23, 1974, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref. RV/N/276163. (607)

SEFTON AREA HEALTH AUTHORITY SOUTHERN DISTRICT PRINCIPAL BIOCHEMIST

with duties primarily at the new Fazakerley District General Hospital. There is a District Biochemistry service (serving about 2,500 beds), operated in conjunction with Walton Hospital (where there is a Principal Biochemist in post). Equipment includes some A.A.11 analysers, a Vickers M300, Wallace Autogamma counter and E.D.P. equipment.

Further particulars may be obtained from the Consultant Chemical Pathologist (Dr I. J. L. Goldberg) 051-525 5980 Ext. 310, with whom arrangements to visit the laboratories may be made.

Applications stating age, experience, qualifications and the names and addresses of three referees to be forwarded to Mr K. A. P. Gill, District Administrator, Sefton A.H.A.—Southern District, Walton Hospital, Rice Lane, Liverpool L9 1AE not later than September 3, 1974. (609)

Technical Field Officer

We require a Technical Field Officer, preferably aged between 20-25 years, (Male or Female), who has recently graduated with a science degree. His/Her main responsibilities will be to assist in the design, running and evaluation of field trials on current animal health products and the development of new products. There will be some involvement in the area of technical sales support.

This post offers a chance to obtain experience in commercial field research and development within a large international organisation.

The successful candidate will be provided with a company car, there is a non-contributory pension scheme in operation, together with assisted B.U.P. membership and other fringe benefits.

Please apply for an application form to:-

Mr K. G. Usher,
Head of Administration,
Elanco Products Ltd.,
Broadway House,
The Broadway,
Wimbledon,
London SW19 1RR.
Telephone No: 01-542 6600.
(594)

ROYAL POSTGRADUATE MEDICAL SCHOOL CHIEF TECHNICIAN

(H.N.C. or equivalent qualifications) required for Department of Clinical Pharmacology. Experience with modern analytical instruments, e.g. gas chromatographs and mass spectrometers desirable. The appointee will be expected to be fully involved with research projects and be responsible for the day-to-day running of the department.

Salary in range £2,907 to £3,516 per annum (plus threshold allowance).

Applications to the Secretary, R.P.M.S., Hamersmith Hospital, Du Cane Road, London W12 0HS, quoting Ref. No. 20/104N. (646)

Professor in Biology

ODENSE UNIVERSITY
DENMARK

Applications are invited for the above position which is to be filled as soon as possible after November 1, 1974.

Candidates should have research interests in experimental biology covering the areas of both ecology and physiology. Research at the Institute of Biology includes, among others, the fields of ecology, analytical/environmental chemistry and biochemical adaptation-physiology with special reference to the aquatic environment.

The professorship carries teaching responsibilities in experimental and environmental biology at an advanced level as well as involvement in the Institute's introductory biology courses.

The salary is regulated by law and cannot be negotiated, at present it is D. Kr. 174,164.01. Applications demonstrating research and teaching abilities commensurate with the position of professor together with reprints of relevant publications should be sent in 5 copies to the Administration, Odense University, Niels Bohrs Alle, DK 5000 Odense, Denmark no later than September 25. Inquiries can be sent to the Institute of Biology. (621)

Graduate in Biology

A vacancy exists for a graduate interested in cell biology to work in a small research team concerned primarily with wound healing. This involves the search for drugs which are beneficial to the healing process and more fundamental studies aimed at understanding the mechanism of cell movement and the control of cell division.

Modern equipment, including a scanning electron microscope is available, and a

high degree of practical ability and ingenuity is essential.

Pharmaceuticals Division is situated in rural North Cheshire and offers a good range of reasonably priced housing.

Applications in writing, requesting an application form, should be addressed to:

M. F. Losse, Personnel Officer,
ICI Pharmaceuticals Division,
Mereside, Alderley Park,
Macclesfield, Cheshire.

Pharmaceuticals
Division

(624)

UNIVERSITY OF STRATHCLYDE DEPARTMENT OF BIOCHEMISTRY

Research Assistant

Applications are invited for a post of Research Assistant in the M.R.C. Group for Biochemistry of Reproduction. Applicants who should preferably be at postdoctoral level or have equivalent experience, should have a good background in Biochemistry or cognate subject with interests in production in protein fractionation and isolation. Previous experience in reproductive studies would be an advantage but is not essential.

Appointment would be for the period October 1, 1974 to September 30, 1976.

Salary scale £2,118 to £2,412 with placing according to age and experience. F.S.S.U. benefits.

Applications (quoting R29/74) to Professor P. J. Heald, Department of Biochemistry, University of Strathclyde, Royal College, 204 George Street, Glasgow, G1 1XW from whom further information may be obtained.

(627)

DEPARTMENT OF EMPLOYMENT

Assistant Scientific Officers

The Department of Employment has vacancies for Assistant Scientific Officers with the Employment Medical Advisory Service, Baynards House, 1 Chepstow Place, Westbourne Grove, London W2 in the Central Reference Laboratory.

The duties are varied and mainly concerned with the examination of biological samples from industrial workers as an index of exposure to potentially toxic hazards. An aptitude for working with, or an interest in, modern laboratory equipment would be an advantage.

A knowledge of physio-chemical methods of analyses would be desirable.

QUALIFICATIONS

The minimum qualifications required are passes in 4 distinct subjects in GCE or equivalent. The passes must include English or English language, and a Science or Mathematical subject. Other acceptable qualifications are an ONC (candidates must have successfully completed the 01 year) the Intermediate examination of the Institute of Medical Laboratory Technology and Science Laboratory Technician's Ordinary Certificate. Alternative qualifications will be considered.

AGE

Candidates for all posts must be over 16 and normally under 26 years of age.

SALARY

£1,115 to £2,127 per annum according to age, inclusive of £228 inner London weighting, which is currently under review.

HOLIDAYS

Four weeks, rising eventually to six weeks.

HOW TO APPLY

Application forms from Mr D. C. Werran, Department of Employment (Est B3b), 12 St James's Square, London SW1Y 4LL.

Closing date for receipt of applications: September 6, 1974. (613)

NEW ZEALAND MINISTRY OF AGRICULTURE AND FISHERIES

SCIENTIST (PASTURE AGRONOMY)

INVERMAY AGRICULTURAL RESEARCH CENTRE,
MOSGIEL, SOUTH ISLAND, NEW ZEALAND

Duties: Study the effects of various cutting and grazing treatments on sward productivity and composition.

Investigate competitive mechanisms within establishing and permanent swards.

Qualifications Required: Ph.D., M.Agr.Sc. or M.Sc.

Salary: This will depend on qualifications and experience.

Passages and Incidental Expenses: The provision of assistance with fares and incidental expenses will be considered.

Application forms and general information are available from the New Zealand High Commission, New Zealand House, Haymarket, London SW1 Y 4TQ, with whom applications will close on September 13, 1974.

Please quote reference 4294 when making enquiries. (690)

UNIVERSITY OF EXETER DEPARTMENT OF CHEMISTRY S.R.C. POSTDOCTORAL RESEARCH ASSISTANTSHIP

SYNTHESIS OF MATERIALS FOR PHOTOELECTRIC ENERGY CONVERSION

Applications are invited from chemists with a good grounding in organic or inorganic or organo-metallic synthesis, to work on the preparation of potential photoelectric transducers. Some straight forward measurement of electrical properties will also be involved. Salary on scale £2,118 to £2,417 per annum, together with current threshold payments according to age and experience. Appointment for one year extendable to a second.

Applications naming two referees to Drs K. Kite, G. Read and D. R. Rossinsky, The University, Exeter EX4 4QJ, as soon as possible. Please quote reference 1/62/7077. (617)

UNIVERSITY OF HAMBURG RESEARCH ASSISTANT IN MEDICAL GENETICS

required for clinical and laboratory research and work in a genetics clinic. Salary in the range of £5,000 per annum net. Applicants should contact Dr Eberhard Passarge, Division of Cytogenetics and Clinical Genetics, Department of Human Genetics, Martini-strasse 52, 2000 Hamburg 20, W. Germany. Tel. (040) 468-3120. (623)

WEST BERKSHIRE HEALTH DISTRICT MEDICAL PHYSICS TECHNICIAN

for the modern Isotope Laboratory at the Royal Berkshire Hospital, Reading, for interesting work in the chemistry and physics of medical isotope techniques. Post will be on Grade V or Grade IV (£1,308 to £1,677 or £1,530 to £1,953). Day release for further training possible. (Normally O.N.C. or 2 'A' levels required).

Reading is a pleasant University town offering easy access to London, Oxford, Windsor, Henley and attractive surrounding countryside.

Written applications with relevant details and naming 2 referees to the Hospital Secretary, Royal Berkshire Hospital, London Road, Reading, Berkshire. (642)

"METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS. The work consists of editing, indexing, and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, 1 Carlton House Terrace, London SW1Y 5DB. (633)

SALOP AREA HEALTH AUTHORITY

Robert Jones and Agnes Hunt
Orthopaedic Hospital

OSWESTRY, SHROPSHIRE SY10 7AG

BIOCHEMIST

Graduate research assistant required to take part in investigations into the biology and biochemistry of muscle in relation to human musculo-skeletal disorders.

Salary in the range of £1,680 to £2,112 per annum.

Applications, with the names of two referees, should be addressed to:

• Dr M. Worsfold
Principal Research Biologist
Charles Salt Research Centre
Robert Jones and Agnes Hunt Orthopaedic
Hospital
Oswestry, Shropshire. (641)

KING'S HEALTH DISTRICT (TEACHING)

LAMBETH/SOUTHWARK/LEWISHAM AREA
HEALTH AUTHORITY (T)

GRADUATE RESEARCH ASSISTANT IN CYTOGENETICS

Applications are invited for the above post in the genetic sub-section of Haematology. Experience desirable. Salary according to N.H.S. Biochemist Scale.

Application forms obtainable from the Personnel Office, King's College Hospital, Denmark Hill, S.E.5 Tel.: 01-274 6222 Ext. 2726 (Miss Millwood). should be completed and returned by August 22, 1974. (616)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF GEOLOGY JUNIOR RESEARCH OFFICER

A vacancy exists for a Junior Research Officer in the above Department who will work under the direction of Professor T. S. Westoll, F.R.S., on Vertebrate Palaeontology with special emphasis on lower vertebrates.

The post is expected to be tenable for three years from October 1, 1974. It is particularly suitable for a recent graduate in Geology with good Zoological background, or in Zoology with some Geological background. A successful candidate may register for a higher degree, and though preference will be given to recent graduates other qualified persons are not excluded.

Salary will be at an appropriate point on the scale £1,569 by £81 to £1,731 by £87 to £1,818 according to age, qualifications and experience.

Applications (3 copies) giving a full curriculum vitae and the names of three referees, should be lodged with the Registrar, The University, Newcastle upon Tyne NE1 7RU not later than September 2, 1974. Please quote reference N. (618)

HUMAN PHYSIOLOGIST

required for research on inhaled drugs, asthma and exercise. Project could lead to higher degree. Salary according to qualifications and experience.

Applications, giving full details, to: Secretary, (N) Department of Child Health, Hammersmith Hospital Du Cane Road, London W12 0HS. (619)

TECHNICIAN (Grade 3)

required to assist in Biological research including projects on the diagnosis and immunology of cancer. Background of chemistry, biochemistry or pharmacology useful. Opportunities for further education up to H.N.C. Salary in range £1,650 to £1,920 plus £228 London Weighting plus threshold. Application forms from Personnel Officer (Technical Staff F.E.2), University College London, Gower Street, London WC1E 6BT. (622)

CHARING CROSS HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON)

The Animal Unit requires a RESEARCH ASSISTANT to collaborate with the Veterinarian in charge in the establishment of a quality control laboratory. The post would be suitable for a graduate or similarly qualified person with a background in microbiology or a relevant biological science. Starting salary not less than £1,350 depending upon experience.

For further information please contact: Head of Animal Unit, 55 Aspenlea Road, London W6 9HH. Telephone 01-385 7709. (628)

UNIVERSITY COLLEGE OF NORTH WALES Bangor

DEPARTMENT OF APPLIED ZOOLOGY

Applications are invited for the post of LECTURER IN APPLIED ZOOLOGY. The appointment will take effect from October 1, 1974 or as soon as possible thereafter.

Candidates should have an interest in either the epidemiological or experimental aspects of animal parasitology or in crop damage by ectoparasites (or insects).

Salary will be on the scale £2,118 to £4,896, according to age, qualifications and experience.

Further particulars may be obtained from the Secretary and Registrar, and applications (two copies) giving details of age, qualifications and experience, together with the names and addresses of three referees should be sent to reach the Secretary and Registrar, University College of North Wales, Bangor LL57 2DG, by August 27, 1974. (631)

CSIRO

AUSTRALIA

DIVISION OF BUILDING RESEARCH HIGHETT, VIC.

RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field:

RESIDENTIAL ENVIRONMENT

General: The Division has a total staff in excess of 300 including some 150 professional scientists. It undertakes research for the benefit of the Australian community into the theory, techniques and economics of building and community design, construction, and materials development and is seeking an understanding of the inter-action between the built environment and people. Programmes for studying the built environment are being developed in the context of both urban communities and remote settlements. The appointee will be located at Highett, Victoria.

Duties: To conduct research into the effects of the built environment, the relevant aspects of the natural environment and related factors of community living on residents or urban and remote settlements in Australia. This will involve the development of research techniques capable of providing guidance to physical and social planners and others who determine the nature of human settlements.

Qualifications: A Ph.D. degree or equivalent research experience, and demonstrable research ability. Applicants could be qualified in the relevant branches of psychology, sociology or geography, but graduates in architecture, planning or other disciplines, who consider that they have an appropriate background should not be deterred from applying. Experience in multi-disciplinary research teams involving social, physical and biological sciences would be an advantage.

Salary: Appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

Tenure: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 390/530 should reach:

**The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON WC2B 6BD.**

by the 30th August, 1974

Applications in U.S.A. and Canada should be sent to:

**The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.**

(625)

CSIRO**AUSTRALIA**

DIVISION OF FISHERIES AND OCEANOGRAPHY CRONULLA, N.S.W.

RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field:

FISHERIES BIOLOGY

General: The Division has a staff of about 50 scientists investigating the fisheries resources and the physical, chemical and biological features of the oceans. Headquarters of the Division is located at Cronulla, Sydney, and the Division has laboratories in Perth and near Brisbane. The appointee will be located at Cronulla.

Duties: To participate in investigations of marine fish resources around Australia. The appointee will be expected to develop and conduct his/her own programme. Initially attention will be directed to pelagic resources.

Qualifications: A Ph.D. degree or equivalent qualifications in one of the ecological sciences with training in Mathematics and Statistics, together with demonstrable research ability.

Salary: Appointment will be made within the salary range of Research Scientist: \$A9,698 to \$A12,194 p.a.

Tenure: An indefinite or 3 year fixed term appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 320/520 should reach:

**The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON WC2B 6BD**

by the 30th August, 1974

Applications in U.S.A. and Canada should be sent to:

**The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.**

(626)

ROYAL POSTGRADUATE MEDICAL SCHOOL TECHNICIAN (A.I.M.L.T.)

required for interesting post in the Postgraduate Teaching Laboratories. The department deals with a wide range of work in all the four major disciplines of Clinical Pathology, and offers good facilities for further studies.

Applicants qualified in Histology (or Bacteriology) preferred. Applications to the Secretary, R.P.M.S., Hammersmith Hospital, DuCane Road, London W12 0HS, quoting Ref. No. 9/102N. (629)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (UNIVERSITY OF READING) INFORMATION OFFICER

An information scientist, preferably with a degree in microbiology or biochemistry, is required to take part in the new information service of the Institute.

Appointment will be in the Scientific Officer Class, with a starting salary dependent on qualifications and experience. Present scales Scientific Officer £1,592 to £2,675; Higher Scientific Officer £2,461 to £3,371. At least five years' relevant post-qualifying experience is required for appointment in the higher grade. The post is pensionable.

Apply on forms obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT. Quote reference 74/20. (630)

NATIONAL INSTITUTE FOR BIOLOGICAL STANDARDS AND CONTROL

TECHNICIAN

DIVISION OF VIRAL PRODUCTS

We require someone with H.N.D., H.N.C. or equivalent for work concerned with the control and development of viral vaccines and involving the manipulation of viruses under sterile conditions in various types of cell cultures. Other procedures such as radio-isotope labelling and radioimmuno assays are also employed. A knowledge of basic microbiological techniques would be an advantage plus an ability to work without direct supervision.

Salary on scale £1,683 to £2,577 including London Weighting.

The Institute is situated in pleasant surroundings close to Hampstead Underground Station. There is an active sports and social club plus superannuation benefits. Please apply giving brief details (an application form will be sent to you) to R. S. Dunn, Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, Hampstead, N.W.3. Tel. 435 2232. Please quote Ref. 0027. (649)

THE UNIVERSITY OF SHEFFIELD RESEARCH ASSISTANT

ACADEMIC DIVISION OF MEDICINE

Applications are invited for a RESEARCH ASSISTANT to join a group working with Professor D. S. Munro on human thyroid disorders. The work will include the development of new assay methods for circulating thyroid stimulating factors in health and disease. A graduate with a degree in Chemistry or in a biological science is sought. Salary up to £1,929 according to qualifications and experience. A successful candidate wishing to read for the degree of Ph.D. would be offered a Research Studentship, £695 a year and fees. Further particulars from The Registrar and Secretary to whom applications (one copy only) should be sent by August 27, 1974. Please quote reference R124/G. (632)

BIOCHEMISTRY TECHNICIAN

required to join group investigating enzyme kinetics of muscle proteins. Applicants should have degree or H.N.C. in Biochemistry or Chemistry. Previous laboratory experience in the use of biochemical and radioisotope techniques preferred. Salary on the scale £1,173 to £2,073 plus £126 London Weighting according to age and experience.

Applications to John Cribbin, M.R.C. C.E.11 Biophysics Unit, 26-29 Drury Lane, W.C.2. (643)

UNIVERSITY OF LEEDS DEPARTMENT OF PLANT SCIENCES

Applications are invited from graduates in Botany, Biochemistry or other suitable branch of Biology, for two posts of RESEARCH ASSISTANT in the Department of Plant Sciences.

- A three year project to work on the control of nucleic acid synthesis in the cell cycle of fungi. This project will involve nucleic acid fractionation, DNA/RNA hybridisation studies and some microscopy.
- A one year project to work on biochemical aspects of fungal disease in plants. This project will involve working with animals to raise antisera.

Salaries on the scale £1,449 to £1,818 p.a. according to experience (at present under review).

Applicants should write directly to Dr J. A. Callow, Department of Plant Sciences, quoting 2 referees, as soon as possible. (614)

Histology Technician

required for Pharmacological and Toxicological Laboratory. Experience essential in the preparation and processing of animal tissues. Good working conditions. Pension and Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB.

(640)

UNIVERSITY OF EXETER

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a Postdoctoral Research Assistantship in theoretical physics supported by the Science Research Council. The research work, with Dr. T. W. Preist, will involve the use of Faddeev methods to study rearrangement collisions at thermal energies and should be of interest to applicants with experience in either Atomic, High-Energy or Nuclear physics.

The appointment is for two years from October 1, 1974 (starting salary £2,118 plus F.S.S.U.). Applications giving details of experience and qualifications and including the names of two referees should be sent, by August 23, 1974 to Miss S. Chinn, Department of Physics, University of Exeter, Stocker Road, Exeter EX4 4QL (Tel. Exeter 77911 ext. 625) from whom further information may be obtained.

Ref. 1/12/7079.

(668)

THE QUEEN'S UNIVERSITY OF BELFAST

Department of Biochemistry

Postdoctoral Research Assistant

Applications are invited for an S.R.C. Postdoctoral Research Assistantship for work in collaboration with Dr R. J. H. Davies on the PHOTO-CHEMISTRY AND PHOTOBIOLOGY OF PURINES. The project will involve an assessment of the photo-reactivity of purines in nucleic acids, polynucleotides and simpler model systems. The primary aim of this research is the identification of purine photoproducts and an evaluation of their biological consequences. Previous experience in the isolation and chemical characterization of natural products would be an advantage though not essential.

The appointment is for two years from October 1, 1974, or an agreed date thereafter, at a salary of up to £2,247 by £165 p.a. (with F.S.S.U.) depending on age and experience. Applications, together with the names of two referees, should be sent to the Personnel Officer, Queen's University, Belfast BT7 1NN, from whom further particulars are available.

(663)

SYDNEY HOSPITAL

New South Wales

Australia

**Staff Specialist
in Intensive Care**

Applications closing September 15, 1974, are invited from suitably qualified medical practitioners for the position of Staff Specialist In Charge of the Intensive Care Unit at Sydney Hospital.

Teaching at both undergraduate and postgraduate levels is an integral part of the position.

Salary and conditions are those set out in the Hospital Specialist (State) Award (range \$A15,203 to \$A21,006). The Award is presently under review. The limited right of private practice is available under the terms laid down by the Health Commission of New South Wales in circular 72/78. The terms allow earnings up to 16 per cent of base rate salary.

Under certain circumstances The Board may give consideration to two part time appointments to this post. Further enquiries may be directed to The Director of Anaesthesia.

Sydney Hospital is a 460 bed teaching hospital of the University of Sydney. It conducts a wide range of medical, surgical and special surgical services and is accredited for post graduate training in general and special medicine and surgery.

The Director of Anaesthesia will be visiting the United Kingdom in August/September. Applications in writing, stating age, training, experience and the names of three referees should be directed as follows:-

1st copy to Dr F. R. Berry, C/- Bank of New South Wales, 9-15 Sackville Street, London.

2nd copy by airmail to The General Medical Superintendent, Sydney Hospital, Box 1614, GPO, Sydney, 2001, New South Wales. (610)

nature**EDITORIAL SECRETARY**

We are looking for someone who will be involved in both the editorial and production processes and has:

- A good basic knowledge of science
- An eye for detail
- Shorthand and typing

Although not essential, a knowledge of production work would be an advantage.

Write, giving personal details, to:

- The Editor, *Nature*, Macmillan Journals Ltd,
4 Little Essex Street, London WC2R 3LF.

STATE OF KUWAIT

Kuwait University—Academic Posts for 1974-1975

Applications are invited for teaching posts in Marine Ichthyology, Marine Fisheries & Mariculture, Oceanography, Immunology, and Marine Parasitology. Contracts start on February 1, 1975 for two years, renewable for a further period of four years if convenient to both applicant and University.

Applicants should be:

- (a) Holders of an academic Post at present in an accredited University or research center.
- (b) Ph.D. holders

Curriculum vitae forms are obtainable from Kuwait Embassies in Washington D.C. (Cultural Division, 4301 Connecticut Avenue, N.W., Site 158, Washington, D.C. 20008) and London, (Cultural Attache office, (Al-Jahra House, 3 Stratford Place, London W1N 9AE) or from Kuwait University, Kuwait. Completed forms, together with copies of the candidate's publications, must be received by Kuwait University, Kuwait, not later than September 30, 1974.

Those who applied before can renew their applications by writing to the University.

Salaries are within the range of Kuwaiti Dinars 3,900 to 6,660 per annum, tax free (K.D.=£2.90)

Candidate is also entitled to the following privileges:

1. Annual return air tickets to his country, would be provided to him, his wife and three of his children not exceeding the age of twenty.
2. Free furnished accommodation with water and electric supplies.

(648)

NEW ZEALAND

Department of Scientific & Industrial Research

Applications are invited for the position of Scientist (Soil Physics) with the Soil Bureau, DSIR, Lower Hutt, where there is a vacancy for a senior soil physicist in the soil physics section.

Salary: Up to NZ\$10,232 p.a. dependent on qualifications and experience.

Duties: Work of the section includes systematic studies of the physical properties of soil in relation to soil classification and effects of modification of soils by man, and will expand into the field of soil evaluation for irrigation and effluent disposal.

Qualifications: PhD. or good Honours degree in soil physics, with experience in field operation support and irrigation planning desirable.

Passages: Fares for appointee and his wife and family, will be paid.

Incidental expenses: Up to NZ\$120 for a single man and NZ\$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ, with whom applications will close on 13 September 1974. Please quote reference P/T 113 when enquiring. (666)

ROYAL POSTGRADUATE MEDICAL SCHOOL TECHNICAL OFFICER

required for M.R.C. Team involved in assaying new metabolic hormones and assessing their role in health and disease. This post is suitable for a new graduate in Biochemistry or Physiology and could offer opportunities for a higher degree. Salary according to age and experience.

Applications to the Secretary, R.P.M.S., Hammersmith Hospital, DuCane Road, London W12 0HS quoting ref. no. 2/149. (662)

UNIVERSITY OF READING TECHNICIAN (Grade 3)

required in Department of Microbiology to assist a group engaged in research on the genetics and biochemistry of bacteria and to prepare materials for practical classes. Salary in the range £1,650 to £1,920 p.a. according to qualifications and experience. Apply quoting Ref: TN68, stating qualifications and experience and giving the names of two referees to Senior Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. (670)

UNIVERSITY OF NOTTINGHAM Department of Electrical and Electronic Engineering

Applications are invited for appointment as LECTURER in this Department. The salary scales range from £2,118 to £4,896, but the appointment will be made initially within the first three points of the scale. The appointment can be made from October, 1974, or from a later date to be arranged.

Applicants should preferably have had industrial, research or lecturing experience in communications, control or electronics. The person appointed will be expected to pursue research in addition to their teaching duties, for which facilities are available.

The appointment will be subject to the terms and conditions of the Grading and Salary Scheme, a copy of which is available on request. The successful applicant will be required to join the Federated Superannuation System for Universities, under the terms of which there is an annual premium of 15% of the salary. The University will pay two-thirds of this premium and the member one-third. The University reserves the right to appoint to the post a person who has not submitted an application.

Further particulars and forms of application, returnable not later than August 31, 1974, are obtainable from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD Job No. 389. (667)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF METALLURGY

Applications are invited from Honours graduates in Metallurgy, Materials Science, Engineering or Pure Science for the post of

RESEARCH ASSISTANT

which becomes vacant on October 1, 1974. Preference will be given to candidates who have had some research or industrial experience. The post is a full-time research appointment with the opportunity to work for a higher degree of the University. A wide range of research topics is available in chemical, physical or engineering metallurgy and it will be possible to match the nature of the research to the interests of the person appointed. The appointment is for one year in the first instance with the possibility of annual re-appointment.

Salary £1,764 to £1,839 with F.S.S.U.

Applicants should send a brief statement of their academic qualifications, experience and research interests to Professor K. M. Entwistle, U.M.I.S.T., P.O. Box 88, Sackville Street, Manchester M60 1QD. (656)

UNIVERSITY OF KHARTOUM SUDAN

Applications are invited for the following posts in the Faculty of Medicine:—

1. PROFESSOR/SENIOR LECTURER OR LECTURER (4 posts) in ANATOMY. Applicants must be medically qualified and must hold a Ph.D. or equivalent or a postgraduate diploma in Anatomy. Candidates will be assessed for the respective status according to research and relevant teaching experience in Anatomy (Regional and Applied) plus a sound knowledge of Neuro-Anatomy and/or Embryology and/or Histology.
2. SENIOR LECTURER/LECTURER (2 posts) IN BIOCHEMISTRY.

Salary scales: Senior Lecturer £52,400 to £52,800 p.a., Lecturer £51,500 to £52,300 p.a. (£1 sterling=£50.82). The British Government may supplement salaries in range £1,300 to £1,600 p.a. (sterling) for married appointees or £800 to £900 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. These rates of supplementation are currently under review. Family passages; various allowances; superannuation scheme; annual overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than September 4, 1974 to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicant resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (650)

Senior Biochemist

A leading British pharmaceutical Research Organisation has a vacancy for a **Senior Biochemist** to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for an Application Form from The Secretary, Biorex Laboratories Limited, Biorex House, Canonbury Villas, London N1 2HB. (655)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

University of Reading

HEAD OF DEPARTMENT of PROCESS ENGINEERING

A vacancy will occur on the retirement of Mr. H. S. Hall, O.B.E. for a suitably qualified person to direct and organise the Institute's research and development programme on the processing of milk and milk products.

Candidates should have a degree in engineering or an allied science and have had relevant experience in research and in the industrial processes concerned with milk or food products.

The post, which is pensionable, will be graded as Senior Principal Scientific Officer (salary £6,300 by 3 increments to £7,280). Further particulars and forms may be obtained from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT and applications should be returned to him by October 1, 1974. Quote reference 74/26. (671)

UNIVERSITY COLLEGE LONDON

Department of Biophysics

ELECTRON-MICROSCOPIST

RESEARCH ASSISTANT required to work with Professor R. Miledi on problems in Neurobiology, which forms part of a Long Term Project supported by the M.R.C.

Preference given to applicants with experience of freeze-etching or analytical electron-microscopy. Salary within Lecturer scale plus London Allowance.

Applications with curriculum vitae and names and addresses of two referees to Mrs. K. Garnons-Williams, (N) Biophysics Dept., University College London, Gower St. London WC1E 6BT. (680)

Manchester Area Health Authority

(Teaching) South District

WITHINGTON HOSPITAL,
MANCHESTER M20 8LR.

GRADUATE required with a good honours degree in biochemistry. The appointee will take part in research into thrombosis and development work in the National Reference Laboratory for Anticoagulant Control Reagents at Withington Hospital.

Further information can be obtained from Dr. L. Poller, Consultant Haematologist, Withington Hospital.

Applications with the names of two referees to the Hospital Secretary, quoting ref. B 22. (52135). (657)

Countryside Commission

The Countryside Commission maintains close liaison with organisations throughout England and Wales which share its concern with the conservation of the countryside and with the recreational opportunities it can offer. There are specialist posts, at the Commission's new Headquarters in Cheltenham, for experts who have the ability to originate ideas and to communicate them effectively both orally and in writing.

AGRICULTURALIST

to give advice on agricultural matters arising from submitted schemes, promote research and experiments into the integration of landscape conservation and recreation with farming, and liaise with M.A.F.F., N.F.C. and Country Landowners Association. (Reference SB/1/HG).

Candidates (normally aged under 32) must hold a 1st/2nd class honours degree in agriculture or other appropriate scientific subject and have at least 4 years' postgraduate experience. Practical involvement in farming will be an advantage.

ECOLOGIST

to give ecological advice on schemes under consideration, instigate and supervise research and experiments into environmental capacity for recreation, promote action to conserve wild-life in country parks, and liaise with Nature Conservancy Council. (Reference SB/2/HG).

Candidates (normally aged under 32) must hold a 1st/2nd class honours degree in botany, zoology, biology or other appropriate scientific subject and have at least 4 years' postgraduate experience, including conservation work or qualification in ecology or conservation.

Starting salary in the range £3,250 to around £4,550, according to qualifications and experience. Prospects of promotion. Non-contributory pension scheme.

For full details and application form (to be returned by September 5, 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB or telephone Basingstoke 29222 ext 500 or London 01-839 1992 (24 hour answering service). Please quote appropriate reference. (669)

UNIVERSITY OF IBADAN

NIGERIA

Applications are invited for the following posts in the Faculty of Science:—

- PROFESSOR IN DEPARTMENT OF BOTANY.** Applicants should be Botanists with several years' post-doctoral teaching and research experience, and should be familiar with the organisation and supervision of postgraduate research with particular reference to tropical plants and the use of modern laboratory equipment. Appointee will be expected to administer and plan the development of the University Botanical Gardens and Herbarium as well as the Department of Botany.
- SENIOR LECTURER AND LECTURER IN THE DEPARTMENT OF GEOLOGY.** For Senior Lectureship, appointee will be expected to lead research in either Geophysics, Geochemistry with a bias for Mineral Exploration, or Mineralogy with a bias for X-Ray Diffraction. The Geophysicist should have a bias in Exploration and should be conversant with most geophysical methods. He will be expected to supplement Petrological and/or Mineral Exploration Research in the Department with geophysical data. The Mineralogist should have long experience with X-Ray Crystallography and should be particularly interested in X-Ray Diffraction. For Lectureship, appointee should have special interest or experience in one of the following areas: Engineering Geology with strong background of rock mechanics and/or hydrogeology; Mineralogy with special bias in optical and X-ray crystallography and with experience of X-ray diffraction and power camera work; Igneous Petrology; Experimental Geology.

Salary scales: Professor N6,600 p.a. Senior Lecturer N5,030 to N5,750 p.a. Lecturer N2,760 to N4,830 p.a. (N1 sterling=N1.46). The British Government may supplement salaries in range £750 to £1,500 p.a. (sterling) for married appointees or £250 to £1,000 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than September 6, 1974 to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to the Inter-University Council, 90/91, Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (677)

May & Baker Ltd. Drug Metabolism.

A vacancy exists in the Drug Metabolism Division for a graduate, preferably with relevant post-graduate experience and degree. The work of the Division involves studies on the metabolism and pharmacokinetics of new medical products and as such, requires familiarity with metabolic processes, instrumentation applicable in the field and the ability to devise new analytical methods. Preference will be given to a candidate who has a good knowledge of pharmacokinetics and the associated use of computers.

Publication of appropriate work is encouraged. There are active links with a number of university departments, units of clinical pharmacology and physicians involved in

drug trials. Various attractive residential areas are within easy reach of the research site and help will be provided with removal expenses where appropriate.

Applications, giving details of qualifications and experience should be addressed to the Personnel Manager, May & Baker Ltd, Dagenham, Essex RM10 7XS, quoting reference number 194/N/1. (674)

M&B May & Baker

FOOD & AGRICULTURE ORGANISATION
OF THE UNITED NATIONS

Viale delle Terme di Caracalla, Rome, Italy

FISH CULTURIST

Applications are invited for the post of a Fish Culturist for the Khmer Republic under the F.A.O./U.N.D.P. Programme from candidates with a University degree or equivalent in fisheries sciences and several years' experience in the field of fish culture in tropical countries. Very good knowledge of English or French is essential. Duty Station—Phnom Penh.

The duties and responsibilities of the post include (1) to assist in the establishment of a fish hatchery/demonstration fish farm station; (2) to set up and demonstrate modern methods of aquaculture in fish cages; (3) to train counterpart personnel and fish farmers in the techniques of pond and cage fish culture.

Salary: US\$16 542 to US\$21 294 net (tax free), plus Cost of Living Adjustment and other allowances.

Further details can be obtained from the Personnel Officer, Department of Fisheries, F.A.O., Rome. Closing date for receipt of applications: September 15, 1974. (661)

GUY'S HOSPITAL MEDICAL SCHOOL

Applications are invited for the post of

Graduate in Research Assistant in Cytogenetics

The work will be concerned with diagnostic chromosome analysis but, in addition, the successful applicant will be encouraged to participate in research projects.

Applications should be sent to the Administrative Secretary, Paediatric Research Unit, Guy's Hospital Medical School, London Bridge, SE1 9RT, as soon as possible. (658)

THE POLYTECHNIC, WOLVERHAMPTON

DEPARTMENT OF BIOLOGICAL SCIENCE WELCOME TRUST POST DOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited from suitably qualified persons to assist in investigations of the function of intestinal microperoxisomes with special reference to factors influencing lipid and cholesterol synthesis. Applicants should hold or expect to hold a Ph.D. in Biochemistry (or related area). The appointment is tenable for 3 years.

Salary in the range £2,223 by increment to £2,553.

Further details and application forms may be obtained from: The Establishment Officer, The Polytechnic, Wolverhampton WV1 1LY. Telephone 27371 Ext. 94. (673)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the following posts in the Faculty of Medicine:—

1. SENIOR LECTURER / LECTURER / ASSISTANT LECTURER IN THE DEPARTMENT OF MICROBIOLOGY. Duties of appointee, will include routine Clinical Microbiology work for the University Hospital and instructions in Microbiology to students working for the medical degree of the University. Duties to be assumed as soon as possible.
2. LECTURER IN HAEMATOLOGY in the Department of Pathology. Appointee will be attached to the University Hospital and will teach medical students for the M.B., B.S. degree of the University, in co-operation with the Consultant staff of the Hospital.

Salary scale: Medically qualified: Senior Lecturer J\$10,992 to J\$14,472 p.a. Lecturer J\$7,860 to J\$10,752 p.a. Assistant Lecturer J\$6,300 to J\$6,900 p.a. Non-Medically qualified: Senior Lecturer J\$8,460 to J\$12,492 p.a. Lecturer J\$6,168 to J\$9,768 p.a. Assistant Lecturer J\$5,006 to J\$5,468 p.a. (£1 sterling = J\$2.17). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years. Thereafter 20% of salary paid in lieu of housing. Family passages; triennial study leave. Detailed application (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source before an application is made. (679)

Pharmacologists/ Toxicologists

Honours Graduates with some experience required for Research and short and long term toxicological studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratory. Pension and Assurance Scheme. Application Forms from: The Secretary, Biorex Laboratories Limited, Biorex House, Canonbury Villas, London N1 2HB. (654)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH
ASSISTANT

Applications are invited for a postdoctoral Research Assistant to work in collaboration with Dr. J. W. Tucker on a theoretical investigation of phonon scattering by paramagnetic ions. The appointment, which is financed by the Science Research Council, will be for a period of two years. The post is available from August 1, 1974. Initial salary £1,929 a year rising to £2,118 on October 1, 1974 with F.S.S.U. provision. Applications, stating qualifications and experience together with the names and addresses of two referees should be sent as soon as possible to Dr. J. W. Tucker, Department of Physics, The Hicks Building, The University, Sheffield S3 7RH. Quote Ref R. 125/G. (675)

UNIVERSITY OF THE WEST INDIES
TRINIDAD

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN AGRICULTURAL EXTENSION in the Faculty of Agriculture. Appointee should be a specialist in Agricultural Extension and should have experience in teaching and research in the field. Salary scales: (a) TT\$17,304 to TT\$25,824 p.a. (b) TT\$12,612 to TT\$20,316 p.a. (£1 sterling=TT\$4.8). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years, thereafter 20% salary in lieu of housing. Family passages; study leave. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Secretary, University of the West Indies, St. Augustine, Trinidad. Further particulars will be sent to all applicants. (678)

ZOOLOGISTS

Zoology graduates are invited to join the editorial team working on Aquatic Sciences and Fisheries Abstracts, an international publication. Starting salary is £1,725 per annum. Write to: Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (682)

UNIVERSITY OF MELBOURNE
LECTURESHIP
(LIMITED TENURE—3 YEARS)
DEPARTMENT OF PHYSIOLOGY

Applications are invited for this position. Qualifications: Applicants should have teaching and research experience in Physiology, and a Ph.D. in Physiology, a medical degree, or an equivalent qualification.

Duties: The appointee will participate in the departmental teaching activities, including the organising and supervision of laboratory exercises for undergraduate students.

It is anticipated, but not essential, that the appointee's research interests relate to one of the fields being studied at present in the department; these include lipid metabolism, renal, respiratory and cardiovascular function, haematology and physiology of the nervous system with emphasis on sensory processes.

Salary: \$A9,002 to \$12,352.

Commencing date: January 1, 1975 or as soon as possible thereafter.

Further details may be obtained from Professor I. Darian-Smith, Department of Physiology in the University.

Conditions of appointment and application procedure from the Registrar, University of Melbourne, Parkville, Victoria 3052, Australia, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications close on September 6, 1974.

(684)

MEMORIAL UNIVERSITY OF
NEWFOUNDLAND
Department of Geology

Applications are invited for the post of RESEARCH ASSOCIATE (ELECTRON PROBE MICROANALYSIS).

Duties: Will include routine care, maintenance and supervision of an automated electron probe micro-analyser. The appointee will also be required to train microprobe users and assist in the preparation of specimens.

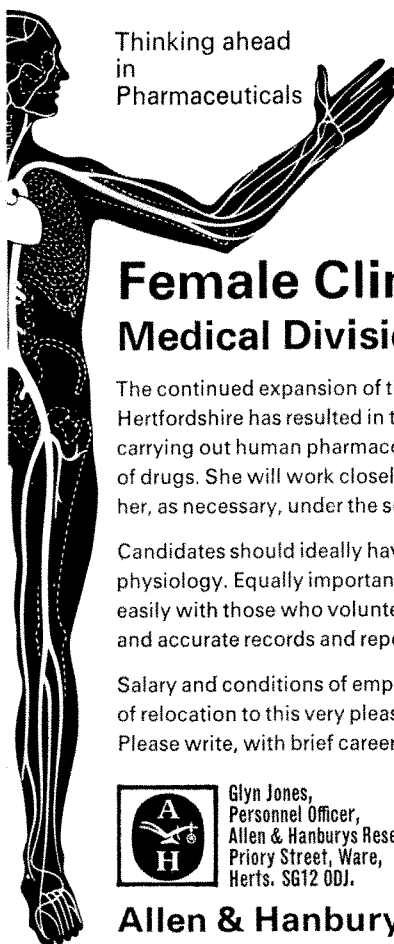

Qualifications: An appropriate degree or diploma, preferably an M.Sc. or Ph.D. Experience in electronics, microprobe analytical techniques and computing procedures would be an advantage.

Tenure: Initially for a two-year period.

Salary: To be negotiated, depending on qualifications and experience.

Application: Written application stating full personal particulars and details of qualifications and experience together with names and addresses of three referees should be sent to Dr. K. D. Collerson, Department of Geology, Memorial University of Newfoundland, St. John's, Newfoundland, Canada. (685)

Thinking ahead
in
Pharmaceuticals

Female Clinical Assistant Medical Division

The continued expansion of the activities of our Medical Division at Ware in Hertfordshire has resulted in the need to recruit a graduate, who will assist in carrying out human pharmacological investigations associated with the testing of drugs. She will work closely with a Senior Scientific Officer and deputise for her, as necessary, under the supervision of a Senior Medical Officer.

Candidates should ideally have a background in pharmacology and/or physiology. Equally important is the ability to understand and communicate easily with those who volunteer to take part in the tests, and to maintain concise and accurate records and reports of her work.

Salary and conditions of employment are attractive. Assistance with the cost of relocation to this very pleasant rural area will be given, where appropriate. Please write, with brief career details, to

Glyn Jones,
Personnel Officer,
Allen & Hanburys Research Ltd.,
Priory Street, Ware,
Herts. SG12 0DJ.

Lakehead University

THUNDER BAY, ONTARIO, CANADA

NUTRITION AND FOOD SCIENCE

Applications invited for position, rank open, in Nutrition and Food Science; Ph.D. or equivalent, with concentration in community nutrition preferred—to teach undergraduate courses, conduct research and assist in curriculum development.

Salary commensurate with experience and rank. 1974 floors: Professor \$21,630; Associate Professor \$17,235; Assistant Professor \$13,865.

Send curriculum vitae and names of three referees to:

Mr Donald E. Ayre
Secretary of the University
Lakehead University
THUNDER BAY, Ontario
P7B 5E1

(687)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following vacancy:—

LECTURE

in Stratigraphy in the Department of Geology. Salary Range: £2,118 to £4,896. Duties to commence January 1, 1975. Closing date September 14, 1974.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff, CF1 1XL, from whom further particulars may be obtained. Please quote ref. 0628.

(689)

UNIVERSITY DURHAM DEPARTMENT OF BOTANY

An S.R.C. Research Technician (Grade 3) is required for 3 years from October 1, 1974, to work with Dr. J. A. Pearson and Mr. G. H. aBnury on ferritin and nucleic acid synthesis in *Phycomyces blakesleeanus*. A graduate with experience in microbial biochemistry would be preferred, but other suitably qualified persons may apply. Starting salary £1,605 p.a. plus threshold payments.

Applications in writing, naming two referees, should be sent to the Deputy Personnel Officer, University of Durham, Old Shire Hall, Durham, DH1 3HP, to arrive by Friday, August 23.

(692)

Research Biologist

Cell Biology is one of the newer activities of our Research Function, involving cell and tissue culture and microbiological work. We are now seeking a senior technical assistant to join a small well knit group working in these fields.

The main scientific duties of the appointee would be concerned with fermentation and antimicrobial testing. In addition, he would be responsible for several junior technicians and for general laboratory management of the Cell Biology Unit.

The senior assistant is likely to be aged 25-35 with at least ONC and preferably HNC in applied biology. Experience of either fermentation or antifungal/antibacterial screening over a period of at least 3 years would be a distinct advantage although general experience in a microbiological laboratory would also be useful.

If you would like to be considered for this post please telephone (Welwyn Garden 28128) or write to the Personnel Manager quoting reference RH25 for a Confidential Record Form and further information on the Company.

Roche Products Limited
Welwyn Garden City Hertfordshire AL7 3AY

(706)

THE UNIVERSITY OF THE WEST INDIES—TRINIDAD EXECUTIVE DIRECTOR

PROPOSED CARIBBEAN AGRICULTURAL RESEARCH AND DEVELOPMENT INSTITUTE

Applications are invited for the post of Executive Director of the Caribbean Agricultural Research and Development Institute (CARDI) which is to be established by the member Governments of the Caribbean Community as the successor organisation to the Regional Research Centre of the Faculty of Agriculture of the University of the West Indies. The Institute has been established to serve the research and development needs of the region and will have its headquarters at the St. Augustine, Trinidad, campus of the University of the West Indies.

Applicants should possess a good degree in agriculture or one of its related fields. A higher degree, though not essential, would be a distinct advantage.

The person appointed will have had considerable experience in tropical agriculture or agricultural research and development and/or be an administrator of exceptionally high calibre. Experience with the region would be an advantage.

The Executive Director will be responsible for the day to day control, management and administration of the Institute.

The appointment will be on contract for five years in the first instance. Salary will be negotiable based on qualifications and experience. Other allowances are payable. A gratuity in lieu of pension will be paid. Unfurnished accommodation will be provided at a cost of 10% of salary. Alternatively a housing allowance of 20% salary will be paid in lieu of accommodation. Four weeks annual leave will be granted. Up to five full passages will be provided on appointment and on normal termination.

The person appointed would be expected to assume duties as soon as possible and preferably by October 1974.

Applications giving full details of date of birth, marital status, qualifications and experience and the names and addresses of three referees should be sent by airmail, as soon as possible to the Secretary, University of the West Indies, St. Augustine, Trinidad from whom further particulars can be obtained.

(676)

UNIVERSITY OF RHODESIA LECTURESHIPS IN THE DEPARTMENT OF BOTANY

Applications are invited for the posts of LECTURER IN MICROBIOLOGY AND LECTURER/SENIOR LECTURER IN PLANT PHYSIOLOGY. Special consideration will be given to applicants for the microbiology post with experience in plant virology and serology. The appointee to the plant physiology post will have prime responsibility for all teaching and research in plant physiology.

Salary Scales (Approximate £ Sterling equivalents): Senior Lecturer: £5,484 by 219 to £7,239. Lecturer Grade I: £4,984 by 184 to £5,720. Lecturer Grade II: £3,071 by 158 to £3,545 by 175 to £3,895 by 185 to £4,635 by 174 to £4,809.

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid schemes.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications, and naming three referees, should be submitted by **August 31, 1974**, to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Applicants from outside Southern Africa should send a copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. (687)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited for the post of Post Doctoral Research Assistant from October 1, 1974 or January 1, 1975. The successful candidate will be expected to pursue a research and development programme involving the application of neon flash tubes to nuclear particle detection with special reference to high energy γ -radiation. The programme will involve work at the Science Research Council's high energy accelerators.

The appointment, which is funded by the Science Research Council, will be for a period of two years.

The salary will be on the scale from £2,055 to £2,793 with F.S.S.U. benefits.

Applications (3 copies) including the names and addresses of three referees should be sent by September 2, 1974, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (691)

DEPARTMENT OF BIOPHYSICS TECHNICIANS Grade 3

required to assist with research project as follows:

(1) **BIOCHEMISTRY TECHNICIAN** with experience in protein separation techniques.

(2) **ELECTRON-MICROSCOPE TECHNICIAN** with experience in autoradiography.

Salary in range £1,650 to £1,920 plus £228 London Weighting plus Threshold.

Application form from Personnel Officer (N) (Technical Staff FD1), University College London, Gower Street, WC1E 6BT. (696)

CHELSEA COLLEGE UNIVERSITY OF LONDON

(In association with St. George's Hospital Medical School and the Royal Dental Hospital of London School of Dental Surgery)

LECTURER IN BIOCHEMISTRY

Applications are invited for the post of LECTURER in the Biochemistry Department of the Basic Medical Science Group of Chelsea College, from October 1, 1974. The person appointed must be willing to become wholeheartedly involved in the undergraduate and postgraduate teaching of an active expanding department, and be prepared to participate in the work of the other sections of the Group and of the collaborating Medical and Dental Schools. The successful candidate will also be expected to maintain an active commitment to research, preferably in collaboration with other workers in the Group or associating Schools. Salary Scale: £2,118 to £4,896 per annum plus £213 London Allowance. Further particulars and application forms from the Personnel Officer N, Chelsea College, Manresa Road, London SW3 6LX. Closing date August 28, 1974. (697)

THE UNIVERSITY OF MANCHESTER

Department of Medical Oncology
(Christie Hospital and Holt Radium Institute)

Applications are invited for the following posts in the new Department of Medical Oncology at Christie Hospital.

1: LABORATORY TECHNICIAN

Duties will include cryopreservation of cells and assistance with research in the field of human tumour immunology. Applicants should have an O.N.C. or equivalent qualification and at least 3 years' background experience preferably in tissue culture or cellular immunology. Salary scale £1,650 to £1,920 per annum.

2: MEDICAL LABORATORY TECHNICIAN IN HAEMATOLOGY

Work will involve a number of research projects in the field of tumour immunology in patients with malignant diseases of the haematopoietic system. Applicants should have the A.I.M.L.T. in haematology and at least 2 years' experience in haematology following qualifications. Commencing salary up to £1,905 per annum on scale for Medical Laboratory Technicians (£1,557 to £2,451 per annum).

Applications with full details of age, qualifications and previous experience should be sent to Professor D. Crowther, Dept. of Medical Oncology, Christie Hospital and Holt Radium Institute, Withington, Manchester M20 9BX. (688)

UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY Research Assistantship in Marine Biochemistry

Applications are invited for an S.R.C. post-doctoral research assistantship to work on the control of fat metabolism in fish and other lower animals for three years. The assistant would spend the first year in the Biochemistry Department, Oxford, learning and developing techniques associated with enzymes of fat metabolism. The following two years would be spent at the Marine Biology Laboratory, Plymouth. It is expected that close collaboration between Oxford and Plymouth will be maintained during the course of this work. Preference will be given to candidates who have had a research training in Biochemistry but who have also had some experience of Zoology or Marine biology.

The salary will be on the scale £1,920 to £3,636 p.a. with F.S.S.U. membership.

Applications, giving brief curriculum vitae and names of two referees, should be addressed to Dr. E. A. Newsholme, Department of Biochemistry, South Parks Road, Oxford. The closing date for applications is September 14, 1974. (693)

NATIONAL INSTITUTE FOR MEDICAL RESEARCH MILL HILL—LONDON

GRADUATE BIOCHEMIST required in the Division of Biophysics to assist in the research of enzyme structure and function. Experience in enzyme preparation and assay preferred. Salary on scale £1,650 to £2,343 p.a. plus £125 p.a. threshold agreements. Please apply, quoting ref: JTO/BP to J. H. Woodcock, Personnel Officer, National Institute for Medical Research, The Ridgeway, Mill Hill, NW7 1AA. Tel: 959-3666. (701)

BIRKBECK COLLEGE (University of London)

RESEARCH ASSISTANT IN PALAEOBOTANY

Applications are invited for a post of Research Assistant in Palaeobotany and Palynology. Honours degree in Botany required, ideally with experience in palaeobotanical methods.

Salary within range £1,686 to £2,412; appointment for up to three years, beginning October 1, 1974.

Further details and application forms from the Deputy Secretary, (N), Birkbeck College, Malet Street, London WC1E 7HX. Closing date August 31, 1974. (695)

UNIVERSITY OF BRITISH COLUMBIA DEPARTMENT OF PHARMACOLOGY

Two assistant or associate professors to be appointed by July 1, 1975:

- (a) one PHARMACOLOGIST, PhD and/or MD;
 - (b) one CLINICAL PHARMACOLOGIST, MD and PhD or equivalent plus specialty qualifications.
- Salary to be negotiated. Duties include teaching and research. Applications including curriculum vitae and the names of three referees to be sent to Dr. M. C. Sutter, Head, Department of Pharmacology, University of British Columbia, Canada, V6T 1W5, by December 1, 1974.

An Equal Opportunity Employer, M/F. (702)

CSIRO AUSTRALIA DIVISION OF ANIMAL HEALTH SYDNEY, N.S.W. RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: EXPERIMENTAL PATHOLOGY

General: The Division has three major laboratories—the Animal Health Research Laboratory, Parkville, Victoria; the McMaster Laboratory, Sydney, N.S.W.; and the Long Pocket Laboratories, Indooroopilly, Queensland. The appointee in this instance will be located at the McMaster Laboratory, the Divisional centre for studies into gastro-intestinal disease of which helminths of sheep and cattle constitute a major component.

Duties: To work on aspects of gastro-intestinal pathology with particular reference to the scouring diseases of young stock and enterotoxaemia in sheep and cattle. To collaborate and interact with scientists studying the pathophysiology of helminth infections and with helminth immunologists currently working at the McMaster Laboratory.

Qualifications: A degree in veterinary science or equivalent qualifications, and a Ph.D. degree in a relevant discipline or equivalent qualifications, supported by satisfactory evidence of research ability and experience in bacteriology.

Salary: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

Tenure: An indefinite or fixed-term appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 201/461, should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway, London WC2B 6BD.

by the 6th September, 1974.

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A. (700)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF ANIMAL PHYSIOLOGY BABRAHAM, CAMBRIDGE, CB2 4AT SCIENTIFIC OFFICER

required in the Director's Unit. Applicants should have a pass degree, H.N.C. or equivalent. The successful candidate will assist in an interdisciplinary research program involving the use of electrophysiology and histological techniques, bioassay of hormones and specialised care of experimental animals. Experience in one or more of these fields would be an advantage, but enthusiasm and adaptability are regarded as of equal importance.

Salary in the scale £1,592 to £2,675 according to qualifications and experience. There is a non-contributory Superannuation Scheme. Applications with full details should be sent to the Secretary of the Institute as soon as possible quoting reference D.U.2. (703)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF ZOOLOGY

A position exists immediately for a POST-DOCTORAL RESEARCH WORKER in mammalian cell mutagenesis to join a group working on the cell cycle. Applicants should have a Ph.D. and experience in cell culture techniques and mutagenesis; some biochemical experience would be useful. The post is funded by grants from the Cancer Research Campaign and will initially be for two years with the possibility of further support. Salary within the range £2,800 to £3,800 p.a. according to age and experience, and superannuation with the F.S.S.U.

Written applications giving the names of two referees and including a curriculum vitae should be sent to Dr R. T. Johnson, Department of Zoology, Downing Street, CAMBRIDGE CB2 3EJ. (709)

Senior Technician

£2346-£3147

Applications are invited from persons qualified to HNC or HND level and possessing relevant experience for the post of Head Technician in the Division of Bacterial Products in this Institute. The primary functions of the Division are to control, on behalf of the DHSS, the quality of all bacterial vaccines and antibacterial sera used in the U.K. This work is integrated with a related research programme.

The person qualified will be responsible for the smooth and effective operation of all technical services in the Division and will, in addition, undertake a defined aspect of the work under the supervision of a member of the Senior Scientific Staff.

Please apply, giving brief details (an application form will be sent to you) quoting reference 0035 to R.S. Dunn, Personnel Officer, National Institute for Biological Standards & Control, Holly Hill, Hampstead, London, NW3 6RB Telephone: 435 2232.

NIBSC

National Institute for Biological Standards and Control

(699)

NATIONAL COAL BOARD

Mine Geologists

Applications are invited for the post of Mine Geologist, each to serve 2 or 3 collieries in the East Pennine Coalfields.

The successful candidates will be responsible for recording geological information and participating in investigations into the effects of the geological environment on mining operations. The work will mainly involve underground duties.

Applicants should have an honours degree in Geology. Training in underground geological techniques will be given to the successful candidates.

Starting salary will be paid, in accordance with qualifications and experience, within the scale £2,345-£2,885.

Write for details to:—

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF ANIMAL PHYSIOLOGY
BABRAHAM, CAMBRIDGE, CB2 4AT
HIGHER SCIENTIFIC OFFICER

required in the Department of Applied Biology to work in a laboratory concerned with Animal Behaviour and Physiology. Minimum qualifications pass degree or H.N.C. and considerable laboratory experience preferably in one or more of the following subjects: physiology, experimental psychology, ethology. Salary in scale £2,461 to £3,371. The post is pensionable. A new modern superannuation scheme is being devised. Application forms and more details may be obtained from the Secretary of the Institute. Please quote reference B.A.4. Closing date August 25, 1974. (704)

UNIVERSITY OF MELBOURNE CHAIR OF ELECTRONICS AND COMMUNICATIONS

The University of Melbourne invites applications for the newly created Chair of Electronics and Communications, which is a second chair in the Department of Electrical Engineering. The appointee will be expected to develop teaching and research and to participate in departmental and faculty activities.

Salary: \$A19,614 per annum.

Further information about the position, application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment is available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **November 1, 1974.**

(707)

CONNECTIVE TISSUE RESEARCH

A post-doctoral position is available for a young biochemist to collaborate in studies on connective tissue catabolism. A first-class background is essential for this interesting and varied research programme and a knowledge of some aspect of connective tissue research would be an advantage. The position would be most suitable for someone who has recently finished his thesis.

The appointment is for one year in the first instance, and may be renewable. Salary on M.R.C. scale depending on qualifications and age. Write, with full curriculum vitae and the names of two referees to Dr. John J. Reynolds, Strangeways Research Laboratories, Wort's Causeway, Cambridge CB1 4RN. (705)

FELLOWSHIPS AND STUDENTSHIPS

THE POLYTECHNIC OF NORTH LONDON CHEMISTRY DEPARTMENT

POST-DOCTORAL RESEARCH FELLOWS

Applications are invited from suitably qualified research workers for two Research Fellowships, to work on the following projects, which are supported by the Science Research Council.

1. A Biogenetically-patterned Corrin Synthesis. Experience in synthetic organic chemistry would be an advantage for this project.
2. Structural Studies of the Coordination Template Effect of Metal Ions. Experience of X-ray crystallographic work is desirable for this project.

The appointments will be temporary, initially for two years. The salary scale is £2,151 by £90 to £2,421 and paid part-time teaching work may be available in addition.

Applicants should reply giving details of qualifications and experience, and the names of two referees to Dr A. P. Johnson (for post 1) or Dr. P. G. Owston (for post 2), Chemistry Department, The Polytechnic of North London, Holloway Road, London N7 8DB. (634)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

POSTS IN THE DEPARTMENT OF GENETICS

Several positions are available in the Department (Head: Professor W. Hayes, F.R.S.), for appointment as Senior Fellow, Fellow, Research Fellow or Postdoctoral Fellow, to initiate a programme of research on regulation and differentiation in lower eukaryotes. Applicants should have experience of biochemical as well as genetical methods. The department, with about twelve academic staff, is well equipped and has only research responsibilities. Current research topics include regulatory mechanisms in phage, bacteria and *Neurospora*; developmental genetics and transgenesis in plants; and evolutionary studies on bacteria and vertebrates.

Closing date: **September 14, 1974.**

FELLOW: DEPARTMENT OF GENETICS

Applicants should have special knowledge of, and expertise in, bacterial and phage genetics with particular reference to membrane biology.

Closing date: **August 30, 1974.**

Salaries: Salary on appointment to the posts will be in accordance with qualifications and experience within the ranges: Senior Fellow \$A14,724 to \$A16,921 p.a.; Fellow \$A10,771 to \$A14,704 p.a.; Research Fellow and Postdoctoral Fellow \$A9,002 to \$12,269 p.o. Current exchange rates are approximately \$A1=67p=US\$1.49.

Other Conditions: Tenure: Senior Fellow and Fellow for five years in the first instance with the possibility of extension to retiring age; Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years; Postdoctoral Fellow for not less than one year and not more than two years. Postdoctoral Fellows would normally have recently completed the Ph.D. degree.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation (where applicable) is on the F.S.S.U. pattern with supplementary benefits.

Travel expenses from overseas (except New Zealand) are not provided for posts at the level of tutor but assisted passage can be considered for a person offered appointment from the United Kingdom who intends to settle permanently in Australia.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (636)

LA TROBE UNIVERSITY

MELBOURNE, AUSTRALIA

RESEARCH FELLOW IN GENETICS AND HUMAN VARIATION

(one or two positions)

Applicants will be appointed for one or two years, with possible extensions up to a total tenure of three years. They will be expected to work in one of the areas of interest of the Department which include behavioural, cellular, ecological, human, microbial, population and quantitative genetics and cytogenetics. Enquiries may be directed to Professor P. A. Parsons, Chairman of the Department, in the University.

Salary: \$A7,545 to 2 by \$A292 to 3 by \$A291 to 4 by \$A479 to 5 by \$A478 to \$A12,352.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia 3083.

Applications close on **September 13, 1974.**

(529)

THE CITY UNIVERSITY DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

for work on the combustion and flammability of hydrocarbon mists. The Fellowship will be available for one year in the first instance, and the initial salary will be about £2,500. Further details may be obtained from Professor C. F. Cullis, Department of Chemistry, The City University, St John Street, London EC1V 4PB, to whom applications (together with the names of two referees) should be sent before August 31, 1974. (606)

European Molecular Biology Organization (EMBO)

Short- and long-term fellowships in molecular biology

The European Molecular Biology Organisation intends to award to scientists working in laboratories within the European area both short-term (from a few days to several weeks) and longer-term fellowships for collaborative research or advanced training in molecular biology.

The Short-term Fellowships are to support visits to other laboratories for the purpose of carrying out experiments with special techniques or of other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

The Long-term Fellowships will usually be for a period of one year, but applications for renewal will be considered. They will be awarded upon individual application, at the "junior" level to promising young research workers who may then spend prolonged periods in other laboratories working under the guidance of leaders in the field of molecular biology. At the "senior" level, they may be awarded to enable established research workers to gain experience in new approaches and new problems. Upon application by European Institutions fellowships at the "senior" level may also be awarded to specialists who can assist in the initiation and development of research programmes in the sponsoring Institution. Such "sponsored" awards may be made to established workers at all stages of their career beyond the postdoctoral stage.

Application forms and further details may be obtained from Dr J. Toozé, Executive Secretary, European Molecular Biology Organisation, 6900 Heidelberg 1, Postfach 1022.40, Germany.

(521)

UNIVERSITY OF LEEDS

DEPARTMENT OF INORGANIC AND STRUCTURAL CHEMISTRY

Applications are invited from suitably experienced chemists or physicists for a post of **POSTDOCTORAL FELLOW** to investigate the mechanisms of **FAST IONIC TRANSPORT IN INORGANIC SOLIDS** primarily by utilising the radioactive tracer technique supported by possible evidence of defect structure from high temperature diffraction measurements, and interpreted in conjunction with the resonance studies already being undertaken.

S.R.C. funds are available for 2 years from October 1, 1974; salary on the scale £2,118 to £2,412 plus F.S.S.U., depending on age and experience. Further information from Dr A. T. Howe, Dept. of Inorganic and Structural Chemistry, The University, Leeds LS2 9JT, to whom applications, including the names of 2 referees, should be sent as soon as possible. (608)

UNIVERSITY OF LIVERPOOL

UNIT OF REPRODUCTIVE BIOLOGY

Applications are invited from honours graduates who are interested in physiological research and who have a degree in either Physiology or Zoology, for a graduate studentship in this Unit.

Applications should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/276164/N. (638)

UNIVERSITY OF MANCHESTER

Department of Geology
in collaboration with

Selection Trust Ltd.

N.E.R.C. C.A.S.E. Studentship

Applications invited for a studentship tenable from September to work for a higher Degree on the relationship between mineralisation and geological setting in Carboniferous rocks. Applicants should hold an Honours Degree or equivalent qualification in an appropriate discipline; some mineral exploration experience an advantage. Applications with curriculum vitae and names of two referees as soon as possible to the Secretary, Department of Geology, The University, Manchester M13 9PL, from whom further details are available. (665)

UNIVERSITY OF WESTERN AUSTRALIA PERTH

UNIVERSITY RESEARCH FELLOWSHIPS (POSTDOCTORAL)

Five Research Fellowships will be offered, to be taken up as soon as possible. Appointment will be for one year in the first instance with the possibility of renewal for a second year. The Fellowships could possibly be renewed also for a third year, but in competition with any new applications. They will be tenable in the following academic departments for work in the areas stated below:

Italian: Italian High Renaissance, c. 1480-1520 (1600).

Philosophy: Locke.

Economics: Economic Theory.

Politics: Evaluation of federal-state politics in government in Australia.

Mechanical Engineering: Environmental Fluid Mechanics OR Control Systems.

Electrical and Electronic Engineering: Integrated Optics—Optical Communications.

Botany: Plant Fine Structure.

Psychology: Child Development OR Vision.

Biochemistry: Mechanisms of Lactation and

Parturition OR Developmental Biochemistry.

Microbiology: Antigenic Variation in Viruses.

The Fellowships are intended primarily for Ph.D. graduates (normally from other universities), or those with equivalent qualifications, who by publication and in other ways have demonstrated significant research capability. Initial salary will be within the range \$A7.54 to \$A9,002 p.a., and appointees may in certain circumstances be considered for admission to an F.S.S.U. superannuation scheme. Fellows may be given the opportunity to participate in teaching. An overseas appointee would be entitled to appointment expenses of up to \$A1,000 and an appointee from within Australia to fares for self and spouse.

Applications in duplicate setting out full personal particulars, qualifications and experience, and describing the details of the research interest should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by **September 30, 1974**. Candidates should request three referees to write immediately to the Staffing Officer. (645)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF BIOCHEMISTRY
RESEARCH STUDENTSHIP IN PHYSICAL
BIOCHEMISTRY

Applications are invited from honours graduates in Chemistry and Biochemistry for studies on the physical biochemistry of enzymes. The nature of the award will be equivalent to an S.R.C. Studentship and the candidate will be able to register for a Ph.D. degree.

Applications giving curriculum vitae and the names of two referees should be sent by August 31st to Superintendent, Department of Biochemistry, Tennis Court Road, Cambridge CB2 1QW.

(X664)

BRUNEL
UNIVERSITY

(Department of Polymer Science
and Technology)

Applications are invited for the CEMENTATION CHEMICALS RESEARCH STUDENTSHIP from graduating and recently graduated chemists or material scientists.

Work will be in the field of solid polymer characterisation but aimed at products of civil engineering end use.

This studentship is unique in that very close liaison will be encouraged between the student/University and the industrial sponsor.

The work, initially for one year, will lead to the degree of M.Phil. The salary of £900 p.a. will be paid. In addition fees and reasonable expenses will be met.

Candidates—Male or Female should apply to:—

Mr G. R. Southern,
BRUNEL UNIVERSITY
Department of Polymer Science,
Kingston Lane,
Hillingdon, Uxbridge.

(708)

THE MEDICAL COLLEGE OF
ST BARTHOLOMEW'S HOSPITAL
WEST SMITHFIELD, LONDON EC1A 7BE
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH
FELLOWSHIP

for work of the Mechanisms of Action and Control of Thiol Enzymes.

Applications are invited for the above post tenable for 2 years from October 1, 1974, from graduates with a Ph.D. and experience in kinetic and/or fluorescence work with enzymes.

The successful applicant will work with Dr K. Brocklehurst on the reactivity characteristics of thiol groups in enzyme catalytic, regulatory and reporter sites. Use will be made of novel reagents tailor-made by Professor H. Suschitzky's groups in the University of Salford. Salary on the Scale £2,118 to £2,412 p.a. plus £213 London Allowance. Curriculum vitae and names of 2 referees to The Secretary of the Medical College, quoting reference 669.

(639)

UNIVERSITY OF EDINBURGH
RESEARCH FELLOW
DEPARTMENT OF THERAPEUTICS

A Research Fellow with or without medical qualifications is required for a research project for 2 years on cancer immunology relating to the immunological status of patients with lung or breast cancer and the assessment of immunological tests for cancer under the direction of Dr. W. J. Irvine, Immunology Laboratories, Department of Therapeutics, Royal Infirmary and 2 Forrest Road, Edinburgh.

The salary scale is for non-clinical or clinical lecturers (£2,118 to £3,474) according to age, qualifications and experience.

Applications, together with the names of two referees, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL. Please quote reference number 5042.

(694)

AUSTRALIAN NATIONAL
UNIVERSITY

Applications are invited for appointment to the following:

RESEARCH SCHOOL OF BIOLOGICAL
SCIENCES

PROFESSORIAL FELLOWSHIP
Department of Neurobiology

The Department (Head: Professor G. A. Horridge) has an active programme of research in the neural basis of behaviour and perception in lower animals, mainly insects and crustacea. Applicants should be capable of a strong research programme in an aspect of neurobiology which is either complementary or supplementary to the present interests, which include: (a) mechanisms of arthropod vision; (b) growth and regeneration of insect nerves; (c) control of movement in crustaceans; (d) biochemistry of insect neurons; (e) insect sound production and hearing; (f) establishment of connections between nerve cells.

The University is looking for a man with an ambitious project who finds himself restricted by lack of assistance, research time or equipment. Vertebrate neurobiology is not excluded. The position is tenured, with opportunity to train graduate students.

Closing date: **September 21, 1974.**

JOHN CURTIN SCHOOL OF MEDICAL
RESEARCH

SENIOR RESEARCH FELLOW,
FELLOW OR SENIOR FELLOW IN
PHYSICAL BIOCHEMISTRY

Appointment will be in the Department of Physical Biochemistry (Head: Professor L. W. Nichol). Applicants should be interested in setting up a small research group to carry out theoretical and experimental studies involving biological macromolecules or systems. The Department is well equipped for the study of macromolecular properties in solution; the fields of nuclear magnetic resonance spectroscopy and X-ray crystallography will not be pursued as major interests within the Department in the near future.

Closing Date: **October 21, 1974.**

SALARIES: Salary for a Professorial Fellow is \$A18,131 p.a. Salary on appointment to the other post will be in accordance with qualifications and experience within the ranges: Senior Fellow \$A14,724 to \$16,921 p.a.; Fellow \$A10,771 to \$14,704 p.a.; Senior Research Fellow \$A13,163 to \$15,548 p.a.. Current exchange rates are approximately \$A1: 67NP: \$US1.49.

OTHER CONDITIONS; tenure: Professional Fellow to retiring age (65 years); Senior Fellow and Fellow for five years in the first instance with the possibility of extension to retiring age; Senior Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should apply to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (686)

NATIONAL RESEARCH
DEVELOPMENT COUNCIL
N.R.D.C. FELLOWSHIP

Applications are invited for an N.R.D.C. Fellowship. The successful candidate will work under the direction of Dr K. Jewers at the Tropical Products Institute on the isolation and transformation of biologically active compounds from tropical plants. The Fellowship is tenable for one year in the first instance with the possibility of renewal subject to satisfactory progress being made.

Applicants should have a degree or equivalent in chemistry plus at least two years postgraduate experience.

Salary in the region of £2,689 per annum plus an annual leave allowance of 22 days.

N.R.D.C. RESEARCH ASSISTANTSHIP

Applications are also invited for an N.R.D.C. Research Assistantship. The successful candidate will work under Dr K. Jewers at the Tropical Products Institute on the pharmacology of biologically active constituents isolated from tropical plants. This post is also tenable for one year in the first instance with the possibility of renewal for a further period subject to satisfactory progress being made.

Applicants should have a degree or equivalent in pharmacology. Salary £1,820 to £2,040.

Application forms for both these posts from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 8DB. (635)

Studies in History and Philosophy of Science

Studies in History and Philosophy of Science is a quarterly journal which analyses the genesis, evolution and logic of scientific thought. It attempts to unite historical and philosophical approaches to science.

Recent papers include:

Maxwell's Methodology and his application of it to Electromagnetism, A. P. Chalmers. **The Astronomy of Eudoxus: Geometry or Physics?**, Larry Wright. **Conceptual Structures and Scientific Change**, Garry Gutting. **Whewell's Theory of Scientific Language**, Morton L. Schagrin. **Speculation in Physics: The theory and practice of Naturphilosophie**, Barry Gower. **Feyerabend and Galileo: the interaction of theories, and the reinterpretation of experience**, Peter K. Machamer. Edited by Gerd Buchdahl, Reader in History and Philosophy of Science, University of Cambridge and Professor L. L. Laudan, Chairman, History and Philosophy of Science, University of Pittsburgh. Published by Macmillan Journals Limited.

Annual Subscription £8.50 (£9.50 U.S.A. and Canada). Prices applicable only to orders starting before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon — differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Recent papers include:

Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wylie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues**, G. Harris. **The principle of sequential dependence in cellular differentiation**, P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpêtrière, Paris.

Annual subscription £20 (£22.00 U.S.A. and Canada). Prices applicable only to orders started before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Bringing automatic chemistry down to size

The ABA.100 will provide your laboratory with a fully automatic discrete and highly flexible clinical chemistry analyser, which combines high workload capacity with high resolution spectrophotometry, both U.V. and visible.

Speed

100 to 150 samples per hour.

Ease

Automatic processing, data handling and print out.

Convenience

Kinetics and end points, 30° or 37°C,* unit conversions, increasing or decreasing absorbance measurement at the flick of a switch.

Accuracy & Precision

C.V.'s typically better than 2% in the normal range.

Temperature maintained to within $\pm 0.1^\circ\text{C}$.

Automatic reagent blank correction.

Data-calculations and conversions performed by integral mini-computer.

Conversion directly into IU/l or mgm.

Automatic warning of *non-linear rate reactions*.

Economy

Saves substrate—uses as little as 250 μl .

Saves serum—uses as little as 5 μl .

Saves time—30 glucose in 10 minutes.

Saves space—only 4 cubic feet of bench space.

* 25°C AVAILABLE.

UNIVERSITY OF READING
INSTITUTE OF GEOLOGICAL SCIENCES

A N.E.R.C.-funded C.A.S.E. studentship is available for a project concerning the effects of weathering on the physical and chemical properties of clays. The work, which will be submitted for a higher degree, is to be carried out partly in the Reading Geology Department and partly with the I.G.S. Engineering Geology Unit. Apply immediately to Dr R. Till, Geology Department, University of Reading, Whiteknights, Reading RG6 2AB. (Ref. M.N.40). (644)

REGIONAL NEUROLOGICAL
CENTRE,
NEWCASTLE UPON TYNE

Post-doctoral biochemists required for research work on biochemical aspects of neuromuscular disease. The posts are Research Associateships of the University of Newcastle upon Tyne and will be for one year in the first instance. Salaries will be at or near the bottom of the University Lecturers' scale. Experience in protein chemistry, enzymology, subcellular fractionation, and radio-active tracer techniques will be an advantage. Applications (with two referees) should be sent to Dr. R. J. T. Pennington at the Regional Neurological Centre, General Hospital, Newcastle upon Tyne, NE4 6BE, from whom further information may be obtained (Telephone: Newcastle 3-8811, Ext. 483). (681)

THE JACK CHARRINGTON
MEMORIAL FELLOWSHIP 1974/75

The closing date for applications for the above fellowship, as advertised in July 11, 1974 issue of this Journal, has been extended to August 31, 1974. (683)

SUBSCRIPTION –
REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of a twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

THE NATURE OF THE STRATIGRAPHICAL RECORD

Derek V. Ager

Based on Professor Ager's observations in many parts of the world, this book takes a new look at the earth's history as recorded in the rocks. Mingling scientific comment with academic humour he presents a series of original and controversial propositions and challenges some of the assumptions that limit the views of many stratigraphers to their own particular areas of interest. His arguments are well illustrated with diagrams and photographic plates and though primarily for geologists, this book will also be of interest to teachers of physical geography.

£2.95

RECENT EARTH HISTORY

Claudio Vita-Finzi

Dr Vita-Finzi demonstrates the advantages of basing earth history on quantitative dating in its own right, rather than as an appendage of stratigraphy. Original and clearly written, the book may provoke disagreement but it is logically argued and will stimulate discussion among students and teachers.

£3.00, paperback £1.50

Macmillan

Water, Soil and the Plant

E. J. Winter

Science in Horticulture series

General Editor:

Professor L. Broadbent

The first simple account of the circulation of water through soil, plant and atmospheres. The biological and physical phenomena involved are carefully discussed in relation to their horticultural significance.

PERSPECTIVES IN BIOMEDICAL ENGINEERING

Edited by R. M. Kenedi

Contains the proceedings of an international symposium which was held at the University of Strathclyde in June 1972, topics discussed ranging from clinical measurements and instrumentation to prosthesis and artificial organs.

'As a lesson to all concerned with research, these papers demonstrate the areas of research most likely to produce greatest relief of human suffering and most likely to produce results. The multidisciplinary approach is obviously being made to work, and we should be thankful that at least one branch of medical research has left its ivory towers and actually solves real problems. Certainly this volume should be on the bookshelf of every hospital library' —

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Cambridge : its manpower and money

THE University of Cambridge, in an annual gesture calculated to bring some relief to an editor beleaguered in the August silly season when government and universities vanish, has just released a small mountain of statistics. Two issues of the *Reporter*, issued on August 7, deal with student numbers and with sponsorship of research within the university. At ten pence, the pair provide a remarkably detailed profile of a university which has often claimed, with some justification, to be particularly distinguished in the sciences.

For several years Cambridge's undergraduate numbers have remained relatively constant. There is at the moment still a swing towards admitting more women but total numbers of students rose only 0.5% last year. On the other hand the numbers of those applying to enter is falling rather rapidly as Table 1 (compiled with the help of a *Reporter* of last year) shows. At present roughly half of those who apply get accepted, not long ago it was barely a third.

Table 1 Trends (percentages) in student numbers from 1973 entry to 1974 entry.

	Applications	Acceptances
English	-18	+3
History	-7	+3
Modern languages	-18	+2
Law	+5	+4
Mathematics	-9	+2
Natural sciences	-16	-10
Engineering	-8	+2
Medical sciences	-3	-1

The swing away from science is manifested in an interesting way. If we can assume certain standards of rationality in the selection procedure we must conclude that the swing is more in quality of student than in quantity of applications. All of this is well known on a national and international scale, and those in provincial universities can be excused a wry smile that Cambridge is beginning to feel the breeze that is a gale in their own laboratories. Once the trend has started downwards, though, the question must be whether the resources of Cambridge are capable of reversing it. The news can only be good for teachers of science in schools, getting increasingly used to being courted by other universities and now, at long last, to be wined and dined at High Table for the favours of their shrinking brood.

The other report puts together expenditures, by sources outside the university, of research projects for the financial year 1972-73. At the detailed level it is a delight. The Department of the Environment spent £150 with Applied Mathematics of "Effect of wind on people". The

Veterinary School received £522 worth of equipment and materials from "Broilers-various". The Science Research Council cheerfully gave £88,651 for "Observational and theoretical astronomy" but needed the justification of "Spectroscopic studies of some metal deficient and some strong line *g* and *k* type stars" before forking out another £40. And what does one make of the Ministry of Defence's total expenditure—£114,000 by our addition, £14,000 by the *Reporter's*? Misprint or deceit?

Table 2 Sources of research funding 1972-73.

	£
Government bodies	2,125,000
Charities, trusts, foundations	480,000
Overseas bodies	98,000
Four industries*	81,000
The rest of British industry	60,000
<i>Studentships and capital expenditure excluded</i>	

* Mullard, Beecham, Rolls-Royce, Tobacco Research Council.

Table 2 brings together the sources—our interpretation and our addition. It is worrying, to say the least, that the university has such a restricted financial relationship with industry. Here, surely is a pointer to the mutual suspicion between industry and academics which is such a disagreeable feature of British scientific life. And here, also, is a good place from which an improvement in relations could grow. It would be quite wrong to point a blaming finger specifically at either side, but perhaps when the schoolteachers have had their meal at High Table there might be something left over for industrialists. If not, Cambridge's days as an outstanding university could be numbered.

100 years ago

M. MAREY has recently published the results of experiments undertaken to determine by the graphic method what is the true movement of the legs in walking. His results prove convincingly that the brothers Weber were wrong in assuming that the oscillation of the leg which is not in contact with the ground is the same as that of a pendulum; for when it is represented on a uniformly moving plane, the line drawn is a straight and not a curved one. The movement of the suspended foot is therefore uniform, depending on muscular action, in combination with that of gravity.

From *Nature*, 10, 306, August 20, 1874.

The legacy of the Nixon years

A few hours before he announced his resignation as President of the United States, Richard Nixon vetoed the appropriations bill for the Environmental Protection Agency because he considered it to be inflationary. It was a symbolic last act for an Administration which spent a good deal of time doing battle with Congress over spending priorities. Colin Norman discusses how, for that small section of the population known as the scientific community, which has often been caught in the middle of the budgetary battle, Nixon's last veto was a reminder of what has passed and probably a taste of things to come.

IN his five and a half years in the White House, Nixon did not exactly win the undying support of scientists for his handling of scientific affairs. In fact, throughout his Presidency, cries of alarm from parts of the scientific community have been clearly audible above the background grumblings from most of academe. Among other things, the departed president and his lieutenants have been accused of plunging science into a financial crisis, of relegating some scientific disciplines to second place in the world pecking order, of failing to foresee situations in which science and technology could have been marshalled to help out (such as the energy crisis) and even of ignoring science completely.

The record, however, is a good deal better than many of the criticisms allow, and a good case can be made for the argument that some of the disquiet in the scientific community has its origins in events which took place well before Nixon set foot in the oval office. And it can equally well be argued that many of the science policies and institutional arrangements laid down by President Nixon will survive long after his departure.

Underlying most of the criticisms of Nixon's stewardship of the scientific enterprise is the fact that federal expenditures on science and technology during the past five years have increased at a rate barely sufficient to keep pace with inflation, and in some cases funding has even declined. On top of that, the Administration has gone for some of the scientific community's most cherished programmes, of which biomedical training was perhaps the most prominent. And the final straw

came early last year when Nixon announced that he no longer needed a full-time science adviser in the White House, so he abolished that post along with the Office of Science and Technology and assigned some of its duties to the Director of the National Science Foundation.

Thus, the Nixon Administration's policies were clearly not designed to bring joy to the country's science and engineering laboratories. Nevertheless, scientists and technologists have fared rather better than their colleagues in many other disciplines, and the federal budget for science and technology, which stands at nearly \$19,000 million (\$4,600 million more than it was five years ago) is immense by any measure.

When the Nixon Administration came to power, the unquestioned growth of the science budget which took place during the Eisenhower and Kennedy Administrations had already come to a virtual halt. Thus, the first couple of years of so of Nixon's tenure were marked by painful adjustment from a period of burgeoning growth in science budgets to a period of almost static funding. One consequence was that the job market for scientists rapidly became very tight just when record numbers of scientists were emerging from the academic pipeline, a situation which did little to enhance the new Administration's standing in the eyes of the academic community.

The Administration's response was to cut back on funding for programmes designed to increase the supply of scientists and technologists. In 1971, for example, the proposal was made to eliminate the National Science Foundation's institutional support programme

and to phase out its graduate training programmes. Since those two items were highly cherished sources of funds for universities, which were then facing huge financial deficits, the Administration's academic support slipped a few more notches.

But the budget announced in January 1971 represented, for the first time since 1968, a real increase in federal support for research and development. This was carried through with another boost for science and technology in the budget announced a year later. But, in January 1973, just after his re-election, Nixon slammed the brakes on public expenditure and withheld considerable sums of money promised in the pre-election spending spree, with the result that funding for science again took a hammering. Nixon's support in the scientific community hit another low.

Finally, the budget announced just six months ago promised another round of increases in research and development expenditure, chiefly for the development of energy resources and for the Department of Defense.

The overall pattern of expenditure has therefore been one of stagnation, growth, cutbacks and growth—a situation which has not been conducive to university planning, and which has been unsettling for those who are forced to depend on the government for research grants. Whether or not the fabric of science in the United States has been damaged in the process, is, however, open to question.

The upshot of this slow and sporadic growth in the science budget has been to force a number of painful priority decisions in the basic sciences, as, for example, in space research where a number of promising satellite missions have been dropped, the High Energy Astronomy Observatory has been considerably scaled down in cost and performance and other missions have been deferred to accommodate development of the shuttle in a tight overall budget.

Similarly, particle accelerators have been shut down in order to accommodate the rapid growth in the budget of the National Accelerator Laboratory, and many research grant applications which have been designated as scientifically worthwhile by peer review groups at the National Institutes of Health have gone unfunded for lack of money. In the days of burgeoning growth, such painful choices probably not have been needed.

It has been in the biomedical science community, however, that the cries of anguish over the Administration's science policies have been loudest, and once again, the problems have been

Ford: inherits unhappy science community

White House science adviser
Guyford Stever (left)
and Edward E. David, jun. (right).

exacerbated by a painful transition from periods of rapid growth to stagnation.

Superimposed on the situation, however, is the fact that in the past three years two highly publicised crusades—against cancer and against heart disease—have been launched and enthusiastically supported by both Congress and the Administration. The result has been that the budgets of the National Cancer Institute and the National Heart and Lung Institute have been allowed to grow relatively rapidly, while other NIH institutes have been held back so that many are now receiving less money than they got in 1968. Moreover, biomedical scientists both at NIH and in the Universities have complained bitterly that the Administration has been trying to run the cancer and heart programmes like NASA-style operations to land men on the moon by highly targeted research programmes which have drawn money away from basic research.

On top of all those complaints, the biomedical community has been upset by repeated vetoes by President Nixon of the appropriations bills for the Department of Health, Education and Welfare, which have held up funds for months, and which have kept funding at the levels proposed by the Administration rather than at the more generous levels approved by Congress.

These funding decisions and policy changes have not, however, been taken entirely in a vacuum, for Mr Nixon has also made substantial changes in the science policy machinery in the top echelons of the federal government. In fact, it is those changes which have done most to upset the elder statesmen of the scientific community.

When he arrived in the White House, Nixon inherited an extensive science policy apparatus whose origins dated back to the second World War, but when he departed last week, virtually none of it was left intact.

On the President's immediate staff was a science adviser, and a small policy office called the Office of Science and Technology which provided him with staff support. Lines to the scientific community were kept open by means of the President's Science Advisory Committee, chaired by the science adviser, and filled with a raft of luminaries from the universities. Nixon appointed Lee A. DuBridge, President of MIT as his first science adviser.

DuBridge and the Office of Science and Technology never became a powerful force in the Nixon White House, however, partly because President's

Science Advisory Committee took a number of stands on military matters which were in direct opposition to the Administration's policies, and partly because the rest of the White House just wasn't interested. And, as the influence of the science apparatus waned, the power of the New Office of Management and Budget (OMB) increased, so that it is now the focal point through which White House policy is conveyed to the departments and agencies. It wields tremendous power through the budgetary process.

DuBridge was eventually succeeded by Dr Edward E. David, jun., an engineer from Bell Labs, who departed in January last year after trying to interest the rest of the White House in science, with little success. Within two weeks of David's departure, Nixon scrapped the Office of Science and Technology, the post of Science Advisor to the President and the President's Science Advisory Committee, and designated the Director of the National Science Foundation, Dr H. Guyford Stever, as science adviser to the White House.

Stever has since established in NSF a science policy office and an energy policy office, and he has been given a budget three times larger than that of the defunct Office of Science and Technology. He has also established lines to OMB, and is generally credited with doing a commendable job, given the limits to his power.

The changes irked many scientists, however, who felt that science had been downgraded in national affairs, and many people have also criticised the fact that Stever has specifically been given no mandate to advise on military technology. In response to such complaints, Dr Philip Handler, President of the National Academy of Sciences, established recently a special

blue ribbon panel under the chairmanship of Dr James Killian, Eisenhower's first science adviser, to look into the workings of the present science policy apparatus.

Not surprisingly, the Killian panel recommended that a science advisory council should be re-established in the White House, and that the present arrangement is unsatisfactory since Dr Stever, being head of a small science agency, is not in a strong enough position to orchestrate the vast federal science bureaucracy. Since there was absolutely no chance that Nixon would reinstate the post in the White House, the recommendations were clearly aimed at his successor.

Thus, President Gerald Ford has inherited an unhappy scientific community, a strong feeling among the scientific establishment that science should be reinstated in the White House, and a host of problems such as the energy crisis and food shortages which will require large injections of science and technology.

Clearly, the science policy apparatus is not going to be one of Ford's immediate concerns, and little change can be expected in the short term. Ford himself has said that his immediate concern is to curb inflation, however, and that, indirectly could have a bearing on science.

Ford is a self-confessed fiscal conservative, believing in balanced budgets and decreased federal expenditures. Since only a relatively small proportion of the federal budget can be decreased—the vast majority of the budget is for such items as salaries, pensions and welfare payments which cannot be tinkered with—and since science expenditures mostly fall into the controllable category, the pressure on the science budget is unlikely to decrease under President Ford.

Two approaches to scientific aid for disaster areas

Scientists and nonscientists alike are becoming increasingly aware of the need for science to be 'relevant'. In human terms, perhaps the most important applications of science are to the problems facing the less developed parts of the world, and the need for relevant science can be seen most clearly at times of crisis—such as the recent floods in Bangladesh. But how effectively is science being used in such situations? John Gribbin and John Wilson have been looking at two contrasting approaches to these problems.

ESTABLISHED charitable organisations such as Oxfam are making increasing use of science and technology in their work; it is becoming accepted that provision of food to survivors of a disaster is no more than a temporary solution to any problem, and that famine and disease can only be prevented by more fundamental help. But still, only a tiny fraction of Oxfam's income, for example, is spent on research — although that small budget seems to be used remarkably effectively.

Among projects Oxfam is working on are:

- A completely new sewage disposal system which can be flown straight to disaster areas and is, according to Oxfam, cheap, simple and easy to erect.
- A new building technique to provide rapid emergency housing after an earthquake, flood or other catastrophe.
- An investigation of bicycle 'pedal power' in the poorer countries.

These are all projects with a sound scientific pedigree. The sewage scheme, for example, required fundamental research on the biology of the cholera vibrio. But money allocated by Oxfam to such research was only £3,000 in 1973, out of a total 'income' from public donations of £4.2 million, more than 80% of which was spent overseas.

The Deputy Director of Oxfam, Mr Guy Stringer, explains that the best use is made of this £3,000 by using Oxfam money only to prime the financial pump of a project. Once a plan has shown potential, Oxfam seeks help from other sources. This falls into line with the organisation's avowed policy

of spending as much of the public's money as possible 'over there' rather than on research at home. And the people and firms that Oxfam approaches are eager to help. "They have never refused us", says Mr Stringer.

Oxfam undoubtedly benefits enormously from this goodwill; but part of its success must surely lie in the simple direct approach which it adopts. The charity first became interested in sanitation schemes as a result of its experience of the refugee camps in Bengal during the Indo-Pakistan conflict of 1971. Oxfam workers there realised that most of the relief effort was being spent on the treatment of diseases arising from the insanitary conditions within the camps. Even so, this preventive medicine was often ineffective—particularly against cholera.

At first Oxfam simply tried to contain the excrement and other wastes of the refugees. It found that one possible container (a 30,000 gallon collapsible fuel tank belonging to the RAF) provided almost instant anaerobic conditions. From that discovery sprang the idea of destroying the cholera and dysentery bacteria anaerobically.

As no one knew the viability of *Vibrio cholerae* in anaerobic sewage, Oxfam asked Mr Barry Lloyd of the University of Surrey to find out. To keep costs as low as possible, Mr Lloyd presented the project to two final year students as the topic for their degree theses. Although each thesis 'cost' about £800, Oxfam paid only a tenth of this for the results.

The survival of the vibrios was found to depend on the temperature of the sludge and the proportions of solid matter in it. Vibrios were usually eliminated after 7 days at 37°C but at 25°C took 12 days to disappear. Once Oxfam had an estimate of how long the sewage should be retained in anaerobic conditions, it was able to seek the advice of the Water Pollution Research Laboratory at Stevenage, and the University of Loughborough on the general layout and hydraulics of the unit. The Plastics Research Group at the Atomic Energy Research Establishment, Harwell, designed a mould for a cheap stackable plastic squatting unit—the Asian equivalent of a toilet seat.

Mr Jim Howard, Oxfam's Industries Officer, emphasises the importance of

this squatting unit. Produced now for a matter of shillings, they replace heavy vitreous china items that cost about £50.

The sanitation package on which Oxfam has now decided consists of two or three large butyl rubber tanks holding some 4,500 gallons each, connected in series to a group of 20 squatting units. During October, a team from Oxfam will be taking an example of each unit to Bangladesh. With the cooperation of the Cholera Research Laboratories in Dacca, the two-bag unit will be tested on hospital effluent known to be rich in cholera bacteria and the three-bag system will be set up in a Bihari refugee camp to assess its impact on an existing community.

Even including the cost of this visit, Oxfam says it has spent less than £1,500 on the entire sewage project. Once the scheme was underway the Leverhulme Trust provided a grant of £19,000 and the British Government gave £6,500. The charity holds British, United States and Canadian patents on the system so it may still recoup what little it spent. With the addition of antifreeze the technique might be adapted for use in the Arctic or Antarctic.

The sanitation scheme is probably the most ambitious technical project that Oxfam have tackled and it typifies the organisation's direct approach to disaster relief. In the same vein, Oxfam is pioneering a building technique which it hopes will provide warm weather-proof shelters quickly and cheaply. Polyurethane foam is sprayed on to the inside of a lightweight aluminium mould. When the foam hardens, the mould is removed leaving a house with approximately 70 square feet of living space.

The mobile factory to spray the foam costs about £4,500 and Oxfam claims that the chemicals needed for one house may be bought for £30. Polystyrene granules are cheaper—and are rather more fire resistant—but the apparatus needed to steam them into place is six or seven times as expensive as the polyurethane apparatus. In September, Oxfam will be training two volunteer teams in the spray building technique.

In many underdeveloped countries a great proportion of the labour force—as much as 15% in some cases according to Mr Howard—spends its time moving water for irrigation. Oxfam is now trying to develop a portable

*Native huts, Oxfam style.
An aluminium shell is lowered into
place (left) and removed after serving
as a mould (right).*

water pump that could be powered by pedals in the same way as a bicycle. It is also investigating this use of pedal power to drive simple winnowing or grinding machines. With Mr Stuart Wilson, of the University of Oxford, it is developing a superior rickshaw, and a four wheel drive pedal platform or 'Pedalrover' which could carry half a ton across country; Zambia has already expressed an interest in this idea.

Oxfam does not always design its schemes for its own use. In 1971 it began a project to turn Britain's surplus potato crop and skimmed milk into a balanced emergency diet. Although Oxfam persuaded Cadbury Schweppes to let it use their powdered potato production lines at cost price it still spent £6,250 of its own money. Mr Howard feels that since Oxfam's new food is now accepted by the World Food Programme, it is up to the government to use the recipe when and if a surplus occurs again.

But Oxfam is not without its critics. Some people have expressed concern, for example, that any temporary housing provided after a disaster might remain occupied when conditions returned to normal, degenerating into instant slums. Oxfam admits that further work is needed to determine an optimum spacing of such units to minimise the fire hazard while housing as many people as possible—but it is fundamental to their philosophy that such housing is needed, although a case can be made that in many places, such as Bangladesh, the local population already possesses both the skills and the material needed for the rapid erection of cheap lightweight shelters.

At a more fundamental level, questions might be asked about whether such organisations as Oxfam are in fact the best bodies to organise scientific aid for disaster situations. The point is debatable; but it is true that Oxfam is not run by scientists, and that its scientific activities are still very much an appendage to the main work. So it is interesting that a group of London-based scientists is trying just the opposite approach. The London Technical Group (LTG) is a group of scientists from various disciplines which is looking at problems of disaster relief solely from the scientific and technological point of view.

The most widely available tangible product from the group so far is an

annotated bibliography of papers relating to *Disaster Technology* (LTG, 55 Evelyn Gardens, London; 1974). This typifies one aspect of the group's activities to act as a clearing house for relevant information and, hopefully, to ensure that such information does not disappear from the general awareness. Members of the group say that they have been astonished at how often 'new' ideas turn out to have been presaged years or even decades ago. They cite the example of the compression effects which cause internal injuries in victims pulled from collapsed buildings and have been "discovered" after almost every major earthquake affecting built up areas. In fact, they say, these problems were thoroughly investigated more than three decades ago, when many people were trapped in collapsing buildings during the mass bombing of the Second World War.

But the LTG is not just concerned with collecting and distributing information. Members of the group (now some 30 strong) see the LTG as something of a centre of expertise in terms of field experience of disaster and famine situations, eager to hire out their skills to anyone who can use them.

The opportunity for scientists with such expertise to meet regularly and discuss problems provides the third string to LTG's bow, as a 'disaster think tank'. Such ideas as mixing dried skim milk with oil to form a drinkable and nutritious emulsion (with the addition of appropriate substances to make it palatable) and an emphasis on rugged simplicity for all field equipment emerge from these meetings. Individual field trips made by members of the LTG have provided the essential training in

basics which encourages the group to think that it now has the experience to, say, carry out surveys of nutritional problems on behalf of governments or other bodies, who would put up the money and collect the results on a contractual basis. These trips also, of course, provide valuable information in their own right. Mr John Rivers, a member of the LTG, has just returned from Ethiopia, where he carried out a nutritional survey with Dr John Seamen as part of a UNICEF project, partially funded (to the tune of £1,000) by Oxfam. It seems from this work that the general feeling that protein deficiency may not be the greatest nutritional problem in famine areas may well be correct; the normal food of the nomads in Ethiopia includes milk, cereal and a little meat. In the present famine situation they are forced to eat other foods, such as beans. But there is no evidence that the quality of these foods is inadequate, whatever the problems of finding enough food; and this means that any emphasis on protein supplements as a high priority in famine relief is wrong, at least in this case.

It remains to be seen whether any charity or other organisation will jump at the opportunity of hiring the LTG team of scientific specialists as a group to do this kind of work, or whether the LTG will continue simply as a collection of concerned scientists devoting their spare time to efforts aimed at improving the way science is used to combat disasters. The approach they advocate is, however, worthy of serious consideration if only as a reminder that there are alternatives to the existing systems which have, by the nature of things, become 'the establishment'.

international news

CITING a sheaf of evidence which indicates that the pesticide dieldrin is highly carcinogenic to mice and rats, and that it now resides in the tissues of virtually every man, woman and child in the United States, the Environmental Protection Agency (EPA) last week abruptly halted further production and recommended that it be phased out of use as rapidly as possible.

The decision is the latest, and most significant, milestone in a four-year legal battle fought by a Washington-based environmentalist organisation to get dieldrin off the market, but it is far from the final word on the matter. Officials of the Shell Chemical Company, the sole manufacturer of the pesticide, erupted with indignation at the EPA's action, charged that "there is no evidence whatsoever to associate this chemical with cancer in man", and demanded a public hearing to state its case. The hearing is now going on, and a final decision is expected by the end of August.

If all that sounds familiar, it is. The history of the battle against dieldrin bears a strong resemblance to the long and bitter fight against DDT, although according to opponents of the pesticide the case against dieldrin is even more cut-and-dried than that against DDT. In both cases, the central issue is the ubiquity of the pesticide in the environment and the possibility that it may cause cancer in man.

Although it is a pesticide in its own right, dieldrin is also the breakdown product of the chlorinated hydrocarbon pesticide aldrin; the two agents are considered together in the EPA decision.

Firm favourites in the eyes of growers of corn and citrus fruits, the pesticides are used chiefly to control soil insects. They are applied directly to the soil in the spring, essentially as an insurance against the possibility of an outbreak of soil pests later in the year. Their longevity is thus a prime requisite, since they may have to kill insects weeks after they are put into the soil and, according to Shell and the United States Department of Agriculture which staunchly defends the use of aldrin and dieldrin, no other pesticide can remain active for long enough to do the job.

But the persistence of these pesticides is a mixed blessing, for dieldrin now contaminates many foods and is stored in high concentrations in human fatty tissues. According to a survey carried

EPA halts dieldrin production

by Colin Norman, Washington

out by the Food and Drug Administration last year, for example, measurable amounts of the pesticide were found in 83% of all dairy products, 88% of all garden fruits, 96% of all meat, fish and poultry, and in 12 to 14% of samples of grain, potatoes, fruit and some other foods. Moreover, in 1971, the EPA found that 99.5% of human tissue samples taken during autopsy or therapeutic surgery contained amounts of dieldrin averaging 0.29 parts per million.

There is thus no denying that man is constantly exposed to the pesticide. But there is considerable debate about whether this exposure carries a risk of cancer, and it is on that point that the case really hinges.

The EPA issued its order last week chiefly on the basis of studies which have shown that dieldrin "definitely causes significant increases of tumours in two and possibly three strains of mice tested", and that the pesticide has also raised tumours in two different strains of rats. The tumours, which "have been diagnosed unequivocally as malignant", appear in the liver, lungs, lymphoid tissue, thyroid, uterus and mammary glands, and have resulted from feeding tests involving doses as low as 0.1 parts per million. The EPA also cited evidence that exposure to dieldrin for periods as brief as a few weeks has caused significant carcinogenic effects in test animals.

The case against dieldrin was brought out during weeks of public hearings conducted by the EPA to determine whether or not the pesticide should be removed from the market. Those hearings are not expected to be completed until late this year or even early next year, but while they have been going on, Shell has been free to continue manufacturing both aldrin and dieldrin.

In April, however, EPA officials considered that the evidence against the pesticides—which came from studies conducted at the Food and Drug Administration, the National Cancer Institute and in Shell's own laboratories—was so compelling that they contacted

Shell officials and asked them to halt production of aldrin and dieldrin voluntarily until the public hearings have been completed. But Shell officials maintained that there is no evidence that the pesticides are harmful to man, declined to accede to the EPA's request and announced that they would begin producing next year's batches of aldrin and dieldrin on September 1. Thus the EPA moved last week to force Shell to stop manufacturing the chemicals, at least until doubts about their safety are cleared up.

For its part, Shell maintains that the animal feeding studies have little applicability to man, and that the safety of aldrin and dieldrin is assured by the fact that workers in factories manufacturing the pesticides have shown no signs of developing cancers. Lawyers for Shell have yet to present their case in full at the public hearings, and are annoyed that the EPA is trying to halt production of the chemicals before all the facts have been argued.

If Shell is allowed to go ahead with its production in September, millions of pounds of the chemicals will be distributed around the United States, and if the public hearings eventually conclude that the pesticides do pose a serious health risk, it would be virtually impossible to call all supplies in. Thus, the EPA is trying to ensure that if it bans the pesticides at the end of the public hearings, they will not continue in use for another year. □

More radiation protection

MICROWAVES and lasers are to be the first two types of non-ionising electromagnetic radiation to be taken under the wing of the British National Radiation Protection Board (NRPB) under an order extending its functions.

Since its inception as a result of the National Radiological Protection Act of 1970, the board has confined its advisory and research services to the fields of ionising radiation. Although it has no statutory powers, it advises the government and other responsible authorities on standards and safeguards against radiation hazards.

The recent order, by the Secretary of State for Health and Social Services, came into effect on August 1 and extends the functions of the board to cover potentially all electromagnetic

radiation. Its interest is being concentrated on lasers and microwaves in the first instance, say the board, not because these pose any widespread health hazard but because their use has increased enormously in the past few years and some national authoritative reference is now desirable.

Already, there is a generally agreed safety limit for continuous microwave exposure of not more than 10 mW cm⁻² average power density. This is rigorously observed by present users of radar, one of the main commercial applications of microwaves in Britain.

But there is another growing commercial use of microwaves, in quick microwave ovens which are not yet big business in Britain but whose use will probably increase. The board is setting up an advisory and research service at its Leeds centre, where ovens can be tested for radiation leakage. The second part of the NRPB's extended brief is the use of lasers. □

Taxing your sabbatical

UNTIL the end of the tax year on April 5, 1974, visitors to Britain on sabbatical leave were taxed by the British authorities on a so-called 'remittance basis'. The sum of money actually brought into the country was the base for taxation and in the six years before a sabbatical became due, many academics had learnt how to prevent most, if not all of their income of the seventh year (assuming it came from their permanent institution) from entering Britain. Legislation that has just been passed radically alters the tax position.

It is assumed in what follows that the work done in Britain is not entirely unconnected with normal duties of employment in the home country—an assumption which the tax officer is almost certain to make if the permanent institution is paying.

In the case of visitors from the United States, half of their pay will be liable to tax in Britain for any tax year in which they are in the country for 183 days or more; these days need not necessarily be consecutive. Any tax year in which visits do not add up to 183 days is not considered. A double taxation convention applies with the United States and so credit for British tax paid can be claimed against the United States tax on the same income. If a visitor becomes liable for tax through being in Britain for six months or more, he is entitled to claim full personal allowances.

Similar arrangements are in force with many other countries but tax authorities point out that it should not be assumed that arrangements are

identical and detailed information should be sought from embassies.

This change in the tax situation has been widely asserted to drive potential visitors away from Britain. In fact the most likely to suffer from it are those who have been able to find a way to avoid remitting income to this country, say by borrowing for their visit. Anyone who has had, of economic necessity, to bring his income with him, has previously had to pay tax on the full amount remitted in tax years in which he has been here for six months or more. Now he pays tax on only half that amount. □

Business: CEGB awash with capacity

by Roger Woodham

WHATEVER the Central Electricity Generating Board's financial position may be—it made a loss of £87.4 million in 1972–73—the board evidently stands no risk of running short of generating capacity as it did in the winter of 1969–70. At that time the CEGB's maximum output capacity was some 46,000 MW and the maximum demand to be met was about 38,000 MW, but for a string of reasons that were investigated by the Select Committee on Science and Technology insufficient capacity was actually available when it came to the crunch and the result was a series of voltage reductions—'brown outs'.

The situation as of March 1974 was much different in that the maximum output capacity had soared to 58,000 MW whereas the maximum demand that winter had been about 40,000 MW. The latter figure had not changed appreciably for three years (*CEGB Statistical Yearbook 1973–74*).

The inescapable conclusion is that the CEGB has an unrealistic amount of surplus capacity which it busily added to in 1973–74 at a cost of £189 million, representing 1,600 MW. And the plant now under construction which should be available by the end of 1978 will provide a further 12,000 MW, bringing the total to perhaps 67,000 MW if allowance is made for the demise of old plant. If the growth of electricity demand were about 3% a year in the next few years, the maximum call on the CEGB's services would only rise to some 45,000 MW by 1978. At that stage the board would be capable of meeting a peak demand of half as much again. Naturally some of that 'overkill' must be regarded as a provision for plant temporarily out of service, but the margin is different altogether from the 21% which proved to be insufficient—just—in exceptional circumstances in 1969–70. In 1966–67 the CEGB was getting by without bother on a margin of about 12%. □

Qualified approval for Aspartame

by Colin Norman, Washington

THE United States Food and Drug Administration (FDA) last week gave its approval for a new artificial sweetener to be used in a variety of products. Called Aspartame, it is 180 times sweeter than sugar and its official debut is significant since it comes right in the middle of an investigation of the safety of saccharin—the only other artificial sweetener on the market in the United States—which is suspected of causing bladder tumours in mice.

Aspartame loses its sweetness on prolonged cooking, however, and thus it has only been approved for such uses as sweetening tea and coffee, adding to breakfast cereals and for sweetening puddings, gelatins and artificial cream. So far, it has not been approved for use in so-called diet drinks, and it will therefore not challenge saccharin in its largest market. But FDA officials suggest privately that soft drink manufacturers will soon petition the government to allow them to use Aspartame.

So far, few people have expressed doubts about the safety of Aspartame, chiefly because it is broken down in the body into two essential amino acids, L-aspartic acid and L-phenylalanine. Furthermore, FDA's approval was based on the results of feeding studies which involved dogs and rats for two years and a number of rats which were exposed to Aspartame *in utero* and throughout their lifetimes. The studies gave no indication of tumorigenicity, and suggested that at least 2 grams per kilogram of body weight are required before any toxic effects are evident. That level is more than 100 times greater than the likely average daily intake of the sweetener in foods for for which it has so far been approved.

The FDA's decision will be closely studied in several other countries—including Britain—where applications have been made by G. D. Searle and Co., the manufacturer of Aspartame, for permission to market the sweetener. Its importance in the United States is that it gives the FDA more flexibility in dealing with two particularly sticky problems. First, the FDA has been forced to re-evaluate its decision to ban cyclamates from the market on the basis of suspected carcinogenicity (a decision is expected early next year) and, second, saccharin is now under investigation and the FDA will probably have to decide its fate within the next couple of months. Before Aspartame came along, the FDA was facing the problem of perhaps removing from the market all artificial sweeteners, but now at least it has a third product to insert into the cost-benefit equation. □

Victimisation

SIR,—What Professor Burhop in effect is saying (*Nature*, August 9) is that the "Declaration on the Rights of Scientists", made by the World Federation of Scientific Workers in 1969, is really no more than an expression of pious hopes, since there is nothing that can be done about victimisation by governments, left, right, or centre, if the governments responsible are themselves disinclined to cooperate.

As President of the W.F.S.W., Professor Burhop is no doubt well placed to judge of this. But when he goes on to say that "... the close contacts maintained between our affiliated organisations in different countries are beneficial to scientists and for science itself", one wonders whether there might not be long-term benefits for science and scientists in particular countries, if the W.F.S.W. were to make it clear that although "Our aim must be to strengthen these contacts", that policy would have to be applied selectively, where there was reason to believe that the "Declaration" was not being adhered to by the governments or affiliated organisations concerned.

Yours faithfully,

C. B. GOODHART

Cambridge, UK

Plasmid engineering

SIR,—The appeal by a committee of the National Academy of Sciences for restraint with respect to certain types of genetic experiment (*Nature*, July 19) deserves the generally favourable response accorded it (*Nature*, July 26). The potential hazards associated with the creation of artificial recombinant DNA molecules are clearly outlined in the committee's statement. However, there is an unfortunate lack of clarity in defining the types of experiment which it is recommended should be deferred. The statement concerning experiments of type I is confusing. This is particularly so if one does not persevere to the last three lines of the inordinately long sentence which excludes "plasmids containing such combinations of antibiotic resistance determinants (which) already exist in nature." The hazards associated with these latter plasmids are not potential but have already been amply demonstrated and are well understood, as explained by Dr Anderson. The NAS committee's recommendation is concerned with unnatural recombinant plasmids and it would be unfortunate if, as seems likely from parts of Dr Anderson's comment,

the lack of clarity in the definition of experiments of type I led to the inclusion in the recommended ban of experiments concerned, not with future potential hazards, but with those already with us and in need of attention.

Much work is in progress, including my own, with the specific objective of seeking means for the effective elimination of plasmids from bacteria. It would be against the spirit of the NAS committee's aims if misinterpretation of the nature of experiments of type I brought to a halt, even temporarily, experiments carrying no potential hazard from new recombinant DNA molecules, but concerned with already existing hazards in clinical practice and animal husbandry.

Yours faithfully,

G. R. BARKER

Manchester, UK

Scientists don't move

SIR,—Your editorial of July 26 on Sir Hermann Bondi's report on the interchange of scientists was very critical of the lack of mobility of scientists, and could scarcely believe that they are inhibited from changing jobs because of the difficulty of moving house. My recent experiences may help you to understand the problems.

Last December I moved from a civil service post in Farnborough to a research fellowship at Leicester University. It took the Civil Service Department over four months to determine the transfer value of my pension, but this was certainly no obstacle to me. Indeed I think that the preservation or transferability of pension rights is of little concern to the young scientist contemplating a move. My new employers seem to be unusually generous by contemporary standards in that they reimbursed a large part of my "removal expenses" and also provided a small second mortgage loan at low interest rate. Even so we have been faced with unreimbursable expenses in the present dormant housing market of more than £2,000—probably nearer £3,000 by the time the flat is sold.

My present contract lasts for only three years, and, with the present tendency of university science departments to contract, it is entirely possible that I shall have to move again in 2½ years' time, with, no doubt, a repetition of these expenses.

In North America or any other country of Western Europe, people

in our position find it quite natural to rent a house for a few years; here it is impossible to find unfurnished accommodation. Even worse, the 1974 Rent Act, by giving security of tenure to furnished tenants as well, has made us abandon any idea of letting our empty flat in this way. It seems to be the policy of both major parties that every family should either own its own home or be a council tenant, but there can be little doubt of the severe effects of this policy on the mobility of all labour, and not just scientists.

While I have no regrets at the change in my working environment which I have bought at the price, perhaps, of two years' salary, I feel unable to criticize the many scientists who do not choose to follow my example. They too may count the cost, and they may feel that boldness in pushing back frontiers is not incompatible with financial solvency.

Yours faithfully,

C. G. PAGE

Collecting egg-whites

W. R. P. BOURNE (*Nature*, 249, 793; 1974), seems determined to continue to hound Professor Charles Sibley for his comparatively minor indiscretion (with the connivance of others) in obtaining the eggs of certain birds unlawfully.

Professor Sibley is not, and never has been, an egg collector in the accepted sense as the title of Bourne's article suggests. Indeed his interest in eggs has been confined to the analysis of egg-white protein and the taxonomic value of such analysis as far as avian relationships are concerned.

Whatever the final results of Professor Sibley's researches may be, it is certain that they will be studied by all who are interested in the many unsatisfactory aspects of the classification of birds, typified, for instance, by the Babblers (Timaliidae), for too long the despair of orthodox systematists.

news and views

Current work with the voltage clamp

THE present view of the ionic basis of the action potential in nerve cells depends largely on the classic voltage-clamp experiments of Hodgkin and Huxley, published in 1952 (*J. Physiol.*, **116**, 449). Although it is remarkable how well this analysis has withstood the test of time, recent work has shown that the changes in potassium permeability are more complex than previously realised and that Ca^{2+} ions may play an important part in the inward current in many neurones.

The action potential of nerve cells is essentially a transient reversal of the voltage across the cell membrane. Hodgkin and Huxley showed that it is generated by brief, sequential increases in the membrane permeability first to Na^+ ions and then to K^+ ions. They used a voltage-clamp system to control the membrane potential of a squid giant axon, and were able to measure the currents flowing across the membrane. Following a large depolarisation the current first flowed inwards, and then rapidly reversed and was maintained in an outward direction, as shown in the figure (a). This membrane current could be separated into an inward one carried by Na^+ , and an outward one carried by K^+ . The Na permeability was rapidly switched on, or activated, and then inactivated after a short delay. The K permeability was activated only after a short delay, but was apparently not inactivated. It remained constant until the depolarisation ended.

Within a few years of this elegant work it was shown in several preparations, particularly in mollusc nerve cell bodies, that the removal of external Na does not block action potentials. Voltage-clamp studies have now demonstrated that the inward current can be carried by Ca^{2+} as well as, or instead of, Na^+ . Some Ca^{2+} may pass through the standard Na permeability system (Baker, Hodgkin and Ridgway, *J. Physiol.*, **218**, 709; 1971), but it is not yet clear whether there is a separate permeability system which handles most of the Ca current. Geduldig and Greuner (*J. Physiol.*, **211**, 217; 1970) reported that the activation properties of Na and Ca permeabilities in *Aplysia* neurones are different, suggesting separate systems. Kostyuk and colleagues (*Pflügers Arch. ges. Physiol.*, **348**, 83; 1974) and Standen (*Nature*, **250**, 340; 1974), both using snail neurones, have recently presented evidence, however, that the two ions use either the same system or, possibly, parallel ones with identical kinetics.

Even more involved than these complications of the early inward current system are those concerning the K permeability. As well as the well-established (or slow) outward K current, Neher (*J. gen. Physiol.*, **58**, 36; 1971) found a fast outward K current in snail neurones with kinetics similar to those of the inward current. Connor and Stevens (*J. Physiol.*, **213**, 31; 1971) also separated the potassium current that they measured in dorid neurones into a fast component that had both an activation and inactivation mechanism and the more usual slow component. This fast K current seems to be particularly important in controlling pacemaker activity, and may play an important part in repetitive firing.

Another aspect of the K current which has recently

come to light is the observation of a K inactivation mechanism. Whereas Hodgkin and Huxley's K current was maintained indefinitely during a depolarising step, several recent experiments have shown that it can decline (see figure b). Connor and Stevens found that the slow component of the K current inactivated with a time constant of several seconds. They also showed that it was a distinct phenomenon (that is, not a simple inactivation of the fast K current) by demonstrating differences in the voltage-dependent characteristics and the responses to TEA. Many examples of K inactivation have now been reported: to cite only two of them; Leicht, Meves and Wellhoner (*Pflügers Arch. ges. Physiol.*, **323**, 63; 1971) measured an inactivation of the delayed K current in snail neurones with time constants of 0.5–1.75 s and Ehrenstein and Gilbert (*Biophys. J.*, **6**, 553; 1966) found a similar inactivation in squid axons with a time constant of 11 s. Such slow processes, although obviously of no importance in the generation of single action potentials, could play an important part in the long-term firing characteristics of the cell.

One difficulty with the voltage-clamp technique is that it only measures the net membrane current. It is not always easy to determine whether changes in the recorded current

Hypothetical voltage-clamp records of voltage or current against time.

result from changes in an inward or an outward component. Although it is relatively easy to establish that the inward current is carried by Na^+ or Ca^{2+} ions by removing them from the external solution, it is difficult to show directly that K^+ ions carry the outward current. An elegant way of doing this was recently reported by Neher and Lux (*J. gen. Physiol.*, **61**, 385; 1973). They used a K^+ -sensitive microelectrode to measure changes in K^+ outside snail neurones, and showed that the total amount of K^+ released by the cell during a clamp pulse was in good agreement with that calculated assuming that the outward current was carried only by K^+ ions. Lux and Eckert (see page 574 of this issue of *Nature*) have now applied this ingenious technique to a study of apparent K inactivation. When the outward current was reduced by procedures expected to produce K inactivation, the actual release of K^+ , as determined by the K^+ -sensitive microelectrodes, was not equally reduced. They conclude that there must be a slow inward current as well as the normal slow outward current. Part of the apparent K inactivation was the result of this unsuspected inward current, which would make the outward current as recorded by the clamp smaller than the true outward current. The ion or ions carrying this slow inward current are so far unidentified, but are presumably Na or Ca.

ROGER C. THOMAS
L. DONALD PARTRIDGE

Germline antibody genes

THE genetic basis for antibody diversity is a subject of continuing interest though the argument between germline and somatic models of antibody diversity has abated recently. The large number of different amino acid sequences so far determined for V regions of mouse Kappa chains, point to there being at least a hundred V_{Kappa} genes and there is probably a similar minimum number of V_{H} genes. The question as to whether somatic processes are used to increase the diversity encoded in the multiple germline V genes remains open. Now the major effort is aimed at defining the way in which the V and C genes are arranged in a chromosome and the way in which they function.

At present it is thought that the genes which code for H chains (V_{H}) are present on the same chromosome with the set of about ten C_{H} genes, one C_{H} gene for each class of antibody. In this model any V_{H} gene can be paired with any C_{H} gene to give a gene pair coding for a single heavy chain. Although there is considerable evidence to support this scheme, at present it is only an outline of what must be a fascinating genetic process. The C genes for both light and heavy chains map as single genes in a Mendelian fashion. Similar mapping of individual V genes has been limited by the lack of suitable phenotypic markers. Recently individual antibodies have been characterised by either their idiotype (characteristic antigenic determinants defined by antisera raised against the antibody under study) fine specificity (definition of an antibody combining site by the quantitation of cross reactions) or spectrotpe (characteristic isoelectric focusing spectrum of an antibody). Using these genetic markers six V_{H} genes have been identified in the mouse and a search is now being made for recombinants so that a map of the V_{H} region of the chromosome can be drawn. Each of these V_{H} genes, in agreement with the model I have mentioned, has been found to be closely linked to the C_{H} loci.

Eichmann, Tung and Nisonoff reported in last week's edition of *Nature* (250, 509-511; 1974) strong evidence for a recombinational event separating two of the known V_{H} genes *ARS* and *A5A*. These genes had been identified by

the idiotype present on A/J strain mouse antibodies directed against *p*-azophenylarsonate (*ars*) and group A streptococcal carbohydrate respectively. A/J mice can make a variety of different antibodies directed against each of these two antigens. The initial response of A/J mice to *ars* always includes an antibody (or a family of antibodies) carrying the *ARS* idiotypic determinant. The *A5A* idiotype has been found to be associated with a particular antibody spectrotpe and cells producing that antibody have been cloned *in vivo* (*Eur. J. Immunol.*, **2**, 301; 1972). The inheritance of *A5A* in the C_{H} linkage group was shown by Eichmann and Berek (*Euro. J. Immunol.*, **3**, 599; 1973) who mated A/J mice against BALB/c mice, a strain which efficiently makes antibody against group A carbohydrate but has never shown that *A5A* idiotype; the F_1 progeny were backcrossed against BALB/c. Of the backcross offspring 16/29 were homozygous for the BALB/c C_{H} genes; all but one of those 16 were, as expected, negative for the *A5A* idiotype on their anti-group A carbohydrate antibody. The odd mouse BB♂7 showed a recombinant phenotype with the *A5A* gene apparently present in the BALB/c C_{H} linkage group.

In Eichmann *et al.*'s latest study, BB♂7 has been again backcrossed against BALB/c and the progeny support the idea that a new linkage of *A5A* to the BALB/c C_{H} loci has occurred as the result of a recombinational event. Many of the progeny of BB♂7 have been tested for the *ARS* idiotype. In this respect the backcrosses behave just like the parental BALB/c mice and make anti-*ars* lacking the *ARS* idiotype. The one recombinational event observed among the three genes under study is consistent with a simple linear map *A5A*—X—*ARS*— C_{H} —where X shows the position of the crossover. Further crossovers are needed in order to estimate map distances between these three genes.

The occurrence of a recombinant in only sixteen progeny in which it could be detected is either a very fortuitous event or else it is indicative of a large map distance between *A5A* and the other two genes. One map distance in the H chain linkage group of the mouse was reported by Riblet at the workshop on immunoglobulin variable region genetics (Bethesda, Maryland, March 25 and 26, 1974). Riblet studied the *DEX* gene which is characterised by an idiotypic specificity found on two BALB/c myeloma antibodies binding α -1,3 dextran. Only two recombinational events were observed in a total of 530 crosses in which a recombination could have been detected. At the time of writing their article, Eichmann and his colleagues had screened 73 meaningful crosses and BB♂7 remains the only recombinant. The next recombinant is keenly anticipated since the measurement of the distance between *A5A* and *ARS* will be indicative of the number of V genes which might lie between these markers.

ALAN R. WILLIAMSON

Reappearance of hexosaminidase A

SINCE it became possible to fuse somatic cells using Sendai virus people have been investigating the complementation (supply of the other's needs by each parental cell) of closely similar genetic defects. Complementation, in hybrids and heterokaryons (the multinucleated cells produced by fusion) has provided useful information about recessive mutants, in cases, for example, where the precise metabolic lesion is not known and genetic heterogeneity has been neatly demonstrated (see, for example, Kao *et al.*, *Science*, **164**, 312; 1969; de Weerd-Kastelein *et al.*, *Nature*

new Biol., 238, 80; 1972). If different genes are defective in each parent then the normal gene product from the opposite parent in each case will be present in the hybrid with comitant 'normal' or 'heterozygote' phenotype—namely intergenic complementation. If on the other hand the two parental cell lines have a mutation at the same gene locus, complementation does not usually occur; the hybrid line also shows the defect.

Different mutations at the same locus, however, can it seems sometimes complement each other (interallelic complementation) as the result of the formation of functional proteins (enzymes) made up of two different types of defective subunits, the variant gene products from each parent. Although interallelic and intergenic complementation are indistinguishable when the primary product of the relevant gene is not identified, in cases where an enzyme deficiency has been observed in the parental cells, the newly synthesised 'hybrid' enzyme produced as a result of interallelic complementation would probably show differences in property from the normal enzyme.

Genetic complementation has now been pleasingly demonstrated in heterokaryons made by fusing skin fibroblasts from patients with Tay-Sachs and Sandhoff's disease, two clinically very similar diseases characterised by the excessive accumulation of the ganglioside GM₂ in the brain. In the tissues of patients with Tay-Sachs disease the enzyme N-acetyl β -D hexosaminidase A is absent and in Sandhoff's disease both major forms of N-acetyl β -D hexosaminidase (A and B) are deficient. What Thomas *et al.* have done (see page 580 of this edition of *Nature*) is to demonstrate that hexosaminidase A (as well as B) is synthesised in the heterokaryons. Unfortunately, this finding does little to quell the dispute about the relationship of the hexosaminidase isozymes, because it can be explained by all the current models.

Until the past week or two only two main models had been considered in the literature. The first is that B, the precursor enzyme, determined by locus 1, is enzymatically converted secondarily (by the product of locus 2) into A; and the second and perhaps most favoured theory is that A and B possess similar and dissimilar polypeptide subunits ($A=(\alpha\beta)_n$; $B=(\beta\beta)_n$ or $(\beta\gamma)_n$) α being deficient in Tay-Sachs and β in Sandhoff's disease (see, for example, Carroll and Robinson, *Biochem. J.*, 137, 217; 1974; Srivastava and Beutler, *J. biol. Chem.*, 249, 2054; 1974). Both of these models invoke at least two separate gene loci, a different one being affected in each

disease, and if either is right the synthesis *de novo* of hexosaminidase A in heterokaryons and hybrids would be predicted. If, however, only one gene were involved, the finding could still be explained by the formation of a hybrid enzyme by interallelic complementation. Yet another lengthy article on the interrelationship of the hexosaminidases has just appeared in the *Journal of Biological Chemistry* (Tallman *et al.*, 249, 3489; 1974) and these authors conclude that the A and B enzymes are conformational isomers—a one gene model. They propose that the mutation leading to Sandhoff's disease affects the active site of the enzyme, thus both conformers are absent, and that that leading to Tay-Sachs disease causes instability of the 'A' conformation. In the light of this new claim it might then be worth studying the properties of the heterokaryon hexosaminidase A in rather more detail. It would not, however, seem surprising if the task were unrewarding because despite the wealth of arguments concerning the biochemical and immunological properties of the enzymes one simple yet important set of findings is not readily compatible with this one gene model. This also comes from somatic cell hybrid studies. In human/mouse hybrid cells (in which many of the human chromosomes are lost) the human hexosaminidase A could be lost without B, and its loss has been associated with the loss of a particular human chromosome (Lalley *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, 71, 1569; 1974).

Complementation then of these two mutant lines does not seem to have solved the hexosaminidase puzzle, but it does provide another example of virus fusion in which interesting observations can be made from heterokaryons without the use of a system to select for mononuclear hybrid cells. The success of this experiment should provoke somebody into attempting the same thing with other mutant hexosaminidase lines—which might just turn out to be more informative.

From a Correspondent

Bugs are beautiful

from our Experimental Psychology Correspondent

It might seem that using the computer as a theoretical vehicle in the exploration of the mind constitutes about as reductionist a strategy as one could devise: likening thought to processes involving punched cards and electronic circuits. But to judge from the discussions at the Artificial Intelligence Society of Britain (AISB) Summer Conference held at the University of Sussex from July 8-10, many of the

Left: intended drawing of stick man; right: attempt by program with bugs (arrows represent tracks of pen).

practitioners of artificial intelligence take up on the contrary a very mentalist stance indeed. A couple of speakers who described their work as simulating neural processes, or making computational models of the cortex, attracted energetic comment from other participants.

Although the size of the conference indicated that artificial intelligence is now well established in Britain, the stars of the show were undoubtedly the speakers from the large American centres of AI, and in particular from the Massachusetts Institute of Technology. In that region at least it is neither the potential for stimulating neurones, nor the automation efficiency of the computer that is a source of light on the nature of intelligence at present. The elucidation emanates from an examination of 'bugs'—the programming errors which prevent the actuality of programs from reflecting the aspirations of the programmers.

Typical of this kind of work at MIT is I. P. Goldstein's program which takes a specification of a simple picture, in descriptive terms, including the names of its parts (for example, head, body, legs) and relational statements such as that the legs and body are connected, the arms are below the head and so on. It also has as part of its input a program intended to draw a stick man, which represents an approximate solution, but which has bugs in it (see figure). What the debugging part of Goldstein's program knows is a good deal about the structure of simple programs in which parts (for example, procedures) can be corrected and executed independently of other parts. It also has some problem specific knowledge about how to relate descriptions in the non-procedural descriptive statement of the specification to the primitives of the graphical procedures which can draw pictures. What the whole program does in effect is to edit and rewrite parts of itself in the light of its failures to achieve its specific performance.

This provides a view of the problem solving process in which a coherent strategy, albeit containing misconcep-

tions and shortcomings, is executed. The mistakes so generated are regarded as valuable rather than unfortunate, because they can give the information necessary to improve the program's or the programmer's grasp of the process. This view is, for instance, quite different from the approach to problem solving taken in the General Problem Solver, or in most game playing programs, where absurdly large numbers of microscopic actions are searched through to see if the program can stumble across a sequence of moves that provide a solution. That approach is the domain of the combinatorial explosion: the number of moves to be searched grows astronomically as the program peers rather blindly ahead.

Programs which debug themselves, like Goldstein's, or G. J. Sussman's program called 'Hacker' whose skill improves with practice, or the construction of a programming apprentice which is being designed by C. Hewitt and his colleagues (MIT) to cooperate in the design and testing of a program, represent what looks like a productive approach to problem solving. Mistakes are valuable in that they represent interaction of a program with its environment, the experimental disconfirmations generated by a programmed theory about how to do something. An initial strategy for designing a process will almost certainly fall short in some way, but if the programmer gets about it properly, the nature of the failure can indicate a new and better theory of how that process works or can be designed.

The emphasis on bugs and debugging constitutes another new departure in AI. Bugs provide a further way in which interaction with computational forms extends the understanding of intelligence. The task is not really to simulate the brain, nor to discover that intelligence is so hopelessly complex that we continually find ourselves trying to defuse one combinatorial explosion, after another. It is more a case of providing ourselves with better ways of thinking about thinking: more penetrating and productive metaphors for the mind than Freud's bubbling cauldron of the unconscious, or the self-operating supermarket door of stimulus-response theory. New insights into thought processes may emerge from looking at the nature of bugs and the ways they are made, and from the attempt to formalise the process sufficiently to write programs that debug themselves. It can then be seen if the experience and understanding gained encourages thought not just about program bugs, but how people do learn, or could learn, from their mistakes.

Sahara spreads south

from Peter D. Moore

DURING the past century the Sahara Desert has expanded very considerably, particularly in a southerly direction. As a result the lands along the southern edge of the Sahara, which have long been used for grazing by nomadic tribes, no longer support savanna grasslands but have been engulfed by the desert.

Recent attempts at explaining this expansion have centred around the concept of climatic change; for example, Lamb (*Phil. Trans. R. Soc.*, **A276**, 195; 1974) has reviewed evidence for climatic changes during the past 5,000 years. Although he considers it impossible as yet to construct vegetational maps for early civilised times, there is evidence which suggests that the Sahara has enjoyed higher levels of rainfall. Rock drawings of animals have been found in western and central areas of the Sahara which suggest that game was once available where it no longer exists. Skeletons of elephants have even been found, so some surface water must then have been available. The level of Lake Chad (southern Sahara, 13°N) was more than 30 m above present day levels 5,000 yr ago; also, at that time, the level of the Nile floods was far greater than has regularly been experienced since. In Lamb's opinion, the equatorial rains ranged farther north during their seasonal migration which could have resulted in a regular rainy season to 20°N and erratic rains further north still. As a result one would expect a greater abundance of subsoil water than is now the case.

A consideration of rainfall patterns in the area during the past 70 yr (Winstanley, *Nature* **245**, 190; 1973) has shown that there has been a considerable decrease in rainfall in the southern Sahara since 1960 (from 165 mm to 100 mm in 1970, using 5 yr running means). In Winstanley's view this represents a southerly shift in isohyets of 9 km per year. Since there is a steep spatial gradient of rainfall in this area this could account for the spread of desert conditions.

Back in 1952 a rather different view prevailed. Richards (in, *The Tropical Rain Forest*, Cambridge, 1952) considered that the expansion of savanna grasslands at the expense of rain forest south of the Sahara was the result of an increased use of fire by man in the area. Similarly the spread of the desert has often been attributed to human mismanagement. This view has recently been reiterated by Cloudsley-Thompson (*Envir. Conserv.*, **1**, 5; 1974). He considers that the use of fire by man, which can now be traced back

more than 50,000 yr in East Africa, is a critical factor in the development of savanna and the subsequent spread of desert, but that the additional pressures imposed by overgrazing also deserve attention.

Undoubtedly overgrazing has been an important factor, especially where goats have been involved, and it can result in the production of desert-like conditions even in situations where rainfall is moderate, for example 635 mm in Karamoja, Northern Uganda. In addition to the removal of vegetation cover, the influence of trampling on soil erosion may also be considerable.

It is, however, impossible to ignore Winstanley's data or to regard them as unimportant. The response of vegetation to climatic change in the absence of human-induced factors is essentially slow, as the result of the long generation time of many climax-dominant species and to the influence which plants have on local microclimate because of their canopy structure. Thus vegetation, particularly if it is structurally complex as in the case of forest, possesses an inertia which buffers it against minor climatic fluctuations. One of the most important influences of man on world vegetation has been the simplification of the structure of habitats by felling, burning and grazing, with a resulting modification of microclimatic conditions close to the ground. Soil hydrology and nutrient content are also affected by such processes. It is likely that the high intensity of grazing imposed on the savanna south of the Sahara has rendered the vegetation of the area particularly sensitive to the changes in rainfall pattern. The result has been the spread of the Sahara.

Galactic chemistry

from Virginia Trimble

THE problems of determining the abundances of the chemical elements and accounting for them in terms of a theory of nucleosynthesis and the evolution of our Galaxy involves almost every branch of astronomy, and many related sciences, from objective prism spectroscopy and neutron activation techniques to nuclear shell models and computerised histories of the Galaxy. It is not, perhaps, surprising then that no single, clear picture of nucleosynthesis and evolution emerged from the NATO Advanced Studies Institute on the origin and abundance of the chemical elements, held at the Institute of Astronomy (Cambridge) from July 22 to August 9. If there is any unifying principle at all, it seems to be that, wherever one looks, there is evidence that more than one

process has been at work, and that, therefore, no one mechanism or theory can hope to explain all the observed chemical and isotopic abundances.

Very broadly, one must think in terms of stars more massive than the Sun undergoing nuclear reactions throughout the history of the Galaxy and returning the products of those reactions to the interstellar medium. Successive generations of stars, including the Sun and its planetary system (whose composition is, by definition, normal and the standard with respect to which enhancements or deficiencies elsewhere are measured) will then be formed from the material thus enriched in elements heavier than hydrogen and helium.

Within our Solar System, abundances can be determined for meteorites of various types, the solar photosphere, the solar corona and wind, and particles ejected by solar flares, as well as for the Earth (which is, however, so chemically fractionated as to be almost useless as an indicator of general abundance). The carbonaceous chondrites (which are the type richest in volatile materials and therefore the closest to the primitive solar nebula in composition) have, to first order, compositions and structure which can be understood in terms of temperatures at which various compounds condense from a gaseous to a solid phase, with some later remelting and fractionation of their parent body, according to E. Anders (University of Chicago). But there are additional components, amounting to 1 or 2% of the masses of the meteorites concerned which, from their isotope ratios (in one case a deficiency of ^{20}Ne and ^{21}Ne relative to ^{22}Ne , and in the other an excess of ^{16}O relative to the other isotopes), seem to represent interstellar grain material incorporated into the meteorites without ever having been vaporised and recondensed in the solar nebula, according to R.N. Clayton (University of Chicago). The Earth on the basis of its oxygen isotope ratio may also contain about 1% of this unvaporised component.

High energy particles ejected from solar flares exhibit strong variations in composition with energy below a few MeV per nucleon, but above that converge to abundances which are not significantly different from those in the solar photosphere or corona. This suggests, according to P. B. Price (University of California, Berkeley) that, at sufficiently high energies, the composition of cosmic rays coming from outside the Solar System might also reflect that of the objects which are their sources (supernovae or supernova remnants in most theories). In fact, at those energies which have been studied, the cosmic ray composi-

B and H

from Peter J. Smith

As far as units are concerned, geomagneticians have traditionally had an easy life. Geomagnetic measurements are usually made in media having relative permeability $\mu_r \sim 1$; and in the c.g.s. e.m.u. system the permeability of free space $\mu_0 = 1$. Thus the induction B is related to the field intensity H by $B = \mu_r \mu_0 H = H$ for all practical purposes. As a result of this simple equation geophysicists have seldom had to think very carefully about the physical difference between B and H ; few, if any, have really cared whether their magnetometers have measured B or H ; the gauss, the c.g.s. unit of B , has by usage become totally interchangeable with the oersted, the c.g.s. unit of H ; and as Lowes points out (*Geophys. J.*, **37**, 51; 1974), it is no longer even clear whether the gamma was introduced as 10^{-3} gauss or 10^{-3} oersted.

The recent recommendation by the International Association of Geomagnetism and Aeronomy

shows unmistakable signs of spallation (which greatly enhances the amount of Li, Be, and B among other things) as a result of passage through the interstellar medium. After corrections for spallation, the apparent cosmic ray source composition, as determined by M. Shapiro (Naval Research Laboratory) and others, still has a great enhancement of heavy elements in general over hydrogen and helium and of the iron peak elements with respect to C, N and O. There may, in addition, be an excess of U and Th and other nuclei produced in the r process (in which neutrons are captured rapidly by iron peak nuclei and the resulting unstable products then beta decay back to stability). The cause of these anomalies must be apportioned between the processes which produce the nuclei that become cosmic rays and the processes that accelerate the nuclei to relativistic energies. It is not clear how this apportionment should be made.

A recently discovered, low energy component in the cosmic rays has a quite different set of anomalies (O and N enhanced with respect to C, and enhanced He which is pure ^4He). These have been attributed on the one hand to processes in the sources, assumed to be ordinary novae, by D. Clayton (Rice University) and F. Hoyle (University of Manchester) and, on the other hand, to preferential leakage into the heliosphere of atoms with high ionisation potential, by R. Ramaty and

(IAGA) that the geophysical community adopt the SI system has given cause for a little thought, although insofar as the conversions from c.g.s. may be made by simple numerical factors, life will probably go on much as before. Indeed the basic decision about whether to express results in terms of B or H (necessitated by the fact that in SI, $\mu_0 = 1$) was made by IAGA in favour of B in the "interest of achieving... the least possible disruption of existing numerical usage" and in spite of protestations that "matters of physical fact are involved" (Whitworth and Stopes-Roe, *Nature*, **234**, 31; 1971).

In any event, Lowes has now shown that, whatever it may say on the label, real magnetometers have calibrations which depend on the permeability of the medium in which the field is measured. Magnetometers thus actually measure neither B nor H exactly; and so from the instrumental point of view there is no reason for preferentially choosing either for expressing magnetic field data. Not that this will prevent controversy in the future, of course!

others at Goddard Space Flight Center, where the new component was discovered.

The most striking recent progress in measuring abundances has been made by a group at Princeton University as a result of Copernicus observations of ultraviolet interstellar absorption lines. They have obtained a relatively coherent picture, in which the elements that are most depleted from the general interstellar gas onto grains are those that condense at the lowest temperatures. This is reminiscent of the situation in meteorites.

Among the stars, the extraordinary enrichment of the surfaces of certain peculiar A stars in Eu and other rare earths seems, from the work of G. Michaud (University of Montreal), to be attributable to diffusion in the outer layers of stars with initially normal composition. A new class of CH subgiants, discovered by H. Bond (Louisiana State University) has, on the other hand, overabundances of C, Nd, Ce and La, combined with a deficiency of other metals, which seem to reflect mixing to the surface of material which has undergone nuclear reactions in the interior of the stars.

The theoretical models of element production tend to reflect the multiplicity of components in the observations. Several theorists, including I. Iben (University of Illinois) and S. Woosley (California Institute of Technology) have followed the assorted processes (hydrogen and helium burning; hydro-

static and explosive carbon and oxygen burning; explosive silicon burning; and the rapid, slow, and equilibrium capture of neutrons) which should occur in the various layers of normal stars. By a judicious mixing of the products of the various processes (corresponding roughly to the masses in each of the layers), they have succeeded in reproducing the observed abundances in the Solar System over a wide range of atomic numbers while using a rather small number of adjustable parameters.

On a still larger scale, W. D. Arnett (University of Illinois) and R. Talbot (Rice University) and B. Tinsley (University of Texas, Dallas) have formulated models of the evolution of our Galaxy as a whole which can reproduce the variations of total metal abundance with time and position in the galaxy as well as the percentages of matter now present in the form of gas and of stars of various masses and compositions. The models are by no means unique.

Lizards and dune buggies

from our Animal Ecology Correspondent

NOBODY can doubt that increased leisure time available to people living in affluent societies is on the verge of creating immense environmental hazards. As it seems likely that time and money are going to be increasingly plentiful in the future, it is high time that ecologists and politicians got together to formulate useful legislation. This must be tailored to suit the specific ecosystems under pressure and no area, however barren, should be thought to be unworthy of inclusion.

The vast Mojave desert of the southwestern United States is one such barren area that has been used for more than a century for mining and domestic stock grazing. Today it is an important playground for the people of California and, as might be expected, the huge pressure so induced is taking its toll. At a conservative estimate there are 1.2 million motor cycles and 500,000 dune buggies in California most of which are used for scrambling and other off-road pursuits. A most useful pilot study of the impact of both vehicles and sheep on the Mojave has been made by Busack and Bury, and it is to be hoped it does not escape the attention of environmental decision makers (*Biol. Conserv.*, **6**, 179-183; 1974).

Dove Springs canyon, 23 km N and 9.5 km W of California City, was chosen as a study site since it is a popular place for buggy racers to display their talents. Three 1 ha plots representing heavy use, moderate use and no use were established and all the

resident lizards in each were collected during a 3-day period. The conditions under which the census was made satisfy the restrictions as to effectiveness laid down by Zippin (*Biometrics*, **12**, 163-189; 1956). Some lizards were caught by hand (the rare ones which were subsequently released), some were shot with 0.22 dust shot and others were shot with elastic bands. In the heavily used area, where the vegetation was severely reduced, only two lizards (*Uta stansburiana*) were caught. In the moderately used area 15 lizards were taken adding *Callisaurus draconoides* and *Cnemidophorus tigris* to the list. The biomass of lizards in this area was more than 48 times greater than that in the first area. The unused plot yielded 24 lizards (the three species mentioned plus *Crotaphytus wislizenii*) and had a biomass almost double that of the moderately used area. If lizards can be taken as indicator species of general ecological complexity—and being insectivorous this seems not unreasonable—there seems to be a case for speedy legislation to restrict dune buggy racing only to certain areas.

Grazing has different effects on lizards. Previous studies of desert vegetation have indicated that grazing does not greatly affect the diversity of plant species (Blydenstein, Hungerford, Day and Humphrey, *Ecology*, **38**, 522-526; 1957; Gardner, *Ecology*, **31**, 44-50; 1950). Protection from grazing serves to increase biomass without seriously affecting ecological complexity. In Gardner's study 30 years' protection from grazing brought about a 110% increase in biomass. The ungrazed study plot used by Busack and Bury yielded 36 lizards with a total biomass of 690 g ha⁻¹; of this 6 *C. draconoides* comprised less than 10% of the total biomass. The plot which had been heavily grazed by sheep in the previous year revealed 17 lizards with a biomass of 185 g ha⁻¹. Interestingly, of this 17, 11 were *C. draconoides* which comprised almost 70% of the total biomass. *Phrynosoma platyrhinos* and *C. wislizenii* were absent from the grazed plot. The likely interpretation of these observations is that the vegetational changes associated with grazing reduces to below an acceptable exploitable level the population of insects required by these species. *C. draconoides* is an agile lizard that favours open areas with scant plant growth and small rocks. The effect of grazing is to produce these conditions.

Both motor cycling and buggy racing have an important influence on community structure which could result in irreparable ecological damage. Strict control over who does what where in the Mojave will be required if the whole place is not to become unfit for lizards and thus, in the long term if not in the short, unfit for any kind of human use.

Lattice defects in Freiberg

from John Walker

THE latest in the series of international conferences on lattice defects in semiconductors, held at Freiberg from July 22-25, was opened by G. D. Watkins (General Electric, Schenectady) with his traditional review of spin resonance studies in silicon. The self-interstitial has still not been isolated, but seems to be produced in a positive-charge state during irradiation. It is then trapped by and changes place with the negatively-charged acceptors in p-type material. This trapping does not occur in n-type material, so the damage rate is lower, though boron counterdoping increases it. The importance of oxygen in radiation damage was emphasised by the identification of the Si-G3 and Si-G4 centres as vacancies perturbed by oxygen atoms. Both defects anneal to give the well-known A-centre (an oxygen-vacancy pair).

R. P. Messmer (General Electric, Schenectady), in his review of the theory of point defects in semiconductors, described the X α scattered wave theory which has been used to illuminate the controversy between many-electron and one-electron treatments of the diamond vacancy. Apparently the electrons are not sharply localised at the defect, but spill out into the surrounding lattice. Hence electron-electron interaction is reduced and the one-electron calculations are adequate. This is consistent with experimental results on silicon, but the data are not available for diamond.

In the diamond session, L. A. Vermeulin and colleagues (Universities of Reading and the Witwatersrand) reported the observation of sharp photoconductivity peaks in irradiated diamond crystals, which suggests the existence of bound states within the conduction or valence bands. J. W. Van der Sande (University of the Witwatersrand) has used the low temperature thermal conductivity of irradiated diamond to demonstrate the presence of interstitial clusters 200 Å in diameter; these indicate that defects are mobile below room temperature.

Phosphorus ions, when ion-implanted into silicon in a random direction, penetrate further than expected. Explanations which have been suggested are diffusion and the scattering of ions into channelling directions. P. Blood and colleagues (Mullard Research Laboratories, Redhill and AERE Harwell), in a very elegant experiment, prepared a thin silicon crystal and implanted radioactive phosphorus ions into it. Diffusing ions would necessarily remain in the crystal,

whereas channelled ones could emerge from the back face and be trapped in a second, adjacent crystal. Radioactive ions were found in the second crystal, so channelling was indeed occurring.

D. V. Lang and L. C. Kimerling (Bell Laboratories) introduced a powerful new tool for the study of defect states within the forbidden gap. Deep level transient spectroscopy can detect the activation energy for thermal emission from a defect level to the band edge, the defect concentrations, their spatial profile and the electron and hole capture cross sections. All these parameters are of obvious interest to device manufacturers as well as academic physicists. A voltage pulse fills with charge carriers the defects within the depletion region of a p-n junction. The trapped carriers are then released and cause a capacitance transient whose magnitude and time constant, combined with the device temperature and the width of the depletion region, indicate the above parameters. The technique is also relatively cheap and simple to operate.

Genetical hazards of pollutants

from A. D. Bradshaw

HUMAN beings are rather ambivalent to problems of pollution. On the one hand people can get very worried by them, and yet on the other hand they all too easily dismiss them. It was for this reason that the Genetical Society held a symposium on the subject on July 10-12 during their summer meeting at Lancaster. Eight invited speakers provided an assessment of the current state of knowledge about the genetical effects of pollution.

These effects fall into two distinctive parts—selection and mutation. It was clear that a great deal is now known about the selective effects of pollutants. Indeed, they provide some of the most elegant examples of evolution in action as was shown in the accounts of industrial melanism in moths by L. M. Cook (University of Manchester) and J. A. Bishop (University of Liverpool) and of heavy metal tolerance in plants by A. D. Bradshaw (University of Liverpool). These two examples are remarkably similar in the way they demonstrate the powerful effects of selection in the formation of highly localised adapted populations, particularly in organisms with limited powers of dispersal. In both cases the observed clinal patterns can be correlated with observed values for gene flow and selection.

Although the rapidity of the evolution of insecticide resistance is now well known it is doubtful if many

people realise the remarkable rate of appearance over just a few years of resistance to first one new insecticide and then another. This problem was outlined by R. J. Wood (University of Manchester) who showed how much the evolution of insecticide resistance is ruining insect control. The evolution, however, is determined by the availability of appropriate variation as well as by selection, for only some, and not all, species have evolved resistance.

It is easy to appreciate that evolution of resistance to insecticides or heavy metals, being so much a matter of survival or extinction, will be very rapid: one or two years seem to be sufficient for substantial evolutionary change. It was therefore interesting to hear from R. W. Snaydon (University of Reading) that even the quiet fields of Rothamsted Experimental Station can provide examples of equally far reaching and rapid evolution in the grass *Anthoxanthum odoratum*, in response to the different liming and fertiliser treatments of the Park Grass Experiment. Here indeed is an example which shows the very pervasive effects of evolution on all characters of an organism, and the fact that an ordinary meadow can readily generate coefficients of selection as high as 0.5 or more.

By contrast, contributions on the mutational aspects of pollution did not paint quite such a clear picture, not because of lack of importance of the subject or of lack of work, but because of the inherent difficulties of mutation research. C. E. Purdom (Fisheries Laboratory, Lowestoft) described the history of research on the effects of ionising radiation, from the early days when only the linear relationship between mutation and dose was known to the present day when it is realised that the relation is not so simple and that different species including man can show very different patterns of sensitivity.

This theme was taken up by M. F. Lyon (MRC Radiobiology Unit, Harwell) for the particular case of the effects of radiation on mammals. It now seems that repeated small doses give a lower mutation rate than the same total dose given in a single exposure. Since environmental radiation is received almost entirely in small doses or at low rates it may therefore be less hazardous than was previously thought. At the same time the yield of mutation in mice, and guinea-pigs and hamsters, suggests that mutation yield decreases with time after irradiation. All this is comforting to human beings, but there is still, for obvious reasons, no direct evidence.

The last but not least effect of environmental mutagens, particularly chemicals, is to cause chromosome change. There is enormous pressure to

produce effective means for testing the effects of new chemicals on human tissue. M. L. O'Riordan and H. J. Evans (Western General Hospital, Edinburgh) showed the value of peripheral blood lymphocytes for this purpose. But the problem is to know how far it is possible to extrapolate from such data to effects on germ cells. Certainly germ cells and embryos in human beings have their own particular properties. E. Alberman (Guys Hospital, London) very effectively brought the symposium to a close with an analysis of the causes of spontaneous abortion in human beings. It is very clear from the relation between foetal death and the presence of chromosomal abnormalities in the foetus, and between mean ovarian X-ray dose and foetal death, that abortion is a process by which human beings get rid of much newly acquired genetic abnormality.

Pacific motions

from Peter J. Smith

DEEP sea sediment cores—unlike rocks from continents, oceanic islands and seamounts—have not generally been used to reconstruct lithospheric plate motions. There are several reasons for this: azimuthal orientations of sediment cores have not usually been available, thereby making it impossible to obtain the complete palaeomagnetic information; cores have often been short, thereby limiting data in time; and there are the usual problems of dating and determining sedimentation rates, especially beyond the well defined continental polarity-time scale. Perhaps even more importantly, the sediments easier to recover are obviously the younger ones within whose span plate motions have been small. Ocean cores have therefore been most useful in polarity studies, in elucidating time-stratigraphic relationships and in determining geomagnetic field properties, although some years ago Sclater and Cox (*Nature*, **226**, 934; 1970) did show that cores can be used to trace palaeolatitude variations given adequate time coverage.

Another attempt to determine plate motions from sediments has now been made by Hammond *et al.* (*Earth planet. Sci. Lett.*, **22**, 22; 1974) using 7 cores from the central equatorial Pacific. Taken together the cores spanned completely the period 0.1–21 million years (Myr) ago, a range determined partly from magnetic and partly from biological data. For the younger sediments, dating was based primarily on comparison with the continental polarity-time scale. Sediments in the range 5–10 Myr were dated by compar-

ing the relative lengths of polarity epochs in the cores with those of dated ocean floor anomalies. For the period beyond 10 Myr ago, dates were based largely on the correlation of observed radiolarian zones with the tropical radiolarian zoning previously established.

Such dating is easier to describe than to carry out; but within the limitations of the various methods, Hammond and his colleagues go on to plot palaeolatitude (from the measured palaeomagnetic inclinations) as a function of age throughout each core on the assumption that during the relevant period the geomagnetic field has been axially dipolar. In each case, the variation of palaeolatitude with time indicates northward motion. The overall average rate of movement, based on linear least-squares regression analyses of the latitude-age data, is 8.4 cm yr^{-1} during the past 21 Myr. The average, however, conceals a significant mid-period change in motion, for about 12 Myr ago the rate of northward movement seems to have slowed from about 11 to 6 cm yr^{-1} . This could represent a genuine decrease in the absolute rate of motion, a change in direction (which could reduce the northward component of motion without necessarily reducing the actual rate), or both.

Numbers apart, the important general point demonstrated by Hammond *et al.* is that the method of reconstructing plate motions using deep sea cores can be made to work as long as the cores cover a sufficiently long interval of time. They also note that in view of the limited number of cores studied and the difficulties in dating them accurately, their own particular results must be regarded as tentative. Nevertheless, they draw attention to the fact that their overall drift rate of 8.4 cm yr^{-1} is in excellent agreement with the rate of about 8 cm yr^{-1} obtained by Grommé and Vine (*Earth planet. Sci. Lett.*, **17**, 159; 1972) from a palaeomagnetic study of Miocene basalts from Midway Atoll.

On the other hand, Hammond and his coworkers do not mention that Winterer (*Bull. Am. Ass. Petrol. Geol.*, **56**, 63; 1972) concluded (on the basis of eastern Pacific data) that the Pacific plate has been moving northwards at a rate of only 3 cm yr^{-1} for the past 30 Myr, nor that Heezen *et al.* used western Pacific data to obtain an even lower rate of 2 cm yr^{-1} . But Forristall (*Geophys. Res. Lett.*, **1**, 131; 1974) does mention this previous work, and uses it to expand some ideas of his own concerning Pacific motions.

Forristall's ultimate conclusion is that the asthenosphere beneath the central Pacific is about twice as thick as the lithosphere—a result which will cause little surprise insofar as it is in

general agreement with majority views favouring shallow convection. But the assumptions and data upon which the conclusion is based are much more contentious. For example, many will surely quarrel not only with Forristall's view that the concept of hot spots fixed with respect to each other has been conclusively rejected but also with his more fundamental assertion that "it is hard to escape the idea that linear chains of volcanic features . . . are the expression of isolated subsurface hot spots".

Be that as it may, the more important point in the present context is that in his calculations Forristall uses the northward drift rates proposed by Winterer and Heezen *et al.*, apparently rejecting the higher rate obtained by Grommé and Vine. It thus becomes clear that not only are different workers obtaining quite different figures for recent Pacific plate motion, the variety of values available provides a basis for wider conclusions. The reasons for the discrepancies in drift rate are not difficult to imagine; but until they are sorted out the confusion is likely to increase.

Observing the millenium

by John Gribbin

ON the face of things, the achievement of 1,000 issues of a journal may seem unremarkable by *Nature's* standards—this journal is now well into our sixth 'millenium' of continuous publication. But when the journal in question only appears bimonthly at best, and has recently suffered more than most from the rigours of the British three-day week, there is perhaps some excuse for dropping the mask of scientific sobriety for one celebratory issue.

The journal to which I refer is *The Observatory*, which is the house journal of the Royal Astronomical Society. The sense of humour needed to run such a journal for a body of scientists as free-ranging in their ideas as astronomers is often apparent in ordinary issues of the journal, where sober scientific papers rub cheek by jowl with letters which are sometimes decidedly peculiar (but must presumably be published if they come from Fellows of the RAS?) and with verbatim reports of meetings which are so deadpan that they have on occasion been known to reduce an astronomical coffee break to something approaching hysteria.

To anybody who has been present at the meeting being reported in any particular issue of *The Observatory*, the favoured game is to spot who has taken the opportunity (offered in the

best traditions of scientific accuracy) to change what they actually said at the meeting to what they would have said if they had either remembered, or had time, or read the papers they should have read in advance. Together with the frequent interjections from "A Fellow" (anybody present who was not recognised by the RAS scribes), this makes the meeting reports just about beyond improvement—so it is a pity that the editors of the journal thought it necessary to start their celebratory 1,000th issue with a spoof meeting report.

The spoof scientific papers are more successful, although most of them hinge upon 'in' jokes which will mean little to non-astronomers (but then, who else will be reading them?). But a couple of contributions deserve at least passing notice from the wider world of science. These are concerned with two newly discovered manifestations of the 11-year cycle which seems to be linked to many terrestrial phenomena, and may be triggered by solar activity. Research into this subject is still seen as a contentious issue in some quarters, and one of the contributors hides behind the pseudonym "Disgusted, Tunbridge Wells" (presumably A. Fellow?). What Disgusted has discovered, among other things, is that an analysis of the number of pages in each issue of *The Observatory* shows "a suggestion of the eleven-year cycle which occurs in most astronomical data". But the second communication is even more remarkable.

According to Mathews (*Observatory*, **94**, no. 1,000, 13P; 1974) there is a correlation between sunspot activity and the political "colour" of British governments. Labour governments, it seems, tend to be returned at times of sunspot minimum, and Conservative governments at times of sunspot maximum. Best of all, in a prediction made before the most recent British election but only now appearing in print, Mathews said "regions of political instability may well be triggered in the next few months, resulting in the election of a Labour Government", and also predicted "the continuation of the Liberal revival". Those predictions, of course, may well be considered still relevant today, and if Mr Harold Wilson is a reader of *The Observatory*, there might well be another election in Britain in the very near future.

This area of sunspot research is clearly an important field of astronomy today (see *Nature* **246**, 453; 1973). If there are still doubters who are unconvinced of the reality of the solar-terrestrial links let them ponder on a quote from *The Observatory* of 1877 (**1**, 370): "M. Tempel supposes that the spiral shapes (of Nebulae) are only creatures of fantasy".

Primate social organisation and ecology

T. H. Clutton-Brock

Ethology and Neurophysiology Group, University of Sussex, UK

Attempts to relate interspecific differences in social organisation among primates to gross differences in habitat or diet type have been largely unsuccessful. This is probably partly because distantly related species have adapted to similar ecological situations in different ways and partly because much finer ecological differences are important.

THE accumulation of primate field studies in the course of the last two decades has emphasised the extent to which social organisation varies between species. Marked inter-population differences have been observed in a number of cases¹, but most species possess characteristic modal patterns of social organisation. Members of some species are solitary² for much of their time, while others live in family groups^{3,4} and others in semi-stable groups of fifty or more animals^{5,6}. Groups may include approximately equal numbers of males and females⁷ or, as is more usual, there may be a preponderance of females^{8,9}. In a number of species, groups regularly split up into parties which forage separately^{10,11} while in other all members of the group stay together^{6,8}. The average size of the area used by groups differs from <0.01 to >50 km² (ref. 12).

At present, little is known about the adaptive significance of these differences. Several reviews have attempted to relate them to gross differences in diet or habitat type¹²⁻¹⁸. The first and perhaps the most influential of these was produced by Crook and Gartlan¹³ in 1966. Primate species were divided into five "grades" according to the nature of their diets, the kind of habitat they occupied and the pattern of social organisation which they displayed. The paper emphasises the similarity of social organisation in species sharing the same diet and habitat type and is widely quoted as evidence that social organisation and ecology are closely related. But when it is viewed in the light of current knowledge, differences between groupings are less impressive than differences within them. For example, *Saimiri sciureus*, *Colobus* spp., and *Gorilla* are all placed in the same grade, despite the gross differences in diet, foraging behaviour and social organisation which exist between them¹⁹⁻²⁶. In addition, the paper illustrates a fundamental problem in classifying primate social systems. Since different aspects of social organisation are not well correlated across species, categories defined by a single criterion will include social systems which differ widely in other ways.

Jolly¹² avoids this problem by considering different aspects of social organisation separately. She groups species into six ecological divisions ("nocturnal", "arboreal leaf-eaters", "arboreal omnivores", "semi-terrestrial leaf-eaters", "semi-terrestrial omnivores" and "arid country species"), and compares troop size, range and territory size, population density, inter-group behaviour and day-range size separately between ecological groups. Again, differences within most groupings are more striking than differences between them. For example, between species allocated the "arboreal leaf-eaters" category, average troop size differs from <10 to >50 and average range size from <0.02 to >1 km², while other categories show even more variability.

To criticise these reviews in the light of current knowledge is not to discount their value. The paper by Crook and

Gartlan in particular has stimulated much interest and a considerable body of research. There are, however, theoretical reasons why social organisation should not be expected to be closely correlated with gross ecological variation.

Phylogeny, ecology and adaptation

One probable reason for the absence of close correlation is that different species tend to react to similar environmental pressures in different ways. When a novel adaptation evolves, its form will be partly determined by the various environmental factors through which selection is operating and partly by the species' phylogenetic inheritance^{27,28}. Consequently, distantly related species are likely to evolve different traits with similar functions. For example, anatomical specialisations permitting the digestion of foliage have evolved in several primate families. In some this has been achieved by the development of a large caecum (for example, *Alouatta*, *Indri*)²⁹, in others by chambered stomachs with bacterial symbionts (for example, *Colobus*, *Presbytis*)³⁰. Similarly, many interspecific differences in social organisation may well prove to represent different methods of overcoming the same ecological problems.

Another reason is that the wrong kind of ecological variation has been assumed to be important. Within habitat categories as broad as "forest", "woodland" and "savanna", and dietetic categories such as "insectivore", "frugivore", "folivore" and "omnivore" there is room for vast ecological differences. Food supplies may be static or mobile, sparse or dense, heavily clumped or evenly dispersed, reasonably

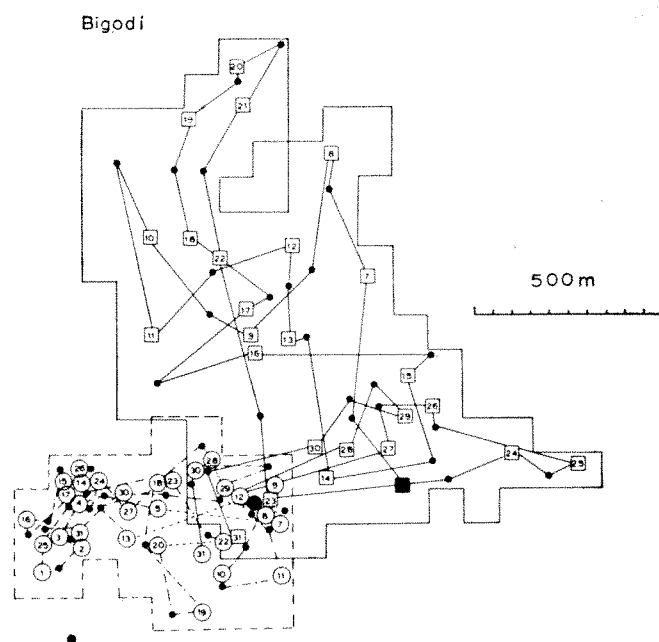

Fig. 1 Movements of a troop of red colobus (squares: September 6 to 31, 1970) and one of black and white colobus (circles: August 29 to September 31, 1970) about their ranges in Kibale Forest Reserve, Uganda. Squares and circles show the troops' night-resting positions, the figures inside them the dates. Points show the positions of the troops at 12 noon on each day.

Fig. 2 A male black and white colobus watches an intruder.

stable throughout the year or extremely variable¹⁷. Intensity of predation may vary in the same ways. If ecological differences at this level affect social organisation (and, by analogy, the plentiful literature on birds suggests that this will be found to be the case³¹) one should expect social organisation to vary widely within habitat and diet types.

A recent study of two species of colobus monkeys in East Africa³² provides an example of the level at which differences in social organisation may be related to ecology. Both the red colobus (*Colobus badius*) and the black and white colobus (*C. guereza*) are widely distributed across tropical Africa³³. The two species are sympatric throughout much of their range, though the black and white colobus is found both in wet and dry forest while the red colobus is less commonly found in dry forest^{25,34}. Although both species are largely folivorous, arboreal and forest-dwelling,³⁵ their characteristic patterns of social organisation differ widely. Red colobus live in large, multi-male troops of 40 or more animals which occupy extensive ranges of around 1 km² in size (see Fig. 1). Their different calls intergrade³⁶. Oestrous females show pronounced swelling of the perineal region. Infants have a black natal coat and are apparently handled only by the mother during the first months of life. In contrast, black and white colobus live in small troops of five to 10 animals which often contain only one adult male²⁴⁻²⁶. The troops occupy defended territories usually <0.2 km² in size and inter-troop relationships are normally hostile²⁴. Males give a booming roar which may serve to space groups³⁷ while intragroup vocalisations intergrade as in the red colobus. Females show no obvious oestrous swellings. Infants have a white natal coat and are handled by females other than their mothers from the day of birth³⁸.

Between August, 1969, and June, 1970, I observed one troop of red colobus in the Gombe National Park for 9

months³². Afterwards, for approximately a month each, I watched one troop of red colobus and one of black and white colobus in each of two areas in Kibale Forest, Uganda. I measured the amount of time which the animals spent feeding on different foods by recording, at quarter-hourly intervals, the foods that all visible animals were eating³⁹. In each area, I also measured the relative abundance of the different tree species.

The feeding behaviour of all three troops of red colobus was very similar. The animals ate the flowers, fruit, shoots and leaves of a variety of tree species. They were extremely selective in their choice of food, regularly choosing certain parts of particular tree species. Most tree species were not evenly distributed through the forest, with the result that the animals fed on different foods in different parts of their ranges. In addition, the availability of food on most species varied seasonally and this was reflected in seasonal changes in the animals' diet. When shoots, flowers and fruit were less abundant, the animals fed to a greater extent on mature leaves, though in no month did they spend more than 60% of their feeding time eating mature leaves. In all months of the year at Gombe, and in both study areas at Kibale, the animals fed on a wide variety of food species. To measure the variability of their diet, in each month I ranked the animals' foods on the amount of time spent feeding on them. At Gombe the proportion of time spent feeding on the top-ranking food species varied from 13-42% between months, that on the second ranking species from 11-21%, while the amount of time spent feeding on the top five varied from 51-80%. Figures for the two Uganda troops were similar. In one study area the red colobus spent 11% of their time feeding on the top-ranking food species, 10% on the second and 46% on the top five. In the other they spent 16% of their time on the top species, 14% on the second and 50% on the top five.

The diet of the black and white colobus troops differed in two important ways from that of the red colobus. Both troops fed almost exclusively on two tree species (*Celtis durandii* Engl. and *Markhamia platycalyx* (Bak.) Sprague). In one area *Celtis durandii* accounted for 71% of all feeding records and *Markhamia platycalyx* for 19%. In the other, *Celtis durandii* accounted for 88% and *Markhamia*

Fig. 3 A female red colobus leaps from one tree to another, her infant clinging to her chest.

platycalyx for 5%. These species were utilised to a lesser extent by the red colobus troops in both areas and the difference in feeding behaviour was not a product of reduction in the availability of alternative foods to the black and white colobus³⁹. Second, during the first weeks of the Uganda study, when few *Celtis* trees had yet come into flower or shoot, the black and white colobus fed largely on the mature leaves of *Celtis*. At the same time, the red colobus were feeding on the shoots, flowers and fruit of a variety of other food species, but were not observed to feed on mature *Celtis* leaves. Subsequently, many of the *Celtis* trees came into flower and shoot, and the black and white colobus switched to feeding on these parts.

These differences in feeding behaviour may be closely related to the differences in distribution and social organisation between the two colobus species. Black and white colobus may be able to exist on a diet of mature leaves when only these are available. This would allow the species to colonise areas of dry forest where strongly seasonal rainfall produces a high degree of production synchrony across different tree species (so that shoots, flowers and fruit are only available at certain times of year). Second, it would allow them to exist on the products of a small number of tree species throughout the year, since these would provide acceptable food in all seasons. Consequently, a small area of forest would be able to support animals throughout the year. In this situation, small troop size might permit the animals to minimise range size and thus to increase their ability to defend their food supply efficiently^{17,40}. It might also allow them to minimise the distance which they would have to travel each day to collect food (both because the total demands of the troop would be less and because they would be able to utilise food sources too small for larger troops).

In contrast, red colobus may need to maintain a high proportion of shoots, flowers and fruit in their diet throughout the year. Consequently, the species may be limited to wetter forests where some tree species carry these parts in all seasons. Since different tree species will carry acceptable foods at different times, the animals would need to maintain access to a wide variety of food species. As the distributions of most tree species are heavily clumped, a large sized range would be necessary in order to provide sufficient supplies of acceptable food in all months of the year. A square kilometre of forest can support a considerable population of red colobus. Theoretically, the animals could either aggregate into a single group or split up into several small groups with extensively overlapping ranges. In the red colobus, minimisation of group size may be less advantageous because the range size necessary to support even a small group throughout the year would be too large to be efficiently defended. Aggregation may have a number of advantages: the presence of other feeding animals in the immediate area may show individuals where to find food⁴¹, while the troop may provide a reservoir of knowledge about the distribution of food and of predators in the past⁴². It also may allow the animals to develop a pattern of regular use of the different parts of the range which would maintain leaf growth at an acceptable stage and maximise the reaction of the tree species to being cropped⁴³. Finally, large troop size may enhance the animals' ability to detect and defend themselves against predators. Certainly chimpanzees at Gombe were regular predators of red colobus (R. Wrangham, personal communication) and several instances of cooperative defence by the colobus were observed.

The origins of several other differences between the two species are probably linked with these differences in social organisation. The contrasting pelage of the black and white colobus and the males' roars may help to demarcate troops' territories (J. F. Oates, quoted in ref. 44). Differences between the two species' reactions to intruders are well

Fig. 4 Female red colobus feeding on flowers of *Commersonia bartramia*.

adapted to the difference in group size. When disturbed, black and white colobus tend to move to thick cover and remain silent while red colobus escape noisily and males may attack potential predators, including chimpanzees. Other differences, such as the absence of obvious sexual swellings in the black and white colobus and of infant-swapping in the red are less easily explained.

This reconstruction is clearly speculative. Few colobus troops were observed and, except at Gombe, they were watched only at one time of year. Current studies of the two species by T. T. Struhsaker and J. F. Oates may throw further light on the problem. But large group and range size is associated with clumped, unstable food supplies in several other animal groups. Studies of *Presbytis entellus* and *P. senex* in Ceylon show that *P. entellus*, which lives in larger troops in larger ranges than *P. senex* also feeds more on fruit and less on mature foliage and utilises a wider range of foods. Among East African ungulates, most of the plains-dwelling, grazing species, whose food supplies tend to be clumped and relatively unpredictable, aggregate in large herds which range widely (for example, most of the *Alcelaphinae*). In contrast, most browsing species, whose food supplies tend to be more uniformly scattered and more stable, occupy small ranges and live either in small groups, in pairs or alone (for example, dik-diks, duikers and most of the *Neotraginae*)⁴⁶. With some exceptions, the same association between diet and social organisation is found among European and Asiatic deer. Finally, a high proportion of graminivorous bird species feed in flocks, whereas relatively few insectivorous species do so³¹. The diet of the former is commonly assumed to be more heavily clumped than that of the latter⁴⁷. Within the insectivores, the aerial feeders (for example, swallows, martins and swifts) whose food supplies tend to be more clumped and less predictable, almost all feed in flocks³¹.

The colobus study provides one example of the kind of ecological differences which may be associated with interspecific differences in social organisation. In other primate species, different factors are likely to be important. But if many of them are as subtle as those probably involved in

this case, considerable variation is to be expected within gross diet and habitat categories. This is not to say that high level ecological variation has no effect on social organisation. Indeed, the examples quoted above suggest that in some animal groups there is a relatively close correlation between some aspects of social organisation and certain types of diet. Whether associations at this level can be identified will depend both on the number of species which in ecological categories and on the number of species which can be compared. Lack³¹, working with a vast array of bird species, was able to demonstrate correlations between social organisation and gross dietetic variation despite the presence of considerable variation within ecological categories. In primates, however, this approach is less likely to be useful both because there are relatively few species and because there is evidently wide variation within gross ecological groupings.

I thank the following for help, advice and criticism: Professor R. J. Andrew, J. Brooke, Dr J. S. Gartlan, Professor R. A. Hinde, Dr A. Jolly, M. Kavanagh, Dr H. Kruuk, Dr J. van Lawick-Goodall, Dr M. J. Simpson, Dr P. J. B. Slater, C. Packer and R. Wrangham. The field work was carried out while I was a member of the Sub-department of Animal Behaviour at Cambridge and was financed by a Royal Society Leverhulme Scholarship and a Science Research Council Studentship. I am grateful to the Tanzanian National Parks and to the Uganda Forestry Department for permission to work in the Gombe National Park and in the Kibale Forest Reserve.

Tectonic segmentation of the Andes: implications for magmatism and metallogeny

Richard H. Sillitoe

Department of Mining Geology, Royal School of Mines, Imperial College of Science and Technology, London SW7 2BP, UK

The Andean orogen consists of a series of tectonic segments separated by transverse boundaries that reflect discontinuities on the underlying subduction zone. The characteristics of belts of magmatic rocks and the type, age and size of ore deposits in a series of longitudinal belts may change at tectonic boundaries.

THE central Andes provide a classic example of a volcano-plutonic orogen developed along a convergent plate margin¹. The longitudinal continuity and transverse variability of characteristic volcano-plutonic orogens are commonly emphasised². Although I accept that longitudinal continuity is dominant in such orogens, I stress here the potential significance of a fundamental, longitudinal segmentation of the central Andes and, by analogy, of other comparable orogenic belts above subduction zones.

In Chile a series of longitudinal, physiographic provinces (the Norte Grande, Norte Chico, Central Chile, and Southern Chile) has been recognised for many years. Some of the boundaries between the physiographic provinces must have a seismic significance because they coincide with positions at which the level of seismicity changes^{5,6}. The Norte Grande and Central Chile, with longitudinal, fault-bounded valleys, bordered to the east by lines of recent volcanoes^{3,4,7}, contrast with the Norte Chico from which these features are absent, thereby demonstrating that the physiographic provinces also exert a control over tectonism and calc-alkaline magmatism.

Similar, possibly more important, transverse boundaries which coincide with major features in the east-central Pacific, effectively define the northern and southern limits of the central Andes and mark a single, transverse division⁸.

A study of intermediate and deep focus earthquakes in the Japanese arcs⁹ revealed a series of offsets and changes in strike in the deep seismic zone, which is thus effectively divided into a number of 100–300 km long segments. These discontinuities can be correlated with surface geological features, such as: offsets or changes in the strike of the trench axis or of belts of volcanoes; and lines of volcanoes, prominent structures or topographic changes transverse to the arc⁹. It is proposed here that the well known longitudinal subdivisions of Chile, and the boundaries emphasised by Gansser⁸, are comparable to the transverse geological features in Japan and are probably also coincident with discontinuities on the underlying deep seismic zone.

Using the criteria of Carr *et al.*⁹, together with additional geological evidence, I have subdivided the central Andes into tectonic provinces (Fig. 1).

Definition of tectonic segments

Boundary 1 (Fig. 1) is known as the Amotape zone^{7,10,11}, and marks the northern limit of the central Andes⁸. The overall geology changes markedly at this point; to the north, a coastal belt of ophiolitic rocks appears^{8,12}, together with a line of recent stratovolcanoes associated with a longitudinal graben⁷. The boundary coincides with local transverse strikes⁸ and faults¹³, aligned with the Gulf of Guayaquil and the Carnegie Ridge to the west, and the Amazon depression, perhaps an old shield lineament¹¹, to the east.

Boundary 2 approximately coincides with the Huancabamba deflection¹⁴ at a point where the Andes change their strike from north-west to north-north-east.

Transverse strikes have been noted on boundary 3 (ref. 10), which marks the southern limit of the Coastal Cordillera.

Boundary 4 coincides with the Pisco¹⁴ or Abancay^{15,16} deflection and has been proposed as a line of division in the central Andes⁸. It is marked by a major step in the coastline, which indicates the abrupt northward disappearance of the Precambrian formations of the Coastal Cordillera^{17,18}, and by the offshore Nazca Ridge, and a shallowing of the Peru–Chile trench¹⁹. On the boundary there is a marked northward narrowing and change in direction of the Eastern Cordillera, and north-east–south-west striking formations^{16,20}. Important changes in the Mesozoic palaeogeography have also been observed¹⁶.

Boundary 5 is marked by the northern limits of the belt of recent volcanoes and the Altiplano–Puna block.

Boundary 6 is characterised by a change in Andean strike, from north to north-west, and by a northward narrowing of the Eastern Cordillera, where it has been termed the Ichilo fault zone²¹ or line²², or the Arica Elbow line²³. East of the Andean orogen the Precambrian basement is veneered by Cainozoic sediments to the north of the boundary, whereas to the south, Palaeozoic and Cretaceous formations are also present²⁴. The

westward extension of the Arica Elbow line is less apparent but has been proposed^{22,23,25}.

Boundary 8 is so positioned because of the coincidence of a sinuous portion of the Peru–Chile trench¹⁹ with the increase in width of the longitudinal valley (Fig. 1), the northern limit of the north-north-east trending Cordillera Domeyko²⁶, a westward step in the longitudinal belt of recent volcanoes, and an extension of Quaternary volcanoes in an irregular transverse belt extending as far as the Eastern Cordillera, especially in Sud Lipez in southernmost Bolivia.

Boundary 10, between the Norte Grande and the Norte Chico, coincides with the approximate southern limits of the belt of recent volcanoes, the longitudinal valley and the elevated

Fig. 1 The tectonic boundaries proposed for the central Andean volcano-plutonic orogen, in relation to certain physiographic features. a–d, metallogenic belts: a, iron; b, copper–gold–molybdenum; c, copper–lead–zinc–silver; d, tin–tungsten–silver; e, Altiplano–Puna; f, Longitudinal and Central Valleys; x, Location of recent volcanoes; +---+, axis of Peru–Chile trench. Heavy dashed lines are the boundaries between the tectonic segments; numbered as referred to in the text; a sub-script 2 denotes a boundary of only secondary importance.

Altiplano-Puna block²⁷ (Fig. 1). To the south there is a distinctive Cainozoic geomorphological development^{28,29}. The boundary also seems to have controlled the southern limit of widespread volcanism in the Jurassic, and the northern limit of widespread submarine volcanism in the Lower Cretaceous³⁰.

Boundary 13 marks the junction between Central Chile and the Norte Chico. It limits the northernmost extent of the belt of recent volcanoes, of the Central Valley—a Palaeogene feature^{31,32}, of the belt of Upper Tertiary andesitic–basaltic volcanics, and of widespread Precambrian rocks and Palaeozoic intrusives in the Coastal Cordillera²⁶. In Argentina, the boundary controls the southernmost extent of the Precordillera³³ and the Sierra de Córdoba. The boundary also lies at approximately the same latitude as the Chile fracture zone in the east-central Pacific (Fig. 1).

Boundary 16 is the southern limit of the central Andes⁸ and of the Central Valley of Chile (Fig. 1), and lies at the same latitude as the spreading Chile Ridge. It also corresponds to the southern limit of volcanism in Upper Cretaceous, Eocene, late Tertiary and recent time³⁰.

Correlations with seismicity

In order to confirm whether or not the present seismic boundaries in the Andes coincide with the geologically defined boundaries suggested here, and in an attempt to recognise additional boundaries, a study of the latitudinal distribution of intermediate and deep focus earthquakes is necessary. Some information on seismic provinces is, however, available and correlates reasonably well with the tectonic segmentation proposed here. Gajardo and Lomnitz⁵ defined provinces in Chile according to the levels of seismicity measured during a 16 yr period. Some of their boundaries correspond to boundaries 6, 8, 10, 14 and 15 (Fig. 1). Stauder³⁴ defined a similar series of boundaries between distinct seismic provinces, which correspond well to boundaries 6, 9, 10, 14 and 16 (Fig. 1). He also postulated that “the lithospheric slab” is apparently “segmented into a series of tongues that are absorbed independently”. South of boundary 15 there is a shift of major seismicity to an offshore position^{34,35}. Kelleher³⁶ studied the rupture pattern of the shallow part of the seismic zone beneath the Andes. He determined that the zone between boundaries 1 and 3 (Fig. 1) has been aseismic this century, whereas that between boundaries 3 and 5 has experienced large earthquakes, and that between boundaries 13 and 16 has ruptured about once each century along its entire length. He also recognised the intervals between boundaries 5 and 9 and 9 and 13 as distinct seismic provinces.

Nature of tectonic boundaries

As favoured by Carr *et al.*⁹ for the Japanese arcs, I believe that the surface geological discontinuities in the central Andes probably correlate with subjacent seismic discontinuities, and reflect transverse boundary zones between separate segments of oceanic lithosphere which are subducted as individual units, perhaps even at different rates. The segmentation of the subduction zone is presumed to result from stresses created by the underthrusting of a cap-like slab of lithosphere, and the pattern produced may well be self-perpetuating. Transform faults, which divide up the oceanic lithosphere into a series of strips, may also play a part in the production of the segments. Shield lineaments could also be involved at the boundaries at which changes in Andean strike are apparent⁸, but they probably exert only a subsidiary influence.

The surface manifestations of the tectonic boundaries suggest that the magnitudes, and perhaps the histories, of their activity

are different. Furthermore, some boundaries (such as No. 13) seem to be fairly abrupt, and others (such as No. 10) more diffuse. It is not clear whether tectonic boundaries are relatively permanent features or whether they tend to migrate slowly or jump around with time. The fact that some of the present boundaries apparently occupied the same positions in early Cainozoic and even Mesozoic times, however, implies some degree of stability, or at least of repeated reactivation.

Although the discontinuities at the surface and on the subduction zone probably coincide, it does not necessarily mean that they are connected by major fault zones. Rather, I believe that the crustal segments overlying the various segments of the sinking slab have been subjected to similar, but clearly distinct, tectonic, geomorphological, magmatic and metallogenic regimes, with zones of transition between them. Consequently, the wholesale extrapolation of geological histories along the lengths of volcano–plutonic orogens should be avoided.

Implications for magmatism

Across the central Andes, post-Triassic calc-alkaline magmas, of probable subduction zone origin^{1,2,37,38}, have been emplaced episodically upon and within the continental crust as a series of discrete pulses^{30,39,40}. Each magmatic pulse has given rise to long, narrow belts of intrusive and extrusive rocks roughly parallel to the continental margin. Successive belts young eastwards in the western and central parts of the orogen^{30,39,40}, as is common in volcano–plutonic orogens⁴¹, whereas little lateral migration of magmatism took place in a second locus of activity along the eastern margin of the Andes at latitudes 14°–24°S.

Radiometric age data^{30,40,42}, together with the mapped distribution of the magmatic belts both in the west and centre of the orogen and further east, support the concept that the belts are not longitudinally continuous. Therefore, magmatism in any particular tectonic segment can be expected to possess its own unique episodicity and spatial distribution, replaced by similar but clearly distinguishable regimes to the north and south. Clear discontinuities in belts of intrusive rocks have been recognised at boundaries 2, 3, 4, 5, 6, 7, 8, 10, 13 and 14, and volcanism, particularly recent activity, only occurs in certain segments at any one time.

Although magmatism in the North American Cordillera is locally episodic, it is essentially continuous if viewed over the full extent of the orogen⁴³. Meso–Cainozoic intrusive epochs cannot be correlated throughout the orogen⁴⁴. This may be simply explained if it is accepted that age patterns are only valid within individual tectonic segments.

Implications for metallogeny

The majority of the principal ore deposits in the central Andes have an inherent spatial and temporal relationship with the magmatic activity, and they are believed to derive their metal contents from the underlying subduction zone^{45–47}. Thus, it might be expected that the regional metallogeny varies between segments. An examination of the distribution of post-Palaeozoic metallogenic belts in the central Andes (Fig. 1, and ref. 46) reveals a coastal belt rich in iron, bordered to the east by a copper–(gold–molybdenum) belt, a copper–lead–zinc–silver belt, and, in the central part of the region, a tin–(tungsten–silver) belt. When tectonic boundaries are crossed these metallogenic belts tend either to end or to undergo changes in their characteristics, including: second-order variations in their metal contents; changes in their widths; and changes in the ages, types and sizes of deposits. The tin belt is restricted to three segments enclosed by boundaries 5 and 8 (Fig. 1), and is subdivided into a narrow, northern segment dominated by vein-type tin–tungsten deposits related to Mesozoic and

early Miocene batholiths, and a broader, southern part in which tin and tin-silver deposits of vein and porphyry⁴⁹ types are largely related to late Tertiary subvolcanic stocks⁵⁰⁻⁵². Contact-metamorphic and vein type iron deposits are located in the coastal zone between boundaries 1 and 2, 4 and 6, and 9 and 12 (refs 30, 53, 54). The copper belt extends northwards from boundary 15 (ref. 53), but loses a good deal of its importance north of boundary 4. The polymetallic province is particularly enriched in silver north of boundary 1 (ref. 13), but is most important, despite its narrowness, from boundary 2 to boundary 4. From boundary 4 to boundary 5 the metal content is anomalous and lead, zinc and silver are overshadowed by copper and iron (Fig. 1, and ref. 54), and south of boundary 8 mineralisation is rather sparse and dominated by copper⁵⁵. Within the copper belt the termination of long lines of distinctive ore types is also controlled by tectonic boundaries. Examples are the chalcopyrite-magnetite-actinolite veins that are known between boundaries 8 and 12 (ref. 53) and the disseminated, stratiform (manto-type) copper deposits in Jurassic volcanics from boundary 8 to boundary 10 (ref. 56). The porphyry copper deposits in the central Andes decrease in age eastwards³⁸ but, in addition, the major deposits change in age along the strike, so that Palaeocene deposits are dominant between boundaries 5 and 6 (refs 40 and 57), late Eocene-Oligocene deposits are dominant between boundaries 7 and 10, and late Miocene-Pliocene deposits are dominant between boundaries 12 and 14 (ref. 58). It is concluded that the definition of metallogenic segments is an important facet of the metallogenic characterisation of volcano-plutonic orogens and effectively explains the longitudinal variability of their metallogeny.

Mineral exploration

The mapping of metallogenic segmentation in both young and ancient volcano-plutonic orogens is clearly of paramount importance in the planning of mineral exploration programmes since metal contents, ore types and even economic importance change at tectonic boundaries.

Although a conclusive statement cannot be made at present, there is evidence from the central Andes that some major ore deposits tend to be located on or close to tectonic boundaries; the Chuquicamata and Río Blanco-Disputada porphyry copper deposits lie on boundaries 8 and 13, and the Oruro and Potosí porphyry tin deposits on boundaries 6 and 7. If magmas and their related metals are derived from the vicinity of the subduction zone, then this possibility seems to be more reasonable than the proposal that the locations of major ore deposits are controlled by megalineaments and their inter-sections (ref. 59 and 60), especially as lineaments in the central Andes are commonly at high angles to the tectonic boundaries⁶¹⁻⁶³ and are relatively superficial flaws in the upper continental crust.

Preparation of this article was commenced during tenure of a Shell postdoctoral Research Fellowship. Dr E. J. Cobbing read the manuscript.

Structure of yeast phenylalanine tRNA at 3 Å resolution

J. D. Robertus*, Jane E. Ladner, J. T. Finch, Daniela Rhodes, R. S. Brown, B. F. C. Clark & A. Klug

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

The structure of a tRNA has been determined by isomorphous replacement. Some of the interactions which maintain the tertiary structure are of a novel type. Our model differs significantly from one which has recently been proposed.

TRANSFER RNA plays a central part in protein biosynthesis. Each molecule carries an amino acid to the ribosome and decodes the genetic information in messenger RNA, to put the sequence of amino acids in order. Since tRNA was first crystallised¹ we have looked² for a species which would give crystals suitable for high resolution X-ray analysis. Two years ago we reported³ the results of systematic crystallisation studies of yeast phenylalanine tRNA which yielded such crystals. Here we report the solution of the structure to 3 Å resolution using the method of isomorphous replacement. The map obtained is of sufficient quality to trace the ribose-phosphate chain over most of its course. In addition to the base pairs of the clover leaf formula (Fig. 1), we have found several interactions which help to maintain the tertiary structure. These are additional base pairs or triples, mostly not of the Watson-Crick type, and also a variety of stacking interactions. Most of these interactions can be related to invariant features of the nucleotide sequence of tRNA. The model is in accord with the chemical reactivities of different tRNAs.

The tRNA species studied here is the same as that for which a model has been recently proposed by a group at MIT⁴. Although the crystal forms are different, the molecular structure is expected to be the same. The two models differ, however, in certain major respects. Most of the nucleotide residues are differently placed in the two models, and none of the essential tertiary interactions are present in the MIT model.

X-ray analysis

The unit cell⁵ is monoclinic, space group P2₁ with $a=56.0$ Å, $b=33.4$ Å, $c=63.0$ Å and $\beta=90.4^\circ$. All the heavy atom derivatives were made by soaking the crystals in solutions containing various cations or complex ions. The addition of almost any heavy atom produced changes in the angle β , but this change could be minimised by keeping the crystals in a stream of air at 4° C (ref. 5). Table 1 lists the heavy atoms which gave good isomorphous derivatives, together with their occupancies and coordinates. The data were collected on a diffractometer. No significant deterioration (<15% in the intensity of monitored reflections) was observed during data collection, so that a single crystal could be used for each derivative. The quality of the crystal data is only moderate compared with that of some proteins of similar size. We attribute this not to intrinsic disorder in the crystal, but to the difficulty of handling the thin plate-

like crystals which easily crack or buckle. Heavy atom refinements were carried out by least squares (Table 1). The absolute hand was determined from the anomalous scattering of the samarium derivative. The electron density map was computed on a 1 Å grid. Sections perpendicular to x were assembled at a scale of 2 cm per Å in a Richards box⁶, and Kendrew skeletal parts were used to build the model.

Electron density map

As with a protein at the same resolution, the electron density map by itself does not suffice to solve the structure, but when combined with the nucleotide sequence and the known stereochemistry of the residues, it does provide enough information for the construction of an atomic model. In a protein map the polypeptide backbone is however visible as a continuous chain of high density and the side chains as bulges, many of which are sufficiently characteristic in

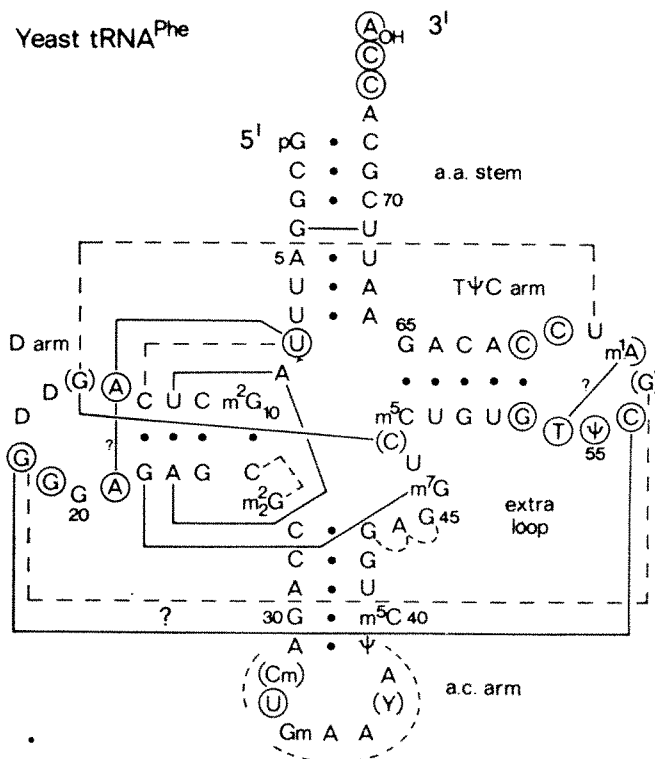

Fig. 1 The sequence of yeast tRNA^{Phe} arranged in the clover leaf formula²¹. An arm of the clover leaf is made up of a double helical stem and a single stranded loop. Bases which are invariant in all tRNA sequences²² are circled; semi-invariants, that is, purines or pyrimidines exclusively, are bracketed. Nucleotides which are base paired in the tertiary structure are joined by solid lines, and those which stack on each other by dashed lines.

*Present address: Clayton Biochemical Institute, Department of Chemistry, University of Texas, Austin, Texas 78712.

Fig. 2 A composite of four electron density map sections at $x=48-51$ Å. This includes a strand of the D stem. Most of the electron density not identified belongs to adjacent molecules or to cations. The heavy white lines represent the skeleton of the molecule. R21 lies just outside the sections shown. P: phosphate group; R: ribose; S: probably spermine. The grid squares are of side 10 Å. This region corresponds to part of Fig. 4 of the MIT paper⁴.

size and shape to be identified and hence related to the amino acid sequence. In contrast, in RNA there are essentially only two types of residue, purine and pyrimidine, not easily distinguishable from each other. Moreover the bases have a total mass similar to the phosphates and riboses, and, when base-paired to bridge two pieces of backbone not in a double helical region, they give that part of the map more the character of a network than of a dominant single chain standing out from a lower landscape. The situation is further complicated by the presence of numerous cations, Mg^{2+} , Na^+ or spermine, many hydrated and held in fixed positions. In tracing the ribose phosphate chain from the electron density map, the most important constraint comes from the expectation of finding the four double helical stems of the clover leaf formula and the necessity of joining them correctly. The electron density corresponding to the chain was generally clear in the double helical regions. In most areas clearly resolved peaks could be seen for each ribose and for each phosphate, which could usually be distinguished by their shape and by the connectivity of the density: the phosphate groups tend to be spherical while ribose density is more disk-like. The angles made between the groups are also very characteristic, giving a distinct sugar-phosphate stagger which is difficult to misinterpret (Fig. 2). Fitting the model in such regions fixed the polarity of the chain unambiguously.

The assignment of the helical stems could be checked because in some base pairs the purine can be distinguished from the pyrimidine, and wherever a decision can be made, the result agrees with the sequence (Fig. 3a). Confirmation of the helix assignment comes from chemical work on the platinum derivative. Fingerprints of various enzyme digests of the tRNA reacted with the platinum compound showed that the metal was bound in the fragment 34 to 39, agreeing with the position found for it in the model.

In regions of the map which do not contain double helical segments, the connectivity and polarity of the chain is more difficult to determine from electron density alone. In some places the thermal motion or disorder smears out the phosphate or ribose peaks. Here it is important to use conformational information^{7,8} obtained from single crystal structure analysis of oligonucleotides. In the end we were able to trace the whole chain except for several nucleotides

in the D and T ψ C loops. These lie close together in one corner of the molecule and are also in tight contact with the same loops of two other symmetry-related molecules. Here the density is strong but broken up and we have not been able to arrive at an unambiguous chain tracing. The stretches in question are however confined to a small region of the map so that, whatever the final details, their structure will be constrained within the bounds proposed in our model.

Z is the occupancy. B is the isotropic temperature factor. n is the number of reflections used in the refinement. f_H is the calculated heavy atom contribution to the structure factor. E is the closure error, $|f_H(\text{observed}) - f_H(\text{calculated})|$. P is the phasing power, the ratio of the two previous columns. The Os derivative was refined in three shells⁹ because of changing occupancy; the Z quoted is the mean. The mean figure of merit for 4,838 reflections = 0.67. The mean standard deviation in $|F|$ of the reflections measured more than once during data collection was 6% of the mean $|F|$ for the native crystal, and somewhat higher for the derivatives. Structure factors and intensities were calculated using hand-measured coordinates of residues 1-17, 21-54 and 58-76. The classical R-factor on $|F|$ s is 0.468 and the correlation coefficient between calculated and observed intensities is 0.567.

Since we were not always able to distinguish purines from pyrimidines even within helical regions, the sequence data were initially of little help in solving the atomic structure, but as the helical regions and sequence numbering became established, features of density corresponding to the bases became interpretable. For example, the electron density at base position 26 was of a shape consistent with a twice

Fig. 3 Parts of skew slices of the electron density map showing the density distribution in the planes of certain base pairs or base triples. Each slice comprises two sections 1 Å apart (full and dotted contours). The superposed skeleton is taken from the coordinates of the unrefined model. The ribose groups generally lie out of the planes of the sections. *a*, A Watson-Crick base pair from the TψC stem. Additional peaks can be seen in the neighbourhood of non-bonded polar groups, probably water molecules or cations. *b*, The unusual base pair G15-C48 with the glycosyl bonds in the *trans* position. The peak above the amino group of C48 may be a cation or water molecule. *c*, A base triple from the augmented D helix, 13-22-46.

methylated G, and so provided a valuable marker in the model building. Also, the shape of the electron density for the G15 base (Fig. 3*b*) gave us confidence that the base pair 15-48 was of the unorthodox type to be discussed below.

Some features of the cation distribution also began to emerge. An interesting example is an ion found chelated between the amino groups of G25 and G45 and the oxygens of phosphates 23 and 24. This may be one of the tightly bound magnesium ions which seem to be an integral part of the native structure⁹.

Molecular structure and tertiary interactions

Figures 4 and 5 are photographs of the molecular model. The anticodon is at the upper right, the amino acid stem at the upper left, with the TψC loop in the bottom left corner. The relative arrangement of the double helical segments is indicated schematically in Fig. 6 which also shows the topology of the connections made in the tertiary structure. (These tertiary interactions are also indicated in Fig. 1.) All but seven of the bases are represented in the diagram. Base pairs additional to those in the stems are shown as dotted lines. As might be expected¹⁰, they are protected from water by stacking or intercalation. The stacking and intercalation of unpaired bases is also indicated. The region shown dashed is the TψC loop-D loop corner where we have not been able to determine the structure unambiguously.

The amino acid stem is stacked on the TψC stem in such a way that a long double helix of 12 base pairs is formed in which one of the ribose phosphate chains (72-61) is not interrupted. In the companion strand there is a break between nucleotides 7 and 49, though this does not seem to disturb the overall perfection of the long double helix. But the sharp turn made at the 50-49-48 corner involves the close approach of phosphates (~5 Å), and the details are subject to revision at higher resolution. The G-U base pair 4-69 also seems to be made without any major disturbance to the helix, at least at this resolution. The long double helix is right handed, has its bases tilted to the axis, and the axial distance between residues 61 and 72 is 30 Å so that the repeat per residue along the helix axis is 2.8 Å. The helix is therefore of the A form. At one end of the helix are stacked the unpaired bases A73 and C74, and at the other end, T54 which is also paired to another base in the TψC loop.

In contrast to the amino acid and TψC stems, the D stem and the anticodon stems are only approximately collinear, lying 20° from each other. The two together, with nucleotide 26 in between, form a long imperfect double helix which lies roughly at right angles to the first long helix, and meets it at its middle, so that the two are arranged rather as the letter T.

The D stem is guyed at the T join to the long double helix by part of the variable loop (residues 44-48) and by the stretch 8-9 which connects one strand of the amino acid stem to one strand of the D stem. This stretch, which is two nucleotides long in all tRNAs, is fully extended in the model, allowing it to span the length of the D stem. A9 makes a base pair, of the type found in poly(A)¹², with A23, which is paired to U12 in the D stem, so that all three together form a base triple. A base pair of the reverse Hoogsteen type¹³ is formed between U8 and A14, both of which are invariant nucleotides. U8 is then stacked on C13 and in the right orientation to allow the photoreaction observed by Yaniv¹⁴. On the pair 8-14 is stacked an unusual base pair formed between G15 of the D loop and C48 of the extra loop (Fig. 3*b*). These two bases form the correlated pair noticed by Levitt¹⁵ and might have been expected to form a Watson-Crick pair. We discuss this question below.

Thus the D stem has been augmented along its length by the non-standard base pairs 8-14 and 15-48. On the end of

this again there is stacked a single base for which there is strong density coming up from the T ψ C loop. This is either U59 or A58 depending on the resolution of the ambiguity discussed below. This base seems to mediate the abutting of the augmented D stem on to the long double helix formed by the amino acid and T ψ C stems, by fitting into the large groove and acting as a sort of peg to help hold the two perpendicular helices together. Apart from the connection 15–48, the D arm is also connected to the extra arm at a further point: G46 is base paired to G22, so that there is a second base triple 46–22–13 (Fig. 3c) in the structure. At the other end of the D stem is stacked the unpaired base G26, so that finally the augmented D helix contains a stack eight base spacings long. The translation per residue is about 3 Å so that this helix is closer to the A' form of RNA¹¹.

Continuing around the D loop, nucleotides D16 and D17 arch outwards from the body of the molecule. The invariant pair of residues G18 and G19 come into close contact with the T ψ C loop in a manner to be described,

with the base of 26 lying in the bearing formed by 44 and 45. A result of the tilt is that the major groove of the long, imperfect double helical segment formed by the anticodon and D stems is now some 5 Å narrower than for the more perfect double helix formed by the amino acid and T ψ C stems.

The anticodon loop itself is stacked on the 3' side roughly in the manner suggested by Fuller and Hodgson¹⁷. The density is weak in this region so we cannot be confident of the position of the bases but it seems that base 38 points inwards, 37 more outwards and finally the three bases of the anticodon protrude outwards from a quasihelical backbone. Here O2' of ribose 35 comes close to O1' of ribose 36, suggesting a hydrogen bond, and there is a similar linkage between 36 and 37. We can see no special structural rôle for the Y base 37. On the 5' side of the loop the bases 32 and 33 are also stacked but seem to face inwards rather than outwards⁷. This is made possible by kinks in the backbone at the two residues 32 and 34 methylated in the O2' position.

Fig. 4 A photograph of the model taken in a direction roughly perpendicular to the plane of the T made by the two long double helical segments (see Fig. 6). The geometrical shape of the T is somewhat obscured by the chains of the T ψ C and extra loops.

whereas G20, which is variable, comes up again close to the other variable nucleotides 16 and 17 and points outwards. The exposed position of these three residues is consistent with their chemical reactivity¹⁸. A21, which is invariant, stacks and intercalates between the base pairs 13–22 and 15–48. It lies in the plane of the base pair 8–14 but the density does not seem to permit another base triple here, tantalisingly close as it is. Possibly A21 forms a hydrogen bond with the ribose of 8. It may be that in other species of tRNA this would be a base triple formed by the three invariant bases, 8, 14 and 21.

The axis of the anticodon stem is not only tilted by about 20° to the D stem, but is also dislocated by about 5 Å from the line of the D stem. Thus the bases A44 and G45 are stacked on the last base pair 27–43 of the anticodon stem, but lie below the right hand end of the augmented D helix, with G26 partially intercalating between them. All tRNAs have a single unpaired base in position 26 and the structure suggests that this feature is associated with the tilting of the anticodon stem relative to the D helix. Indeed, the structure here presents the appearance of a hinge,

We have not been able to make an unambiguous tracing of the chain in the T ψ C loop region, but there are some features of which we are reasonably certain. T54 is paired to another base in the same loop, a base from this loop stacks on the end of the augmented double helix and G57 lies close to G18 and G19 of the D loop. We have found two alternative configurations, both of which are stereochemically acceptable. In the first version, T54 is Hoogsteen paired with A58, U59 stacks on G15, G57 intercalates between the bases of G18 and G19, and C56 is close enough to G18 or G19 to form a base pair. In the second version, the base which pairs with T54 is C60 and that which stacks on the augmented D helix is A58. The three bases G18, G19 and G57 still form a stack, but the order is now 18–19–57 rather than 18–57–19. This stacking proposed for the three invariant Gs is a novel and certainly unexpected tertiary interaction, but it remains to be proved correct. In both versions G20 is in the accessible part of the D loop, in the neighbourhood of D16 and D17.

At the 3' end, A73 and C74 are stacked on the end of the amino acid stem but the final ACCA stretch swings

across the unit cell and packs between the anticodon stems of two other symmetry related molecules. These latter stems are 33 Å apart in the *y* direction and the gap is nicely filled by this ACCA chain from the first molecule.

Relation to the MIT model

The relationship between the monoclinic form and the orthorhombic form studied⁴ at MIT is *a, b, c* (MRC) → *b, -a, c* (MIT). In view of the similarity of X-ray intensities³ the contents of half the orthorhombic unit cell should superpose on the whole monoclinic cell when aligned on the common 2₁ axes. We have found the relative translation from the lanthanide positions common to the two crystals, and the map sections published by the MIT group⁴ are generally similar to the corresponding sections in our map, but there are everywhere significant differences in detail and major differences in interpretation.

The overall shape of our model is similar to that proposed by the MIT group and we seem to agree about the relative positions of the anticodon, amino acid and TψC stems, but there is complete disagreement about the orientation of the central D stem. This difference means that almost all the connections to the remainder of the molecule must be radically different in the two models. We have been able to define a number of tertiary interactions in the molecular centre holding it rigid, whereas the only tertiary interaction proposed in the MIT model is that between the correlated base pair 15-48 which is, by implication, of the Watson-Crick type, contrary to our findings. In our model the D helix lies approximately normal to the TψC stem, that is, parallel to the long *c* axis, and the base pairs lie in planes roughly perpendicular to *c* (Fig. 4). The density corresponding to the bases is quite unequivocal in this respect. But in

(MIT Fig. 5) the sugar-phosphate stagger and the bases have not been fitted correctly to the density. It is presumably these misfittings which have led the MIT workers to state⁴ that the double helices in the stems are not regular and cannot be assigned to one of the standard classes. We find helices which are regular at the resolution of the map.

There seem to be many other differences between the two structures, though they mostly involve the loop regions, where the MIT chain tracing is presented as tentative. Thus, in the MIT model the large Y base 37 extends across the major groove between the anticodon and D double helices to touch a phosphate on the D stem, whereas we have found the Y base positioned inside the anticodon loop. The structure of the anticodon loop is not described in the MIT paper, but from the picture of their model it is clearly not the ordered structure which we have built. Likewise, the interactions formed by the extra loop in our model do not seem to be made in the MIT model, and no others are described. In the MIT model, many of the bases in the TψC loop and the distal part of the D loop seem to be exposed, whereas in our model, despite the ambiguity mentioned earlier, they are stacked or otherwise not accessible to chemical attack, as is observed¹⁰.

Conclusions

The molecule can be described as consisting of three major substructures (Fig. 6). These are: (1) the long double helix formed by the amino acid and TψC stems stacking on top of each other; (2) the augmented D helix, forming the "thorax" of the molecule: this consists of the D stem augmented by part of its own loop and interlocked with both the stretch 8-9 and with part of the extra loop; (3) the anticodon stem, tilted off by about 20° at the other end

Fig. 5 A stereophoto-graph of a Kendrew skeletal model (2 cm per Å) of yeast tRNA^{Phe} built to fit the 3 Å map. The amino acid stem is at the upper left, and the anticodon at upper right. The TψC loop and distal part of the D loop are at the bottom left. The model is viewed approximately in the +*x* direction with +*z* running approximately from right to left. The whole CCA end at upper left is not in the frame of the photograph.

the MIT model the direction of the D stem is roughly perpendicular to *c*, as can be seen in the MIT Fig. 2 and from the disposition of the base pair 13-22 in their Fig. 4. Likewise the connecting sequence 8 and 9 runs horizontally in our model and more or less vertically in the MIT model.

Comparing our Fig. 4 with the corresponding area in Fig. 4 of the MIT paper, one sees that the only assignment here common to the two models is ribose 61. The MIT model has the base pair 13-22 placed in a way quite inconsistent with our density map and in effect forces a connection between residues 15 and 23. The assignment of the nucleotide sequence on the D stem is thus incorrect by two residues on one strand and by one on the other. We note that the other double helical stems have also not been fitted correctly in the MIT model²⁵. Thus, the MIT workers have placed R26 (their Fig. 3) where we have R27, so that the phase of the nucleotide sequence is incorrect and the base pair 42-28 is wrongly fitted to the density. This means that the tilt of all the bases in the anticodon helix must be wrong. Likewise we find that in the TψC helical stem

of the D stem and possibly hinged to it. These three main helical directions correspond well to the three largest peaks in Levitt's search of the X-ray intensities of the native crystal¹⁸: (1) corresponds to the peak at (−60°, −35°), (2) to (−15°, 0°), and (3) to (−35°, 0°), where the first value gives the rotation angle about *a*, and the second about *b*. The angle between (1) and (2) is then 103°.

To these substructures are adjoined other parts with clear functional rôles: (4) the ACCA sequence, at one end of (1), to carry the amino acid; (5) at the other end, the almost invariant TψC loop tightly folded and connected to the two invariant Gs 18 and 19 of the D loop, probably forming a ribosomal recognition site common to all tRNAs. The most variable nucleotides in the D loop, 16, 17 and 20, form (6) a patch flanking the augmented D helix (on the far side in Fig. 5); this may be an enzyme discrimination site, different for different tRNAs. There is also the region (7), on the other side of the D helix here consisting of a few variable bases; this can be assigned to the large extra arm which is present in other classes of tRNA, presumably for discrimi-

nation. Finally there is (8), the anticodon loop carrying the anticodon itself. This loop is stacked on the 3' side of the anticodon stem, but it has been suggested to us by Dr F. H. C. Crick that, if indeed the join between the anticodon stem and the augmented D helix functions as a hinge, then the conformation of the loop might possibly alter during protein synthesis, in the manner proposed by Woese¹⁹.

The unusual base pair 15-48 requires some discussion. Levitt¹⁵ noticed that 15 is always either G or A with 48 respectively C or U. There is only one exception²⁰ to this rule so far observed, in glycine tRNA where the bases are A and C. It is at first sight rather surprising that the nucleotides in these positions do not form a standard base pair. But if they did, one might expect the purine and pyrimidine to be exchanged between the two positions in some tRNAs. The fact is that the purine is always in position 15 and the pyrimidine always in 48. This speaks

example of a set of correlated base changes. Most class 1 sequences also have U12, A23 and A9 and can make the second triple base described above. There is a subclass which has G12, C23 and G9, but G9 can make only one hydrogen bond to C23, unless there is a different tautomeric form or adopts a syn conformation. There is always the possibility of a third triple interaction using the invariants U8-A14-A21 as mentioned above.

We should like to emphasise that the model is in good accord with the results of a companion study of the chemical reactivity of yeast tRNA^{Phe} as already reported by us²⁶. The model is stereochemically sound within the physical limits of building with skeletal wire components, and is now being refined. Data to higher resolution are also being collected.

We thank Dr M. J. Cleare of Johnson, Matthey & Co. Ltd. for the gift of *trans*-dichlorodiammine platinum and him and Dr B. Johnson for advice. We thank Dr M. Levitt for help and for his earlier model building, and Mrs S. Porter for help. J. D. R. held a National Institutes of Health post-doctoral fellowship.

Note added in proof: The MIT workers have now revised their model (Rich, personal communication).

Received June 14; revised July 10, 1974.

Fig. 6 A schematic diagram of the tertiary structure of yeast tRNA^{Phe}. The ribose-phosphate backbone is represented by a continuous line, except where there is ambiguity when it is shown dashed. Base pairs in the double helical stems are represented by long light lines, and non-paired bases by shorter lines. Many of the latter stack as indicated; those which do not are drawn at an angle, for example 16, 17 and 47. Base pairs additional to those in the clover leaf formula are indicated by dotted lines. The region marked f is explained in the text.

for an asymmetry in the bonding between the two chains, such as we have described. It is not possible to interchange the purine and pyrimidine and maintain the same disposition of the glycosyl bonds. Moreover, a 'reverse Watson-Crick' A-U pair can be accommodated here with almost the same *trans* arrangement of glycosyl bonds. It would seem that this nonsymmetrical pair of glycosyl bonds is required by the particular demand of connecting two locally parallel chains not related by any kind of dyad. Models of all ten combinations of base pairs in which the glycosyl bonds are *trans* to each other show that the two pairs G-C and A-U are the most similar, distinct from all the other possibilities.

We believe that our model can accommodate all tRNA sequences of the class 1 type¹⁵, and that many of its features will be retained in the other two classes. Class 1 has four bases in the D stem and five nucleotides in the extra loop, and all sequences can be fitted into the model without rearrangement. Most sequences have C13, G22 and G46 and hence can make the base triple 13-22-46. One of the remaining species has U13-A22, but 46 is now an A, and this combination can form a base triple with the three glycosyl bonds in the same positions. We thus have another

letters to nature

A model of the magnetospheric substorm

It is generally recognised that the Earth's magnetic tail and the plasma sheet play a vital role in the processes responsible for the observational phenomenon known as the magnetospheric substorm. Many different models¹⁻⁵ of substorm behaviour have been described with differing degrees of success, and to propose another requires some justification. A new model, if it is to be useful, must do two things. It must be specific enough to make quantitative theoretical analysis possible, and it must fit the morphological features more completely or in a more elegant way than other models. In addition, it should be distinctive enough from other models to be separated from them by observational tests. I believe the model presented here has those properties.

The main features of the model are that the plasma sheet is formed on closed field lines and moves inward during the growth phase; the magnetic field line reconnection across the neutral sheet occurs on the lobe field lines, is essentially continuous but is not directly responsible for the expansion phase; and the expansion phase is the result of an interchange type of instability with the plasma sheet expanding on to empty, closed field lines.

The two principal regions in the tail—the plasma sheet and the lobes of the tail connected to the polar caps—are easily distinguished by their particle populations. The plasma sheet is denser and hotter than the lobe plasma⁶ and its energy density is of the same order as its magnetic energy density. The boundary between the two is normally not more than $1 R_e$ thick^{7,8}. One possible reason for the well defined boundary is that there is a source mechanism which only injects particles on plasma sheet field lines⁵. Alternatively, lobe field lines can be open allowing

plasma to escape down the tail, with the plasma sheet trapped on closed field lines⁹. I shall discuss the consequences of the latter.

A convenient starting point for the model substorm sequence is illustrated in Fig. 1a. The plasma sheet occupies all the closed field lines and at its end there is a neutral sheet which extends out of the plane of the paper on both sides. Suppose that the plasma flows towards the neutral sheet under the influence of an electric field (Fig. 1b). The open magnetic field lines of the tail would be reconnected at the neutral sheet at a steady rate. On the Earthward side of the neutral sheet the electric field would convect the plasma inward and accelerate the particles¹⁰. On the far side of the neutral sheet the plasma would be accelerated away from the Earth and gets lost down the tail. The important feature is that lobe field lines thus become reconnected and form closed field lines outside the plasma sheet (Fig. 1b). The plasma sheet, which contains relatively hot, dense plasma, becomes surrounded by closed field lines almost devoid of plasma in comparison. The magnetic field strength outside the plasma sheet would have to be stronger than inside in order to maintain a pressure balance across the boundary. The inward convection would continue (forming the growth phase of the substorm) until the plasma sheet boundary became unstable to a form of interchange instability. As a result the plasma would expand outwards to fill all the closed ex-lobe field lines and the magnetic field strength inside the plasma sheet would increase by a compressional wave propagating inwards from the position of the boundary. This, of course, is the expansion phase of the substorm (Fig. 1c). It leaves a region of turbulent plasma which would eventually thermalise during the recovery phase (Fig. 1d), returning the plasma to the starting point. The inward convection would continue during the recovery phase and may generate another substorm before the original sequence is complete.

The most important magnetospheric feature in this model is the outer boundary of the plasma sheet which initially convects inward stably and later becomes grossly unstable. There are plausible reasons why this should occur. If the model is to make any observational sense the quiet auroral arcs of the growth phase must connect to this boundary. Thus, there is high conductivity strip through the ionosphere on the field lines that pass through the boundary. That helps to stabilise the boundary by short circuiting the electric field of the developing instability. The expansion phase is triggered by the current, which is aligned with the field, becoming too large for the plasma to carry in a stable manner¹¹.

The outer boundary of the plasma sheet is likely to have a complex structure during any magnetospheric convection. The convective velocity, $\vec{V} = -(\vec{E} \times \vec{B})/B^2$, normal to the boundary must be continuous; therefore, because B changes, there must also be a change in the electric field as the boundary is crossed. The simple fluid concept of convective flow is quite inadequate to analyse that situation. It is necessary to take into account the three-dimensional nature of the boundary, currents aligned with the field, and the possibility of electric fields parallel to the magnetic field. It is thus not yet possible to project the electric field discontinuity at the boundary of the plasma sheet in the equatorial region down the field lines to the ionosphere to see whether it matches the electric field reversal region observed by low altitude satellites¹². A detailed theoretical analysis of the boundary is of crucial importance.

The source of the electric field must be considered. The field—

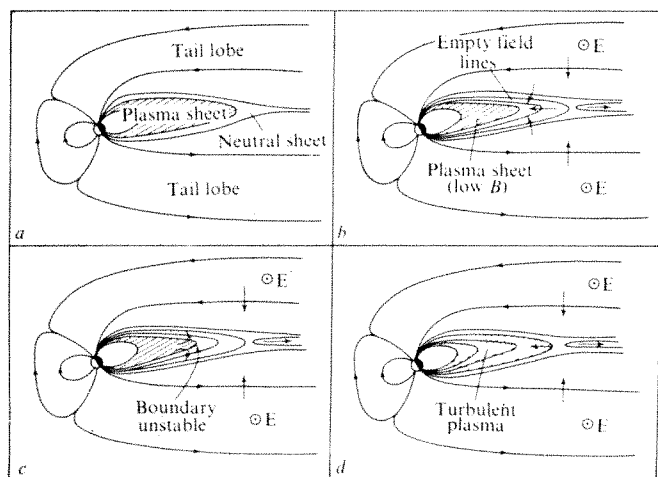

Fig. 1 *a* Basic configuration of the magnetosphere; *b*, the growth phase of the substorm, showing inward convection and reconnection; *c*, the expansion phase, caused by an interchange instability at the outer boundary of the plasma sheet; *d*, the recovery phase during which the turbulent plasma gradually thermalises. Arrows indicate plasma flow and the field strength in the lobes is not intended to be represented by the density of field lines; E , electric field, directed perpendicular to the plane of the page.

line reconnection takes place on lobe field lines and so the following equation, derived by Alfvén¹³⁻¹⁵ on the basis of self consistency between fields and currents, should be at least approximately true. It relates the total electric potential ϕ across the tail, to the field strength B_x and particle density N .

$$\phi = B_x^2 / 4\pi Ne$$

Thus the crosstail electric field is determined by the field strength, B_x , in the tail. B_x is controlled by the total magnetic flux in the tail and the configuration of the magnetopause¹⁹. There should be a direct relationship between energy input to the magnetosphere in the form of substorm activity and the magnetic field strength in the tail¹⁶.

The model obviously satisfies many of the gross morphological features of the magnetospheric substorm. The inward movement of the plasma sheet and the motion of quiet auroral arcs towards the equator are natural features. The outward movement of the plasma sheet and the inward magnetic field compression wave during the substorm expansion phase are directly related through the interchange nature of the instability. The poleward expansion of the aurora during breakup is also explained. It can easily accommodate such features as a multiple substorm onset¹⁷ because the boundary could become unstable over a range of longitudes. There is one auroral feature which does not seem to fit easily into the model—the multiple arc system. It has been reported¹⁸ that the most vigorous breakups occur when they are initiated on the arc nearest to the equator, and not on that furthest from the equator, as may be expected in the model.

There is one morphological feature of this model which differentiates it from most other models¹⁻⁵. If the model is correct it should be possible to cross the neutral sheet, or the region where the magnetic field along the tail changes sign, without detecting the plasma sheet before the onset of a substorm.

Lunar electrical conductivity

THE lunar magnetometer experiment¹ has made important contributions to studies of the lunar interior. The magnetic fluctuation data can be used to estimate the structure of lunar electrical conductivity because it allows comparisons of predicted and observed lunar electromagnetic responses. There are many complications in the correct computation of predicted responses, and approximations are always used. There has been a gradual evolution of models, each improvement including more and more complications, with resultant changes in the estimated conductivities. The first models² had a solar wind incident on the Moon from all sides, in order to approximate the front side lunar response. The backside data was modelled by a Moon in a vacuum¹. Improvements in the front side response were made by incorporating the effects of a finite solar wind velocity³. Previous calculations on a cylindrical model⁴ indicated that the presence of the void region behind the Moon could also modify the sunlit side response. Formal solutions to the electromagnetic problem in such a geometry have been presented⁵.

We have carried out numerical inversions of the lunar electromagnetic response, incorporating in the calculations a void region behind the Moon. We used two different numerical methods. They both gave similar results, although one method is definitely superior in its ability to satisfy the boundary conditions near the limb of the void region. This method consists of using a series of electric and magnetic multipoles, situated at the centre of the Moon, in order to express the field in the void region, which is caused by currents and charges inside the Moon and on its sunlit surface. By using dual Fourier-Bessel series⁶, we can associate to each multipole a series of spherical TE and TM modes that satisfy the boundary conditions on the surface of the cylinder. The amplitude of each multipole is then determined by applying the boundary conditions on the lunar surface.

The inclusion of the void region behind the Moon substantially lessens the predicted lunar response on the sunlit

Fig. 1 The theoretical amplitude of the transfer function obtained by considering the void region behind the moon (x), and that obtained by assuming the void to be filled with plasma (O). Δ , Data values.

side, especially at shorter periods (Fig. 1). This effect occurs because some of the internal field is escaping out into the void region. In order to build up the response again, conductivities are required near the surface. Figure 2 shows a model which gives a good fit to the observed amplification on the front side and which also agrees well with the backside

Fig. 2 Amplitude of the transfer function of an 8 layer model, calculated by including the void region behind the moon.

response⁷. There is a remarkable similarity between the conductivity values in the top 200 km of the Moon and those in the Earth's crust⁸. The temperature and pressure conditions in these regions of the Moon are probably quite similar to terrestrial crustal conditions, but in the Earth's crust the conductivity is probably associated with the presence of free water in the rocks. This possibility seems most unlikely for the Moon. A water-saturated lunar model, in fact, does not give a good fit to the electromagnetic response data, as it does not provide the increase conductivity-depth relationship that is needed because of the decrease of porosity with pressure. If free water is not present, then a semiconduction type of mechanism is required in order to explain the degree of conductivity observed at low temperatures.

In order to examine this more closely, various models of lunar temperature were assumed, and the electromagnetic response data were inverted to find the parameter of a semi-

Fig. 3 Model of the temperature distribution inside the moon. a, Solidus (anhydrous basalt); b, uranium concentration = $2.3 \times 10^{-8} \text{ g g}^{-1}$; c, $U = 1.1 \times 10^{-8} \text{ g g}^{-1}$.

conductor characterised by a conductivity prefactor, σ_0 , and activation energy, E_0 . The temperature models used are those of Toksöz *et al.*⁹ (Fig. 3). A very good fit to the data was obtained using this two-parameter model (Fig. 4). The parameters were not very sensitive to the temperature models (Table 1).

Table 1 Parameters of lunar semiconductor model

High temperature model	Low temperature model
$\sigma_0 \text{ mho m}^{-1}$ 2.1×10^{-3}	3.1×10^{-3}
$E_0 \text{ eV}$ 0.13	0.14

This low activation energy results from the fact that the electromagnetic data can accommodate only a moderate increase in conductivity at depths characterised by a sharp thermal gradient. Figure 5 shows a comparison of the conductivity values with laboratory measurements of terrestrial and lunar rocks. Low activation energy conduction has been observed in lunar rocks but the conductivity level is much lower than that inferred for the Moon¹⁰. These experiments were, however, plagued by thermal hysteresis. This was subsequently attributed to the experimental procedure¹¹. We are not yet able to draw definite conclusions on the lunar composition.

Fig. 4 Amplitude of the transfer function of a semiconductor lunar model which satisfies the high temperature curve in Fig. 3. The model values, x, agree with the data, Δ , except at 0.04 Hz

There is very little resolution in the present electromagnetic data for the electrical properties at depths greater than 700 km, and, therefore, another conduction mechanism cannot be identified. The shallower conductivity parameters were so insensitive to the temperature model variations, that temperature inferences could not be made from these results.

The model results were calculated by assuming the lunar surface magnetometer to be at the subsolar point, and the source field to propagate parallel to the downstream cylindrical cavity. The magnetic amplification depends, however, on detailed considerations of the location of the sensor relative to the subsolar point, and on the orientation of the magnetic field of the solar wind. Moreover, the data are sensitive to certain parameters of the solar wind. The results shown in Table 1 and Fig. 5 were computed using a solar wind velocity of 300 km s^{-1} . If 400 km s^{-1} is used, the conductivity parameters increase by 50% in σ_0 , and by 25% in E_0 . In this case the conductivity value of $10^{-4} \Omega^{-1} \text{ m}^{-1}$ is not reached until a depth of 150 km. The fluctuation of plasma pressure of the solar wind, which accompanies the magnetic fluctuations, is another parameter that can influence the results. An empirical correc-

tion for the interaction of the plasma with the remanent field at the Apollo 12 site has already been applied to the data³ and the resulting set of data agrees fairly well with that obtained at the Apollo 15 site¹². We have not included in our calculation the possible effect that these fluctuations might have on the diamagnetic signature usually observed in the downstream cylindrical cavity. We do not know to what extent these parameters can be reconstructed from the original observations.

These factors render our conclusion somewhat tentative but we believe, nevertheless, that the results suggest rather strongly that a conduction mechanism with a low activation energy plays an important role in determining the conductivity at shallow and moderate depths inside the Moon.

We are indebted to Colbert Reisz and Don Paul for advice and encouragement in this study. This work was supported by a NASA grant.

Tungus event was not caused by a black hole

JACKSON and Ryan¹ suggested that a black hole may have caused the Tunguska catastrophe in 1908, in which an explosion occurred in a remote part of Siberia. About 10^{23} erg (equivalent to 2 Mton of TNT) of energy was released. Several lines of evidence render the black hole hypothesis extremely unlikely.

The explosion blew down trees in open places within a radius of 30–40 km and seared them within a radius of 15–18 km. The exposed roots were directed towards the centre of the area². In ravines, partially protected trees remained standing, but many had had their tops broken.

These and other characteristics of the event indicated that the main part of the energy went into an explosion in the air. By contrast, a typical, solid nickel-iron meteorite first buries itself below the surface and then dissipates its energy in a subsurface explosion. The Barringer crater in Arizona, which is 200 m deep, and 1 km in diameter, was produced in this way. No significant excavation was caused by the Tunguska explosion.

It has been suggested that the event was caused by the impact of a small cometary nucleus, consisting of a mass of frozen gases mixed in with nickel-iron and silicate particles^{3–5}. The whole body would then have had a low degree of cohesion, so that it would have fragmented in the air and dissipated most of its kinetic energy before it reached the surface.

The air blast could also have resulted from the impact of a small black hole with a diameter of the order of angstroms and an asteroidal mass. The black hole would, however, have passed through the Earth in 10–15 min and caused a similar explosion at the point of exit, which would have occurred in the North Atlantic between 30°–40° W and 40°–50° N (ref. 1).

Microbarographs in the London and Cambridge areas recorded infrasound from the explosion⁶. The waves arrived at the centroid of the stations—51°30'N, 0°2'W—at approximately 0515 UT, on June 30, 1908. The impact itself occurred at 60°55'N, 101°57'E at approximately at 0017 UT (ref. 2). The approximate great circle distance from the point of impact to the centroid of the stations is 5,720 km, so the average speed of the waves was about 320 m s⁻¹, which is about the usual value for this type of wave.

It is clear that the recorded waves were travelling from Siberia, and not from the North Atlantic, because the microbarograph at Cambridge recorded the wave 10 min or so before the time that it was recorded at Petersfield. Infrasound waves from the site of the suggested exit explosion should however, have arrived in the London area between about 0215 UT and 0330 UT—about three hours before the arrival of the Siberian wave—assuming that any waves from either source travelled with the same velocity. We have examined copies of the English microbarograph records, but have been unable to find any sign of waves from the suggested exit explosion.

In the London area, the maximum recorded amplitude

⁴ Reisz, A. C., Paul, D. L., and Madden, T. R., *The Moon*, **4**, 134 (1972).

of the Siberian waves was about 150 μ bar. It is possible to resolve amplitudes which are as low as 20–30 μ bar, so that any waves not observed must have had amplitudes which were less than about 20% of those of the Siberian waves. The suggested exit site is, however, closer to London than is the Tunguska region, so the recorded amplitudes of exit waves at London should have been greater, than those of the waves from Siberia in the absence of unusual propagation effects. We have considered whether strong zonal winds to the west could have caused ducting effects which reduced the amplitude of the eastward travelling exit wave to below 20–30 μ bar. Ducting between the mesosphere and the Earth's surface reduces greatly the amplitudes of waves with periods shorter than a few tens of seconds when they are travelling upwind, but it reduces the amplitudes of waves with periods of 1–2 min, such as those recorded from the explosion, by only a factor of two or three. If such ducting had been in effect, any waves from the exit explosion should still have had amplitudes of about 100 μ bar in the London area. In addition, the eastward travelling reverse wave from the explosion was observed on a Fuess barograph at the Potsdam Geophysical Observatory about 26 h after the direct waves². If the eastward wave from the entrance explosion could propagate against the zonal winds it seems unlikely that eastward waves from an exit explosion could not do so as well.

Other arguments against the black hole hypothesis have been given by Wick and Isaacs⁵. The spatial pattern of numerous small magnetic globules with high nickel content found in the Tunguska region indicates that the source of these extraterrestrial particles was the impact explosion. Eyewitness accounts noted a thick dust train along the path of the fireball immediately after its passage, which is consistent with the deposition of material in the atmosphere, rather than loss of air into a black hole. The first night after the fall was exceptionally bright everywhere in Europe and western Siberia. In the Caucasus it was possible to read a newspaper at midnight without artificial light. That implies deposition of extraterrestrial material in the upper atmosphere simultaneously with the impact. The wide area of atmospheric deposition is comparable to the dimensions of a cometary tail, and is not compatible with the idea of slow transport of dust vertically and horizontally from a ground level explosion. The deposition in the upper atmosphere of both fine cometary dust and icy material could give rise, at high latitudes and at that time of year, to a phenomenon like noctilucent clouds. That could account for the bright nights.

Fessenkov⁶ investigated the measurements of the transparency of the atmosphere made in California in 1908, and found that from approximately the middle of July to the second half of August 1908, a noticeable decrease in the coefficient of transparency occurred. Fessenkov concluded that it was caused by the dissipation in the atmosphere of material from the Tunguska object. He estimated the total mass of dissipated material to be several million tons.

All the evidence favours the idea that the impact which caused the Tunguska catastrophe involved a body with characteristics like a cometary nucleus, rather than a black hole.

We thank the Director-General of the Meteorological Office for supplying copies of the microbarograph records and Dr J. M. Young of the National Oceanographic and Atmospheric Administration Geoacoustics Group at Boulder for discussion. This work was supported by the National Science Foundation.

The formation of the Earth

THREE recent hypotheses for the origin of the inner planets are based on chemical data obtained from meteorites or from solar observation^{1–5}. The chondritic earth model of Ringwood¹ or the cold accretion model (see summary in ref. 2) require partial melting of meteorite material and segregation of metal and sulphide to form a core, but the fractionation must have been a rapid, disequilibrium process to leave 2,000 p.p.m. Ni in the silicate mantle. The heterogeneous accretion model^{3,4} overcomes the problem of high Ni in the mantle by having accretion of the metal core first, followed by silicate mantle and finally by volatile-bearing material which formed the crust, no two fractions having been in equilibrium. Lewis⁵ maintains that condensation from a homogeneous nebula under differing physical conditions can account for the density variation between the inner planets without invoking the metal-silicate fractionation suggested by Urey⁶. Compared to the above hypotheses based on meteorite composition, the following approach is more direct as it is based on a reliable estimate of modern upper mantle composition.

The best estimate of undepleted upper mantle composition obtained from a study of some 200 spinel-lherzolite xenoliths in basalt, is as follows: SiO₂ 45.0, TiO₂ 0.09, Al₂O₃ 3.5, Cr₂O₃ 0.41, total Fe as FeO 8.0, MnO 0.11, NiO 0.25, MgO 39.0, CaO 3.25, Na₂O 0.28, K₂O 0.035; sum 99.92 (weight). (R. H., A. L. Chambers, D. K. Paul, and P. G. Harris, unpublished). This composition is close to that of three undepleted garnet-lherzolite xenoliths from the Bultfontein kimberlite pipe, but it has much lower TiO₂, Na₂O and K₂O contents than Ringwood's pyrolite¹.

In meteorites, Ni is always concentrated in the metal relative to the silicate. For example, the metal of pallasites has about 12% Ni (weight), but coexisting olivine has only some 20 p.p.m.⁷. If an Fe–Ni metal fraction had been segregated from silicate mantle to form or to enlarge the core, then Ni should have been almost quantitatively removed from the upper mantle. The Ni:Fe ratio of modern upper mantle, about 0.03, is much lower than that in meteorites but higher than that of the silicate of meteorites. One possibility put forward here is that Ni was almost totally removed from the mantle during early segregation of metal and sulphide into the core, then partially replenished by the addition of further meteorite material. If this assumption is made, the composition of pre-replenishment, Ni-free upper mantle can be calculated by subtracting a suitable amount of Ni carrier from modern upper mantle.

The most Ni-rich carrier, ataxitic iron meteorite, would require about 0.15 lunar mass to be mixed into the Ni-free upper mantle and oxidised. In addition to providing the 2,000 p.p.m. Ni, about 1% FeO (weight) would also have been introduced. At the other extreme, the maximum mass of material capable of providing the necessary amount of Ni would be just under three lunar masses of type 1 carbonaceous chondrite (C1). C1 fragments have been identified in a variety of meteorite types^{8,9}. In addition, C1 material has probably been incorporated into lunar regolith^{10,11}, and so seems a better candidate as Ni carrier than the rare ataxites. Although other types of chondrite are also potential Ni carriers, some C1 is necessary to provide the earth's volatiles and so the model presented here will consider C1 only.

§ † minus ‡

|| §, recalculated to 10,000 Si atoms – primitive Ni-free (and Na-free) upper mantle

To allow comparison between the upper mantle and meteorite groups, the method used for calculating the composition of hypothetical, Ni-free upper mantle is that of Larimer and Anders¹². In Table 1 the lithophile element contents of 'pyrolite'¹ and upper mantle as given above are expressed in atoms per 10,000 Si atoms. By subtracting 20% C1 from the modern upper mantle composition and recalculating to 10,000 Si atoms, primitive, Ni-free upper mantle composition is obtained. This has a 100 FeO:(FeO + MgO) molecular ratio of 5. In Table 2, the data of Table 1 are expressed relative to carbonaceous chondrite composition; ordinary and enstatite (E) chondrite compositions are also included.

Table 2 Lithophile element fractionation relative to carbonaceous chondrites

	*	†	‡	§		¶

† Modern upper mantle from composition given in text

‡ 'Pyrolite'¹

§ Carbonaceous chondrite

|| Ordinary chondrite¹²¶ Enstatite chondrite¹²

From Table 2 it is evident that fractionation of the lithophile elements has been different on Earth from that in meteorites. The sequence carbonaceous to ordinary to E chondrites has fairly regular depletion in all five elements, whereas in the upper mantle (column †) Al, Mg and Ca are enriched relative to carbonaceous chondrites, but Ti and Cr are depleted. 'Pyrolite'¹ shows the depletion in Cr, but not in Ti; this is probably due to a failing in Ringwood's model. The recalculated, Ni-free upper mantle composition shows the same trends as modern upper mantle, but accentuated by the subtraction of unfractionated material. Lack of coherence within the lithophile element group requires a mechanism different from any responsible for fractionation between the different chondrite groups, as does enrichment in Mg over Al and Ca. Gain by the Earth of the Mg, Ca, Al-rich fraction preferentially lost by ordinary and E chondrites¹² would have resulted in an impoverishment in Mg over Al and Ca in the upper mantle. These two problems are dealt with separately below.

Depletion of the upper mantle in Ti and Cr is best explained by their partial removal into the core as sulphides. In the highly reduced E chondrites, virtually all Cr occurs as the sulphide daubréelite¹³, and 75% of the Ti is present in troilite¹⁴. The figures in Table 2, column*, indicate that, in the upper mantle, conditions were less strongly reducing than those which obtained during the formation of the E chondrites, for, in the

former, a much higher proportion of the Ti and Cr remained as oxides. This is borne out by the presence of Fe in the upper mantle, there being virtually no oxidised Fe in E chondrites. Reducing conditions on Earth probably were not strong enough for reduction of significant SiO₂ to the metal, which occurred to limited extent in E chondrites. It is therefore unlikely that the light element in the Earth's core is Si. Removal of over half the Ti and Cr from the upper mantle probably took place during the early differentiation which also removed the Ni. The depletion in Ti and Cr and enrichment in Al, Mg and Ca cannot be accounted for by heterogeneous accretion.

Mg enrichment over Al and Ca could be the result of the Earth having gained pure forsterite (Mg₂SiO₄). I think, however, that the following two possibilities are more probable. Each necessitates SiO₂ loss from the upper mantle. The first and perhaps simpler explanation is that the mantle differentiated into upper and lower portions, with preferential enrichment of the latter in FeO and SiO₂ (refs 2, 15). This would be acceptable to geophysicists, whose models for lower mantle composition range from pyroxenite to harzburgite with molecular 100 FeO:(FeO + MgO) ratios from 36 to 20 (ref. 2). But this mechanism requires greater stability in the lower mantle of Ca and Al relative to Mg, a property which seems difficult to explain. The second alternative is that loss of almost three lunar masses of SiO₂ by evaporation from the upper mantle could have produced the observed Mg, Al and Ca enrichment, if primitive mantle had ordinary chondritic Mg/Si, Al/Si and Ca/Si ratios. The 35% SiO₂ loss necessary would have been accompanied by total depletion in alkalis and volatiles, but the addition of 20% C1 Ni carrier would have replenished the upper mantle in these; if the Na content of C1 of Schmitt *et al.*¹⁶ is used, the 0.28% Na₂O in the upper mantle is exactly accounted for. Abundances of other trace elements and alkalis in the upper mantle are not sufficiently well known for rigorous testing of this hypothesis. This second alternative is attractive in that an early period of surface heating might have radically altered the pattern of convection in the earth to ultimately bring about the distinction between upper and lower mantle. The second alternative could also apply to a homogeneous mantle, but in this case over ten lunar masses of SiO₂ would have had to have been lost.

The chemical composition of the upper mantle is incompatible with a single model based on heterogeneous accretion or cold accretion. Geophysical evidence for lower mantle composition² combined with the upper mantle composition given above suggest that the bulk mantle has a 100 FeO:(FeO + MgO) molecular ratio of about 20, in the range of the ordinary chondrites. Ordinary chondrite parent is also required to explain the enrichment in the upper mantle of Mg over Al and Ca. Although Anders¹⁷ maintains that the five components of meteorites (lithophile elements, metal, silicate, sulphide and volatiles) should each be considered independently in modelling planetary composition, the evidence put forward here argues that this might not be necessary.

My preferred model for the formation of the Earth is as follows: accretion began either as a metal-rich core followed by ordinary chondrite material, or as iron-rich ordinary chondrite-like material alone. Partial melting resulted in loss of siderophile and chalcophile elements from the silicate mantle to the core. Surface heating by a superluminous sun drove off volatiles, alkalis and about 35% of the SiO₂ from the upper part of the primitive mantle. Addition of C1 material during protracted cooling of the earth added Ni, alkalis, and, finally, volatiles. That accretion took place on an extended time scale is evidenced by meteorites, some of which have grains irradiated by solar flares in their interiors; such irradiation must have occurred after the dissipation of the bulk of the nebular gas¹⁸.

Along the midplane, pressure in the solar nebula increased towards the centre¹⁹. The series carbonaceous to ordinary to E chondrites represents material accreted under increasing

nebular gas pressure²⁰⁻²². Because the oxidation state of the Earth is close to that of ordinary chondrites, the more highly reduced E chondrites probably originated within the orbit of the Earth. This possibility is currently being considered.

I thank R. K. O'Nions for criticism, and A. L. Graham and K. K. Turekian for discussions.

Inner floor of the Rift Valley: first submersible study

THE Rift Valley of the Mid-Atlantic Ridge¹, within which lies a segment of the accreting plate boundary between Africa and North America, is well defined between 36° 40' N and 36° 55' N. It is about 30 km wide and 1.5 km deep in that area (Fig. 1). This small portion of the rift, WSW of the Azores, was chosen as the primary target of the French-American Mid-Oceanic Undersea Survey (FAMOUS) programme, and many surface ship studies have been conducted already. We report here preliminary results of seven dives into the deepest part of the Rift Valley that were made by the bathyscaphe *Archimède* during the summer of 1973.

Fig. 1 Topographic cross section of the Rift Valley near 36° 50' N, based on surface-ship data², showing the setting of the Inner Floor in the area of the *Archimède* dives (Fig. 2).

Needham and Francheteau² showed that, in the area visited by *Archimède*, steep, inward facing slopes of the deepest outward tilting blocks of the Rift Valley walls bound an uneven, regionally flattish Inner Floor. The central part of this is occupied by a ridge, 200 m high and asymmetric along at least part of its length. The ridge, or Central High², which we have named Mont de Vénus, is about 4 km long and 1 km wide. Two marginal topographic highs, or platforms, mapped during the course of a detailed narrow beam echo-sounding survey made by the French naval vessel *d'Entrecasteaux*, lie along the bottom of the bordering scarps of the Inner Floor (cv. Schrumph, cc. Caillaud, and V. Renard, personal communication). The marginal highs extend further south than Mont de Vénus and may be more rectilinear in gross shape.

The width between the major bordering scarps of the Inner Floor is 3.3 km. Assuming a mean opening rate of about 2.2 cm yr⁻¹, the Inner Floor may be entirely younger than 1.5 × 10⁶ yr, an inference supported by the occurrence here of very fresh lavas². All seven dives of *Archimède* took place within the Inner Floor, and all were concentrated in an area of less than 5 km² near 36° 50' N (Fig. 2).

The major purpose of the dives was to show that useful, detailed geological mapping of very rough deep sea terrain, such as the Inner Floor, can be undertaken from a manned submersible. It was further hoped that new evidence could be gathered, which would help to answer two important questions. First, is the surface expression of the boundary between the two diverging lithospheric plates confined to one of the highs or deeps within the Inner Floor, or is the locus of emplacement of new crust spread over a wider zone? And second, is the structural pattern of the Inner Floor steady state or transient? With these problems in mind, an effort was made to search for evidence of tectonic activity and to establish specific associations between microtopography and lava morphologies. A close, precisely controlled look was taken at a considerable part of Mont de Vénus, and at the eastern deep and adjacent marginal high (Fig. 2).

About 9 km was covered by the dives, in visual contact with the ocean floor. The position of the *Archimède* was known within 10-200 m, depending on her distance from the nearest of the acoustic transponders that were moored to the bottom and used for navigation. The transponder network for positioning *Archimède* was tied, with an accuracy of about 50 m, to the networks used by the *d'Entrecasteaux* in the making of the detailed surface-ship map that was used as a base for the dives. The scale of features that could be resolved (0-20 m) is clearly beyond the reach of surface-ship, or even deep-towed, instrumentation. A downward looking sonar and a pressure gauge were used to measure the altitude and relative depth of *Archimède* respectively. These were recorded every 10 s on digital printouts, and the precision was about 1 m. Useful complementary information was provided by a panoramic sonar device with a maximum range of 1,400 m. A dual system of still and television cameras (which kept film and videotape recordings) gave good images of the sea floor, whether it was flattish or very steep; the usual distance of observation was 3-5 m, and the maximum distance about 10-15 m. A telemanipulated grab was used for sampling and four pillow fragments, together with small quantities of sediment, were collected during the course of the dives.

Mont de Vénus is largely covered by recent lava flows. It is a lenticular structure with apparent dextral offsets. Above a water depth of 2,560 m its summit is less than about 500 m wide and deepens progressively northwards (Fig. 2). The surface of the summit is characterised by large (approximately 1 m) globular (dome like) lava forms (Fig. 3a) partially immersed in pale, carbonate-rich sediment. The globular structures may represent the surface ex-

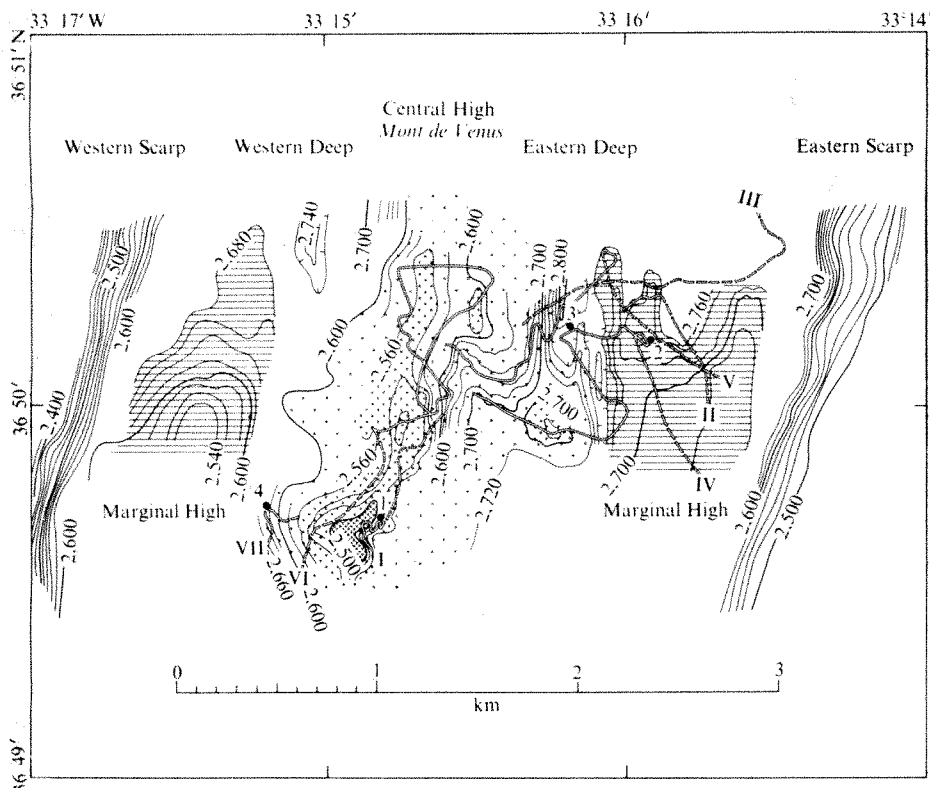

Fig. 2 Map of the Inner Floor of the Rift Valley of the Mid-Atlantic Ridge (Fig. 1), showing tracks of Archimède and positions of rock samples taken from Archimède. Roman numerals, sequences of dives 1-7; ●, rock samples. Different ornamentation for Central High and marginal highs helps to distinguish these features. The map is based on Archimède data along tracks and other contours are sketched from the d'Entrecasteaux map. Depths shown are from pressure gauge and downward looking sonar measurements made from Archimède, or are normalised to this base; corrected depths recorded by precision echo-sounders from surface ships are approximately 30 m smaller. The average cruising speed of the bathyscaphe was less than 1 knot when in visual contact with seafloor. The map is tied to Europe 50 coordinates. Depths are in metres. Track of Archimède: continuous double lines, visual contact with ocean floor; broken double lines, sonar contact with ocean floor.

pression of the top of a gently dipping, coherent lava flow unit (J. G. Moore, personal communication). The sediment may be thin, but it occupies up to 80% of the fields of view from the bathyscaphe. No large open fissures, nor any definite indications of small fissures, were seen. On the crest of the summit, relatively gentle slopes are distributed over a width of 50 m, and the organisation of lava flows shows that the crest coincides with the dividing line between eastern and western sets of flows, both directed downslope. In addition, mapping from Archimède demonstrated that the steep south-eastern slopes of the summit of Mont de Vénus are lobate in character. The wavelength of the lobes was typically 50-100 m.

The topography on the eastern side of Mont de Vénus down to the bordering deep is of a staircase type, with precipitous, north-south scarps, free of sediment, separating relatively flattish areas where the sediment cover is sporadic. One of the scarps is about 100 m high and has a slope of about 80° (Fig. 2). There is also a prominent east-west trending slope near 36° 50'N (Fig. 2). Cylindrical lava forms several metres long, which we call bolsters (Fig. 3b), are present on all of the traversed scarps. The bolsters are commonly associated with shorter, phallus shaped forms which we call phalli (Fig. 3b), and with lava forms resembling entrails which we call tripe (Fig. 3c). Some of the lavas associated with the scarps suggest regular stacking. Tali of lava fragments (Fig. 3d) occur typically at the feet of the scarps; and domed or globular, and commonly striated forms, similar to those seen on the summit, are a feature of the flatter areas between scarps. Collapsed or broken pillows (Fig. 3e) and bolsters occur on the scarps and on the flatter areas.

The short section of slope crossed by the bathyscaphe on the western side of Mont de Vénus has a relatively uniform gradient and is less steep than scarps crossed on the eastern side, but it is similarly typified by bolsters which were directed downslope. Some of these reach lengths of as much as 7 m, and many collapsed forms are present. No fields of angular boulders were seen, and sediment cover of up to 15-20% was observed.

The scarps bordering the deep to the east of Mont de

Vénus follow north-south directions rather than the dominant NE-SW trend of the summit. Isolated boulders lie on a blanket of sediment on the flattish floor of the deep, and some of them are obviously detached from adjacent flow fronts. The floor of the deep is represented, at least locally, by an extremely narrow (15-20 m) corridor (Fig. 2).

East of the deep, a series of ridges, with a relief of about 50 m or more, represent northward deepening fingers of the marginal high that lies between Mont de Vénus and the major eastern scarp of the Inner Floor. The topographic grain of the eastern region seems to be more linear than that near the summit of Mont de Vénus. Slopes of the eastern ridges, however, are similarly covered by coherent lavas, including elongated forms which are directed downslope; the measured flow directions are predominantly north-west to west on the westward facing slopes, and mainly east on the eastward facing slopes. Sediment cover, locally prominent in the flatter areas, is sparse on the slopes which represent the inner edge of the eastern marginal high. There is appealing local evidence, along these slopes, of a north-south, possibly normal, fault with a 2-3 m throw (Fig. 3d).

The four pillow fragments collected by Archimède come from very well known positions (Fig. 2) and, although not sampled from outcrops, they are evidently derived from adjacent flows. The rocks vary in size from 20-40 cm in diameter, and weight 15-47 kg. They are well jointed, have glassy selvages in various states of preservation and are similar, in mineralogy and chemistry, to other rocks from the Mid-Atlantic Rift Valley³.

Samples 1 and 4 from Mont de Vénus are olivine tholeiites with olivine crystals set in a matrix containing olivine, plagioclase and traces of spinel. Sample 2, an aphanitic pyroxene tholeiite from east of the eastern deep, is made up of equal amounts of plagioclase and clinopyroxene. Sample 3, a picritic basalt from the eastern depression itself, contains abundant, large olivine crystals set in a groundmass of plagioclase laths, olivine and a dark mesostasis; minor spinel is present both within the olivine, or as isolated crystals. The two Mont de Vénus tholeiites are more

Fig. 3 Different types of lava morphologies on the Inner Floor of the Rift Valley, mapped from the bathyscaphe. *a*, Globules, partially immersed in sediment; particularly characteristic of flat and gently dipping areas. Photograph taken on summit of Central High. *b*, Bolsters and shorter blunt ended forms (phalli); directed downslope; typically found on several steep and very steep slopes where sediment cover is absent or sporadic; note cracked glassy selvages and longitudinal striae. Photograph taken on western slope of eastern marginal high. *c*, Tripe, frequently associated with, or occurring on, other lava forms found on slopes. Photograph taken on western part of eastern marginal high. *d*, Talus of well jointed lava fragments at foot of steep, probably faulted scarp; in general, sediment-free talus is typical of feet of steep slopes including those covered by lava forms which are directed downslope. Photograph taken on western slope of eastern marginal high. *e*, Pillow, broken egg structure and frozen lava flow; similar isolated lava forms lie commonly on less steep parts of slopes and on flattish areas where sediment cover is relatively abundant. Photograph taken on western edge of eastern marginal high.

mafic, with higher MgO (10%), and lower TiO₂ (0.8–0.9%) and K₂O (0.15–0.2%) content than the tholeiite sampled further east (6.4% MgO; 1.6% TiO₂; and 0.4% K₂O). The most mafic of all four sediments is the picritic basalt (sample 3) which contains 22.6% MgO, 0.5% TiO₂ and 0.06% K₂O (P. Cambon, personal communication).

The four specimens show different degrees of surface weathering. Using the thickness of manganese⁴ and palagonite⁵ as indicators, and assuming a mean manganese accumulation rate of 3 μm per 10³ yr, suggests that all of the samples are younger than about 10⁵ yr. The youngest rocks are the two samples from Mont de Vénus; these are younger than 10⁴ yr. Sample 3 from the eastern depression is at least twice as old and sample 2 at least three times as old. The data thus suggest the possibility that the age of the Inner Floor increases eastwards from Mont de Vénus.

The results of the dives, taken together, lead to some general conclusions. Steep, and very steep (80–90°), major slopes of the Inner Floor near 36° 50'N are associated with bolsters which are in a downslope direction and other elongated and blunt ended lava forms. Lava talus is clearly associated with the feet of the scarps. Globule (dome) shaped, and commonly striated pillows lie more

or less buried in sediments on flattish areas between scarps. Incipient break-up of many of the intact lava forms is indicated by jointing and cracking.

The lobate structures and the distribution pattern of lava forms on scarps and slope surfaces indicate that Mont de Vénus is a constructional volcanic feature, with the corollary that its major scarps are the fronts of one or more flow units. It is, nevertheless, possible that flows which are directed downslope mask evidence of vertical movements that have contributed to the process which formed the scarp. Such an interpretation would be consistent with the steepness of the scarps and with the partially demonstrated bilateral asymmetry of Mont de Vénus. The apparently straighter trend of structures east of the eastern deep which flanks Mont de Vénus, and the local evidence of faulting along the inward facing slopes of the eastern deep, point rather more persuasively to some tectonic influence between the faulted scarps that border the Inner Floor. Indeed, the mapped part of the eastern deep near 36° 50'N may be a tensional fissure and the volcanic activity reflected by the downslope flows east of the eastern deep may be associated with dilation and small scale vertical movements.

The observation that the two rocks sampled from Mont de Vénus are younger than those sampled further east suggests, in a tentative way, that Mont de Vénus is the youngest part of the Inner Floor. The dominant, and approximately central position of Mont de Vénus within the Inner Floor adds some weight to this inference, as does the limited evidence that the relief of the marginal highs has been more subject to modification by vertical movements than that of Mont de Vénus itself. It seems, therefore, quite possible, although young lavas are found over a considerable part of the width of the Inner Floor, that Mont de Vénus represents the most recent surface expression of new crust along the plate boundary.

We acknowledge the contributions of the Archimède pilots and engineers; the assistance of officers, technicians and crew on board the French Navy ship Marcel Le Bihan; and the support of C. Riffaud. We also thank V. Renard, J. Phillips, J. Moore and other members of the US Scientific group of the FAMOUS programme, and M. Mattauer and P. Tapponier also helped with discussions.

Negative magnetic anomaly associated with Mount Kenya

MOUNT Kenya is a large central volcano just south of the equator in central Kenya. It rises to a height of 5,199 m above sea level. The base of the volcano covers an area of approximately 7,000 sq km, and is roughly circular in plan with an average diameter of 105 km. A detailed geological study¹ indicated that some 1,500 m of the upper part of the mountain has been removed by erosion since the volcano was formed in the Plio-Pleistocene.

The highest peaks of the mountain are formed from the eroded central plug which is about 2.2 km in diameter. There are a number of small glaciers in the peak area, the

intensity, associated with the peak area and displayed by all the observations.

All field measurements were made with a proton precession magnetometer and have been reduced to a common epoch time of 1430 UT on March 16, 1974, by using the continuous variometer records from the Nairobi geomagnetic observatory. The correlations for epoch were small and less than 60 γ in all cases ($1\gamma \equiv 10^{-9}T$). In addition to the field measurements on the volcanic plug, measurements were taken at six sites along the main approach track from the township of Naro Moru which is situated 32 km due west of the peak of Mount Kenya. (Fig. 1 and Table 1).

Corrected values of total intensity, F , have been plotted as a function of the distance of each measuring site from

Fig. 1 Sketch map of the positions of the measuring sites along the track from Naro Moru to Batian. Contours are in feet. Shaded area, volcanic plug; \odot , Lewis Glacier; Δ , Batian; \times , Top Hut.

largest of which, the Lewis glacier, is being studied in detail by one of us (S.H.). As part of this study, with a view to determining the thickness of the ice and the shape of the underlying topography, close-spaced measurements were taken of the total intensity of the geomagnetic field along two profiles across the Lewis glacier at altitudes near 4,785 m. The glaciological interpretation of these observations will be reported in detail elsewhere. We here draw attention to a large negative anomaly in the total field

Batian, the highest peak of Mount Kenya (Fig. 2). The expected regional field value for the area (34,440 γ) obtained from a recent magnetic survey of the whole of Kenya (N.J.S.) is also shown (Fig. 2). A shallow negative anomaly of up to -400 γ exists over the whole traverse (all of which is underlain by volcanics from Mount Kenya), and the anomaly is sharply accentuated to greater than -1,300 γ on the volcanic plug. A somewhat similar negative anomaly of even larger amplitude has been reported on the volcano

Table 1 Data from the measurement sites

Map No.	Measuring site	Latitude	Longitude	Altitude (m)	Distance from Batian (km)	Total field F , corrected to common epoch (γ)

Kilimanjaro in northern Tanzania², and in this case also the anomaly increases sharply near the peak (Kibo) of the mountain.

The plug of Mount Kenya is composed of a central core of nepheline syenite with outer partial sheaths of fine grained phonolite which in places is penetrated and locally altered by the syenite. Baker¹ considers that the main inner syenite body is younger than the adjacent phonolite but it is not clear whether all the syenite was emplaced in a single phase of volcanic activity. Evernden and Curtis³ have given isotopic ages of 2.64 Myr for a specimen of nepheline syenite taken from the plug and of 3.1 Myr for phonolite from the main eruptive phase collected near Embu, 40 km south-east of the peaks. The intense local negative field anomaly associated with the plug suggests that the rock of which it is composed possesses strong 'normal' remanent magnetisation, that is, it was emplaced at a time when the Earth's magnetic field was in the same direction as at present. Furthermore, an oriented specimen of phonolite collected at the edge of the Lewis glacier, near Top Hut, was strongly magnetised in a 'normal' sense. The present magnetic field measurements and the isotopic date of 2.64 Myr for the syenite suggest that the last eruptive phase through the main vent of Mount Kenya occurred during the Gauss normal epoch. The high degree of erosion of the peak area certainly precludes eruption during the present Brunhes epoch. On the other hand, for Kilimanjaro, the relatively slight degree of erosion of the Kibo crater, and the large negative magnetic anomaly², point to a much younger main eruptive phase within the Brunhes normal epoch, and this is confirmed by the isotopic ages in the range 0.365–0.514 Myr for basalts from Kilimanjaro³.

The sub-Palaeozoic basement in central Ireland

THERE is no direct evidence to indicate the nature of the sub-Palaeozoic basement beneath central Ireland. The recognition of gneissic xenoliths in Viséan volcanics in this region is therefore significant. They have been located at Croghan Hill in County Offaly (National grid ref. N4833; Fig. 1), Clare Castle (N2447), and the Dungolman River (N1851) in County Westmeath.

At the first locality one specimen, 30 cm³ in volume, was found in agglomerates cropping out to the west of Croghan village, and a second specimen of 1,600 cm³ in basalt a little further south. From agglomerates near Clare Castle 17 specimens were obtained, ranging from 10–200 cm³. The agglomerates from this latter locality occur as loose

Fig. 1 Localities referred to in the text and areas of Dalradian or older rocks (horizontal ruling), Lower Palaeozoic rocks (shading), Upper Palaeozoic rocks (blank) and Mesozoic and Tertiary rocks (diagonal ruling).

boulders, often of great size, and they are certainly of local origin. They predominate in the boulder train and their lithic content, of Upper Palaeozoic age, closely matches that from beneath the area, which is known from boreholes (K. Cullen, personal communication). Similar agglomerates outcrop 11 km to the north-west in the bed of the Dungolman River. Material dredged from the bed of the river includes basalt fragments containing a further 10 xenoliths ranging from 10–30 cm³.

The Clare Castle gneisses are coarse grained and weakly banded, and contain the mineral assemblage: garnet–sillimanite–potash feldspar–plagioclase–quartz–rutile. Euhedral garnet, up to 2 mm across, has a composition close to the pyrope–almandine join at about 56% almandine. Sillimanite prisms up to 10 mm long define a strong lineation. Both feldspars are quite fresh. The plagioclase composition is An_{45–50}, and it is unzoned; the potash feldspar is a string perthite. Modes vary within the range: garnet 20–30%, sillimanite 5–20%, plagioclase 25–30%, potash feldspar 10–20% and quartz 10–40%. Other phases occur only in small amounts. Books of graphite up to 2 mm long occur in most specimens and there are traces of phlogopite in a

few cases. The assemblage belongs to a high amphibolite or granulite facies.

The gneiss from the agglomerate at Croghan is very similar, though it lacks potash feldspar. That from the basalt is very altered; only coarse sillimanite and quartz remain in a matrix of secondary chlorite, fibrous amphibole and altered glass. Abundant pseudomorphs after garnet can be seen readily, however, and Watts¹ has observed garnet in xenoliths from the area.

The gneisses from the Dungolman River are undoubtedly of granulite grade: they contain the critical assemblage hypersthene-garnet. They are rich in basic plagioclase (about An₆₀), hypersthene, garnet and quartz, and are medium grained and weakly banded. There is some alteration to anthophyllite, chlorite and carbonates.

Other lithic fragments are abundant in the agglomerates. Many compare with phyllites and slates of currently accepted Ordovician age which are exposed in the surrounding Lower Palaeozoic massifs. These rocks are of an extremely low metamorphic grade. That is in strong contrast to the gneisses which are therefore likely to be Dalradian or older. Indeed, the only rocks of similar type in Ireland are pre-Dalradian. The Dalradian everywhere differs in lithology²⁻⁴ and is generally of much lower grade, though it reaches middle amphibolite facies in places. The older Deer Park Schists⁴ are also unlike the xenoliths. Gneissic rocks from north-western Mayo⁵ and the Rosslare Complex^{6,7}, which may be Lewisian, are mica bearing and poor in garnet, and of a distinctly lower grade. The only comparable rocks are those from the Precambrian of the Ox Mountains, which Lemon⁸ has tentatively referred to the Moinian. These differ in that they contain kyanite.

The gneisses are clearly much older than the Lower Palaeozoic sediments. It is most unlikely that the gneiss has been derived indirectly, from the Old Red Sandstone (ORS) for example. None of the 29 xenoliths has adhering sediment, and gneissic clasts do not occur in the ORS exposed in nearby areas, or in ORS blocks within the agglomerates themselves. The gneiss must have been derived from the sub-Palaeozoic basement.

That is of interest in view of recently proposed plate tectonic models of Precambrian and Lower Palaeozoic history. Most of those require oceanic crust to lie beneath the Southern Uplands and its structural continuation into central Ireland⁹⁻¹³. Though some are not clear on the point, others clearly show this to be present even after the final Caledonian deformation. Powell¹⁴ has pointed out that the geophysical evidence conflicts with that idea, and proposed that there is a sialic basement "of Lewisian-type rocks" beneath the Southern Uplands. Jeans¹⁵ has accepted this, and his model shows oceanic crust lying, virtually pinched out, beneath the Midland Valley. The evidence presented here strongly support the latter hypotheses.

It is improbable that the gneiss was derived from a detached slice of sialic crust thrust over the oceanic basement. The localities discussed here are separated by 35 km, and the furthest is 70 km from Strokestown, the nearest point on the northern subduction zone proposed by Dewey^{6,7}. It is far more likely that beneath this area there is a true basement of high grade metamorphic rocks. It seems probable that this basement extends beneath the Down-Longford Massif and into the Southern Uplands.

I would like to thank Mr K. Cullen of Irish Base Metals Ltd, who brought my attention to the Clare agglomerates, and IBM who supplied drilling logs from the area. I also thank Drs J. R. Andrews and P. S. Kennan for discussion and criticism.

Reversals of the Earth's magnetic field and climatic changes

It has been suggested that evolution may be influenced by reversals of the Earth's magnetic field¹⁻³. It was observed that there were correlations between discontinuities in microfossil assemblages (or evolutionary discontinuities) and reversals of the Earth's magnetic field in deep sea sediment cores⁴⁻⁶. This observation was put on a firm base when Hays⁷ showed statistically that reversals directly or indirectly exert a selective influence on radiolaria. The explanation offered by Uffen^{1,2} and Simpson³ for the connection between evolution and reversals was that during reversals of the Earth's magnetic field, the intensity of the field would be reduced to a very low value, allowing organisms at the surface of the Earth to be bombarded by increased cosmic radiation normally shielded by the field. This increased radiation should then cause an enhanced mutation rate and hence produce an evolutionary discontinuity. It was, however, shown later that the estimated increase in the mutation rate would be small and unlikely to cause evolutionary discontinuities⁸⁻¹⁰.

Two other ways have been suggested in which reversals of the Earth's magnetic field could influence evolution. One way is by the direct biological effect of a magnetic field on organisms; there is a short discussion of this by Crain¹¹. The second mechanism proposes that a reversal of the Earth's magnetic field could cause a change in the climate of the Earth and hence indirectly produce faunal extinctions¹⁰.

Here, we shall discuss the second proposed mechanism and speculate on a possible causal relationship between reversals and climate. Evidence has been previously presented (for example refs 12, 13) suggesting a connection between the Earth's magnetic field and climate. Wollin *et al.*¹² showed that the record of mean annual temperature (averaged over 10-yr periods) was inversely correlated with the magnetic field intensity at nearby magnetic observatories. They were, however, unable to suggest what the causal relationship between these two parameters was. King¹³ has discussed the possibility that the Earth's field controls in some unknown way the variations in pressure to be found at high latitudes in the troposphere. King has also suggested¹⁴ that solar ionising particles are responsible for some of the correlations to be seen between the yearly mean sunspot number and various meteorological phenomena.

Roberts and Olson¹⁵ have demonstrated a relationship between one climatic parameter and geomagnetic disturbances and have also offered an explanation for this relationship. They have

Fig. 1 Ionisation as a function of latitude. Curves are shown for four altitudes (measured in km).

shown¹⁵ that troughs at the 300 mbar level are influenced by geomagnetic disturbances. They found that, during the winter, troughs which moved into the Gulf of Alaska between 2 and 4 d after a geomagnetic storm underwent a greater degree of intensification than did troughs which appeared at the same place and during the same season but not within the 2–4-d time lapse after a geomagnetic storm. They suggest that this intensification may be caused by modification of the black body radiation from the relatively warm North Pacific as a result of increased cirrus cloud cover. It is thought by Roberts and Olson that increased ionisation at the tropopause level, caused by the ionising particles associated with the geomagnetic disturbances, could cause ion-induced nucleation and, hence, enhanced formation of clouds; the increased cirrus cloud cover at high latitudes during the winter results in a decrease in cooling rate which, in turn, leads to the increased vorticity.

A reversal of the Earth's magnetic field must be classified as a major geomagnetic disturbance. It is believed that the period of reduced field intensity during a reversal lasts between 1,000 and 10,000 yr^{16,17}. During the time of very low magnetic field intensity, the whole Earth would receive the present-day polar cosmic ray ionisation rate, all other factors being assumed to remain constant. We can estimate this rate by using the data of Saylor *et al.*¹⁸ for latitudinal variations in cosmic-ray ionisation rates as a function of altitude.

Table 1 gives ionisation rates at three different altitudes and at the equator and pole, taken from ref. 18. The top figure in each category gives the rate during a solar activity maximum, and the lower figure gives the rate during a solar activity minimum. Means

of the two values are given, and the polar/equatorial ratios of the means are shown in the last column.

Figure 1 shows the mean ionisation rate plotted as a function of latitude for four different altitudes. It can be seen that half or more of the Earth's area at these altitudes would have the ionisation rate increased by a factor of two or more during a reversal, if it is assumed that the polar ionisation rate is applicable to the whole Earth during a reversal. Using these curves and performing a simple numerical integration to determine average ionisation rates over the Earth's surface, it can be shown that the average ionisation increases by factors of 3.03 (for the lowest altitude curve), 2.87, 2.84 and 3.11 (for the highest altitude curve). If Roberts and Olson¹⁵ are correct in assuming that ionisation at such levels in the atmosphere is important for the production of cirrus clouds, then we should expect profound changes in the Earth's climate during a reversal, due to increased cloud cover at lower latitudes.

Table 1 Ionisation rate, (10^6 ion pairs $m^{-3} s^{-1}$) (measured at a pressure of 101.3 kN m^{-2})

Altitude (km)	Equator	Pole	Ratio
9.144	14.3 } 21.4 28.6 }	102.4 } 104.7 107.1 }	4.9
12.192	33.3 } 52.3 71.4 }	211.9 } 219.0 226.2 }	4.2
15.240	69.0 } 77.3 85.7 }	285.7 } 326.2 366.7 }	4.2

The specific mechanism which Roberts and Olson¹⁵ suggest as being responsible for the formation of cirrus, ion-induced nucleation, is highly speculative. Castleman¹⁹ presents evidence that ions can promote water vapour nucleation at supersaturation ratios considerably below that required for homogeneous nucleation; he suggests, for example, that at the summer mesopause (130 K, water concentration 10^9 cm^{-3}) sufficient supersaturation exists for this nucleation process to be operative. But Castleman does not state if this process would be significant lower in the atmosphere. Montefinale *et al.*²⁰, in a review of recent advances in the chemistry and properties of atmospheric nucleants, decline to discuss the role of ions because of the lack of information on the primary chemical nature of the ions and, hence, on their modes of action; they exclude ions from the population of active condensation nuclei on the basis of the high water supersaturations necessary for the ions to become active. On the other hand, Montefinale *et al.*²⁰, suggest that ions, because they electrostrict conspicuous amounts of water molecules, may be responsible for the vertical transport of water under the influence of the electric gradients in the atmosphere. This transport may, in itself, have a significant role in effecting weather changes in response to geomagnetic events.

Because of the general lack of knowledge about the physical and chemical properties of the upper atmosphere, the questions concerning the nature of the mechanism linking geomagnetic disturbances and weather will most probably remain unanswered for some time. But we submit that the relationship between geomagnetic disturbances and weather warrants further investigation not only because of the short term implications but also because such studies may lead to an explanation of climatic changes on the geological time scale.

Equatorial undercurrent and climate in the Galapagos Islands

PALYNOLOGICAL data from sediment cores taken from El Junco crater lake on San Cristobal Island led to the recognition of stratigraphical fluctuations resulting from the water budget in the crater¹. The results show that the crater was dry between at least 34,000 and 10,000 yr BP. Colinvaux¹ suggested that the Galapagos Islands had a dry climate during that period, because the intertropical convergence zone (ITCZ) remained north of the geographical equator. On the other hand, Newell² showed that the ITCZ probably existed south of the equator at about that time (20,000 yr BP).

I demonstrate here that another mechanism could explain this general dryness.

The climate in the Galapagos Islands is influenced by regional and local hydrographic conditions which regulate the annual course of the temperature in the superficial waters. The most prominent features of the thermal properties in the Eastern Tropical Pacific are the upwellings: those which occur along the coast of the South American mainland, and those which are connected to the divergence along the equator. I have already shown³ that the local upwelling west of Isabela is a fluctuating but permanent feature which influences the temperature distribution throughout the archipelago. The annual thermal regime in the superficial waters of the islands is balanced between the warm season, when warm waters are drifting from the north and solar heating takes place, and a

cold season, when upwelling reaches maximum development.

Year to year comparisons of meteorological data and surface sea temperature, taken at the Charles Darwin Research Station (Bahia Academia, Santa Cruz Island)^{4,5}, have revealed that interannual variations in the thermal regime are similar to those recorded further east in the coastal waters along the Peruvian^{6,7} and Ecuadorian coast (G. Houvenaghel, unpublished). There is also a good correlation between the annual rainfall values from some localities on Santa Cruz Island, and the annual mean sea temperature measured in the surface waters at Bahia Academia (Fig. 1). The climate may be characterised using the pluviothermic quotient of Emberger. Calvet⁸ gives a formula for the computation of a pluviothermic quotient from the annual rainfall, R , the mean air temperature of the hottest, T , and the coldest, t , month, and the evaporation:

$$Q = 1,000 R / 0.5 (T + t) (P_T - P_t)$$

where P_T and P_t are the water vapour pressure at temperatures T and t , respectively. Plotted against the mean annual sea temperature (Fig. 2), the computed values for Q also correlate well. Figure 2 shows that only a small decrease

Fig. 2 The relationship between the mean annual seawater temperature and the annual pluviothermic quotient, Q , at Bahia Academia: $r = 0.91$ ($r = 0.87$, $P = 0.01$).

Fig. 1 The relationship between the mean annual seawater temperature, taken at Bahia Academia (Santa Cruz), and the rainfall collected in the same year at selected stations on Santa Cruz Island: ●, Bahia Academia (altitude, 6 m); ▲, Divine (320 m); ○, Media Luna (620 m); solid diamonds (200 m). a, $r = 0.903$; b, $r = 0.995$; c, $r = 0.996$; d, $r = 0.996$. (••, $r = 0.875$, $P = 0.01$; (*), $r = 0.990$, $P = 0.1$).

in the mean annual sea temperature is required to provide an arid or desert climate in the highlands of Santa Cruz. El Junco crater is located at an altitude of 650 m (ref. 1) which is intermediate between the highest two recording stations on Santa Cruz, and so the climate conditions prevailing on San Cristobal Island, 100 km ESE of Santa Cruz, must be similar to those recorded here. The dry climate which according to Colinvaux¹ existed in the past, could well have developed if a superficial cooling of sea water by about 1°C occurred at that time. Cooling can be expected to follow only a slight increase in the rate and duration of the upwelling (such as occurred, for example, during 1967) and it could last throughout the entire dry epoch. According to Bjerknes's model of equatorial circulation⁹, increases in both rate and duration of upwelling depend on the oceanwide stress of trade winds on the equator. Cooling in the Galapagos Islands may thus occur if the intensity of the field of the SE trade winds is increased. This could have been the case in the past: Newell² reports that the temperature gradient in both hemispheres was higher at 20,000 yr BP, and that the intensity of the Hadley cell circulation increased as well.

A dry climate in the Galapagos Islands could thus result

from changes in the intensity of the southern trade wind rather than from the shifting and continuing existence of the ITCZ in the Northern Hemisphere.

Relative sizes of high and low spin states of atoms

STRUCTURAL studies with X rays^{1,2} of five and six-coordinated iron porphyrin complexes have shown that the distance from the iron atom to the nitrogen atoms of the porphyrin rings is less for low spin Fe(III) than for high spin Fe(III). As a result, it is often assumed that the Fe(III) atom is larger in its high spin state than in its low spin state. Similar size differences for the Fe(II) system form the basis of the Perutz model³ for the cooperativity of oxygen binding in haemoglobin. I discuss here the relative sizes of the high and low spin states of atoms in terms of the results of quantum mechanical calculations on isolated atoms. Contrary to earlier interpretations of structural studies, I have found that in the atoms I have studied the lowest lying high spin state of an atom in a given configuration is smaller than any state of lower spin.

Any theoretical discussion of the size of atoms must be concerned, in one way or another, with the radial density function $D(r_1)$ which is a measure of the probability of finding an electron at a distance r_1 from the nucleus. Unfortunately there is no unique definition of the size of an atom. In fact, many indices may be considered to be of atomic size. For example, the mean value of r_1 , denoted by $\langle r_1 \rangle$, is proportional to the average radial distance of an electron from the nucleus. Comparison of $\langle r_1 \rangle$ for two or more states of a given atom should indicate their relative radii. Also, as it is well known that the size of an atom is essentially determined by the outer shell⁴, the value of r_1 at the outer shell maximum of $D(r_1)$ could be taken as a measure of the size of an atom. Finally, the radius of a sphere containing a specified percentage of the total electronic charge is taken as a third index.

Consider the simple case of two electrons in a particular configuration in the field of a single nucleus. Figure 1 illustrates $D(r_1)$ for the singlet and triplet states arising from the $1s2s$ configuration of helium (the Pauli principle forbids a triplet state for the $1s^2$ configuration). The curves have been calculated for the moderately accurate correlated wave functions of Perkins⁵. The use of more accurate wave functions, such as those of Accad, Pekeris and Schiff⁶, which are nearly exact, would not alter the conclusions. On the basis of the indices listed in Table 1, it is clear that the helium atom is distinctly smaller by as much as 19% in the high spin 2^3S state than in the 2^1S state.

Similar calculations with the Perkins wave functions for Be^{2+} show that the 2^3S state is smaller than the 2^1S state by as much as 10%. (One curious result should be noted: in both He

Fig. 1 Radial density function $D(r_1)$ in the 2^3S (dotted line) and 2^1S (solid line) states of helium.

and Be^{2+} the value of r_1 at the L shell maximum of $D(r_1)$ corresponds to the radius of a sphere containing ~69% of the electronic charge in both the 2^3S and 2^1S states.) Very accurate values of $\langle r_1 \rangle$ have been reported⁶ for the singlet and triplet states of the $1sns$ and $1snp$ ($n = 2-5$) configurations of the helium isoelectronic sequence up to $Z = 10$. In every case, the triplet state $\langle r_1 \rangle$ is greater than the corresponding singlet value and, therefore, it must be concluded that for atoms with two electrons a high spin atom is smaller than a low spin atom with the same configuration and nuclear charge.

For atoms with many electrons, only a few wave functions have been reported with an accuracy approaching that obtained with atoms which have only two electrons. It is, however, well known that the Hartree-Fock method gives good charge distributions. Also, because the size of an atom is essentially determined by the outer shell, the size of atoms with many electrons can be discussed in terms of the radial density associated with the outermost orbital, in much the same way as atoms with two electrons have been discussed in terms of $D(r_1)$. Assuming that, and using Clementi's Hartree-Fock wave functions⁷, a high spin atom is found to be smaller than a low spin atom with the same configuration and nuclear charge, for all the states arising from the p^2 , p^3 and p^4 configurations of the partially filled L and M shells. The conclusion is valid for large atomic numbers. For example, qualitatively identical results are obtained for the 4S and 3P states of the $\text{K}(2) \text{L}(8) 3s^2 3p^3$ configuration of both P and Kr^{21+} .

Unfortunately, Clementi's tables⁷ include only the lowest state of the $\text{K}(2) \text{L}(8) \text{M}(8) 3d^n$ configurations and, therefore,

Table 1 Relative radii of the 2^3S and 2^1S states of helium (a.u.)

Index	2^3S	2^1S
$\langle r_1 \rangle$	2.55	2.97
L shell maximum	3.54	4.38
99% charge	8.75	10.23
95% charge	6.78	7.90
90% charge	5.67	6.75
80% charge	4.49	5.42
65% charge	3.24	3.98

cannot be used to discuss the spin states of biological interest. It would, however, be very surprising if results similar to those observed for p^n configurations were not also found for d^n configurations. This conjecture is supported by some results⁸ for the $K(2) L(8) 3s^2 3p^6 3d^1 4d^1$ configuration of Ca. The 4d radial densities indicate that Ca is smaller in the high spin 3F state than in the low spin 1S , 1D and 1G states. In this case, unlike the p^n configurations, there is a second allowed state which has the maximum multiplicity. Thus, the 3P state lies above the 3F and 1D states and leads to a correspondingly larger atomic radius.

Although it has long been realised that the effective radius of an atom depends on its electronic structure and environment⁹, it seems that the observations of free atoms discussed here have not been reported previously. Of course, environmental effects can be large and can lead to results opposite to those found in free atoms; a detailed discussion of environmental effects is, however, beyond the scope of this article.

Although these results are likely to be contrary to the 'chemical intuition' of many scientists, it should be noted that electron repulsion is greater in the triplet state than in the singlet state of some two-electron systems¹⁰ contrary to the usual interpretation of Hund's rule.

I thank Professor E. J. Wells for helpful correspondence.

Significance of the even-carbon n -paraffin preference of a Spanish crude oil

It has been suggested that processes other than the accumulation of biogenic hydrocarbons play an important role in the organic formation of petroleum. That can be inferred from a comparison of the different types of organic compounds found in sediments and petroleum^{1,2}.

Those studies dealt mainly with saturated hydrocarbons, among which n -paraffins have a special geochemical significance. That is because their distribution depends on the degree of maturity and the nature of the source material.

Most recent sediments exhibit an n -paraffin distribution concentrated between C_{18} and C_{32} , characterised by a marked predominance of odd numbers of carbon atoms ($CPI > 1$), (refs 3 and 4). As a result of physicochemical maturation processes, this predominance diminishes in the oldest sediments, and disappears in petroleum in which there is a shift in the maximum of the n -paraffin distribution curve towards lower carbon numbers. Thus, the CPI of a sediment is considered as an indication of its capacity for generating hydrocarbons³, although both the extent of generation of hydrocarbons and the type of source material, influence the distribution of the n -alkanes found in ancient sediments⁵.

Fig. 1 Gas chromatogram of the Amposta-marino crude oil (OV-101 capillary column).

Smooth n -paraffin distributions ($CPI \approx 1$) are typical of marine organic facies. A relative predominance of high molecular weight n -paraffins, with possibly an odd carbon preference in the C_{20} - C_{30} range has, however, been invoked as evidence of non-marine origin in some sediments^{4,6} and crude oils⁷⁻⁹. A slight predominance of odd number n -paraffin is not definite proof of continental origin, because it may have arisen by diagenetic processes¹⁰. The predominance of n -paraffins with odd numbers of carbon atoms has also been claimed to support the hypothesis of fatty acid decarboxylation in the generation of n -paraffins.

In our work on the chemical characterisation of the crude oils from the first oil field in production in the Mediterranean (near the mouth of the Spanish Ebro River), we have found that the Amposta-marino crude (Mesozoic, 16.6 API) apparently exhibits a marked predominance of n -paraffins with even numbers of carbon atoms within the C_{20} - C_{34} range (Fig. 1). That is interesting not only geochemically but also because it provides a means for the characterisation of accidental spillage of the crude oil in the sea¹¹.

We isolated the n -paraffins by separate treatment of the light distillates ($< 200^\circ C$) and of the desasphalted residue with 5 Å molecular sieves. Analysis by gas-liquid chromatography provided the real distribution of n -paraffins in the crude oil (Fig. 2). A maximum appeared at $n=8$, and a CPI value of 0.74 was observed in the range C_{24} - C_{34} .

Slight predominances of sedimentary n -paraffins with even number of carbon atoms have been reported^{4,12-14}. Considering the n -paraffin distributions found in living organisms (odd number preference), the even number predominances should be a result of post-depositional reductive processes acting on the organic matter, that is, hydrogenolysis of fatty acids^{4,12} and alcohols¹⁵. There is experimental evidence of such geochemical transformations¹⁶⁻¹⁸.

Even-carbon n -paraffins can also be formed by the condensation of two fragments originating from fatty acid decarboxylation or from n -paraffin thermal degradation^{19,20}. For thermodynamic reasons, however, these processes should be of secondary importance in comparison with true degradation.

Fig. 2 Distribution of n -paraffin in the Amposta-marino crude.

As far as petroleum is concerned only a very few cases of even-carbon predominances have been reported²¹. The most remarkable was found in a Nigerian crude oil within the C₄₀–C₄₆ range²². Its origin is very difficult to explain by the processes already mentioned.

To the best of our knowledge, there are no previously described examples of such a clear even-carbon number predominance within the C₂₀–C₃₄ range in crudes, as that exhibited by the Amposta-marino oil. The type of distribution shown in Fig. 2 leads to the assumption that the process of formation is not secondary but rather that the even-carbon number predominance is produced by the reduction of organic material containing large amounts of long chain fatty acids or alcohols. This could indicate a continental character in the crude oil, as would be expected for a deltaic environment. As long as no definite preference is observed in the C₁₂–C₁₈ region, the reduction of alcohols seems to be the more probable process.

Such a reduction has already been invoked, for example, to explain the formation of steranes from sterols in petroleum¹². Furthermore, the *n*-C₂₂ and *n*-C₂₃ paraffins, the principal hydrocarbons of the C₂₀–C₃₄ range studied, have been considered to be related geochemically to *n*-docosanol² and *n*-octacosanol¹⁵, the main components of some continental plants and sediments. On the other hand, the formation of even-number *n*-paraffins by the reduction of waxy alcohols could explain, in some cases²⁴, the balanced distribution of C₂₀–C₃₀ *n*-paraffins in old sediments and crude oils: it may result from dilution of the pre-existing odd-number compounds.

It is worth pointing out, in connection with these reduction processes, that phytane is more abundant than pristane in this crude (phytane/pristane=1.4), although it does not seem necessary to invoke a reduction process in order to explain this predominance, because of the existence of isoprenoid alkanes in living organisms.

In short, chemical and physical environments must be as important as time in establishing differences in the *n*-paraffin distributions. In particular, the manifest existence of reduction processes during the formation of the Amposta-marino crude affords direct evidence of the need for a reducing condition in the sediments for the formation of petroleum. This idea has been supported until now by the absence of olefins and other easily reducible substances in crudes. In any case, the mechanism of such processes has not yet been established.

Age of valley deposits in Périgord

IN Périgord, as in other parts of Europe, climatic and ecological variations inferred from Pleistocene sediments and organic remains have long provided the basis for correlating stratified Palaeolithic artefacts¹ and for subdividing the geological record^{2,3}. Radiocarbon dating now makes it possible to establish independent environmental, archaeological and palaeontological sequences and thus to investigate the links between them. I report here the results of work on valley deposits undertaken with this end in view; their archaeological and palaeoclimatic implications will be considered elsewhere.

Near their junction, the Vézère and Dordogne rivers and their larger tributaries (Fig. 1) display traces of three post-Tertiary depositional episodes separated by periods of erosion. Names are proposed for the resulting rock units (Fig. 2) to simplify discussion.

The 'Condat Tufa' is a localised deposit consisting of marls and tufas. Five ¹⁴C dates were obtained at various levels in the type section (section I), where the formation attains a maximum observed thickness of 8.2 m and overlies Jurassic limestones. (To judge from the published description this is the tufa at Coly from which Bourdier⁴ reported a temperate molluscan fauna.) The dates (Table 1) are consistent with their relative stratigraphical position and when plotted against depth indicate a uniform depositional rate of about 21 cm per 1,000 yr; but being on tufa they are automatically suspect. Variations in δ¹³C do not necessarily provide a good measure of the limestone dilution effect⁵ and in the present case yield no consistent pattern; and, as tufa is not forming today, a correction based on current ¹⁴C:¹³C ratios could not be introduced. As regards contamination by younger carbon, pretreatment with acid washes was supplemented by various analyses of the three uppermost samples. Although thin sections reveal no obvious evidence of recrystallisation, and X-ray diffraction shows that all three samples consist of calcite with less than 4 mol% MgCO₃, JD-22 displays some scattered rhombs of dolomite and signs of secondary calcitic cementation (P. Wigley, personal communication). This supports the inference that the high porosity (15–30% void ratio) of JD-21 and 22 coupled with their position at the surface of the tufa would have exposed them to ¹⁴C exchange, and thus argues for their rejection. Sample JD-2, being compact and rich in algal material, is more likely to yield a date which refers to the time of deposition.

The 'Montignac Formation' includes scree, colluvium and alluvium, and ranges in lithology from gravel to clay. Its surface slope attains 30° at some valley margins and decreases to form horizontal terraces along the larger streams, such as the Vézère at Montignac; its thickness commonly exceeds 25 m. The deposit is separated from the Condat Tufa by a weak unconformity; elsewhere it rests on Tertiary or older rocks. Although some aggradation may have taken place before the end of tufa deposition (unlike JD-2, samples JD-21 and JD-22 contain quartz grains), the bulk of the Montignac phase presumably postdates 21,730 BP. Derived Middle and Advanced Palaeolithic artefacts were found in the Montignac deposits at various exposures; at the Magdalenian open site of Solvieux, on the

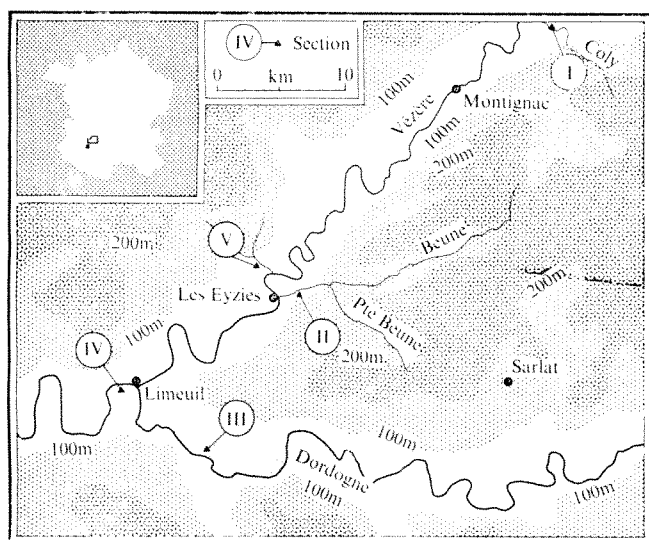

Fig. 1 Location map of places mentioned in text.

Isle (which joins the Dordogne west of the main area of study), deposition was apparently still in progress during the period of occupation. Radiocarbon dates for comparable material from the caves and shelters of Périgord⁶ suggest that deposition of the Montignac Formation continued until about 10,000 yr ago. It is worth noting that in the Beune valley, where the Montignac deposits are coarse in texture and slope down beneath the fine-grained material in which the river is now incised, a ¹⁴C date of 9,040 ± 60 yr BP (Grn-4492) has been obtained at a depth of about 13.7 m slightly above the contact between silty muds and the underlying sands and gravels⁷.

The 'Limeuil Alluvium' generally underlies the plains that border the larger streams, although it may be concealed by modern flood deposits. It consists principally of silty sand (whereas the flood material is dominated by coarse sand with abundant pebbles), and attains a maximum observed thickness of 7.5 m at Limeuil (section IV). Roman potsherds have been found within the deposit here as well as in a quarry west of Coux-et-Bigaroque (section III) and in the Beune opposite the cave of Font de Gaume (section II). Radiocarbon dating of the Limeuil Alluvium in the Manaurie valley (section V; see Table 1) has confirmed its historical age.

The resulting sequence may be summarised as follows. Localised tufa deposition came to an end about 21,000 yr ago. It was closely followed by a phase of scree formation, slope wash and valley filling. About 10,000 yr ago stream incision supervened. Renewed aggradation took place during or after Roman times, to be supplanted by the current erosional episode at some stage after AD 575.

Field mapping shows that the Montignac Formation of the present account includes most of the deposits attributed on the geological sheets of the area⁸ to the lower terrace of the *alluvions anciennes* as well as part of the *alluvions modernes*; the rest of the *alluvions modernes* correspond to our Limeuil Alluvium. Comparison with the accounts of Fénélon² and Bourgon³ shows similar discordances.

Chaput⁹ has described a deposit in the Garonne near its junction with the Dordogne similar in morphology and archaeological content to the Montignac Formation and linked to moraines at the foot of the Pyrenees which he ascribes to the Würm glaciation; the deposition of the Montignac Formation during glacial times, already suggested by its wealth in presumably frost-riven scree material, is further supported by the ¹⁴C dates of 17,500 and 9,700 BP obtained for peats laid down behind two of the outermost Pyrenean moraines¹⁰. The apparent absence in the area under review of valley deposits demonstrably older than the Condat Tufa, though surprising in view of the very long and complex sequence of glacial episodes that has been identified in the caves of Périgord¹¹, accords with the dearth of evidence for pre-Würm glaciations in the Pyrenees¹⁰ and with the finding that only one, 'rather recent', glacial phase is represented in the upper Dordogne¹². Moreover, neither Fénélon nor Bourgon succeeded in identifying slope deposits older than the Würm^{2,3}. As in the Mediterranean Basin¹³, we can either postulate that evidence for earlier glacial episodes has been destroyed¹⁴ or take the field record at its face value when attempting climatic reconstructions.

Fig. 2 Schematic section of valley fills.

I thank James Dartford and David Phillips for help in the field, Peter Wigley for X-ray and thin-section analyses, Lady Brogan for identifying potsherds, and Professor D. L. Thurber for advice. The Central Research Fund of London University provided financial support. Part of the work was done in conjunction with the British Academy Major Research Project in the Early History of Agriculture.

Grassland species can influence the abundance of microbes on each other's roots

NEIGHBOURING plants usually influence each other's growth. These interactions are very important in determining the composition and structure of plant communities, but much remains to be discovered about the mechanisms by which plants influence each other. Often plants compete for requirements such as light and mineral nutrients. Some plants exude substances which are toxic to others¹⁻³. Another possibility, as yet unexplored, is that interactions occur through changes in the microbial populations on the root surface or in the rhizosphere (the soil near the root surface). It is known that rhizosphere and root surface microorganisms can affect the plant's nutrient uptake and growth^{4,5}, but up to now there has been no evidence on whether plant species which naturally grow together can influence each other's microbial populations. We present here such evidence for two species common in British lowland grassland, *Lolium perenne* L. (perennial ryegrass) and *Plantago lanceolata* L. (ribwort plantain, a dicotyledonous species).

Seeds of the two species were collected from a permanent grassland site near Bristol. Soil was collected from a neighbouring field where both species also occur. The soil was mixed and placed in pots 13 cm in diameter; it was not sterilised, nor was fertiliser added. Seeds were germinated in vermiculite, and four seedlings were planted in each pot, either four *Lolium*, four *Plantago*, or two of each species.

Two similar experiments were performed. In the first there were nine replicate pots per treatment, and in the second ten. In the first experiment the plants grew from July until September 1973, and in the second from November 1973 to February 1974. The plants grew in a glasshouse for 2–3 months, and the roots were then washed free of soil. Randomly selected root segments were stained with phenyl acetic aniline blue and the abundance of bacteria and fungi on the root surface was determined by direct observation under a microscope: the percentage of the root area covered by bacteria was estimated in numerous randomly-positioned squares, and the length of fungal mycelium per unit root surface area was determined by the line intersection method⁶. The techniques are described in more detail elsewhere⁷. In the second experiment only fungi were determined.

Table 1 summarises the results. In every case the microbial abundance was greater when the two species were growing together than when they were separate, and by analysis of variance this main effect (separate/together) was always statistically significant. It is true that by Duncan's multiple range test only *Lolium* showed a significant increase in microorganisms in experiment 1, and only *Plantago* did so in experiment 2. Nevertheless, both species always showed the trend in the same direction.

We have no direct evidence on how (if at all) the increase in root surface microorganisms influences the higher plants, but the dry weights, shown in Table 2, are relevant. In experiment 1,

Table 1 Percentage cover of bacteria, and fungal mycelium length per unit root surface area, on root surfaces of *Lolium perenne* and *Plantago lanceolata* grown either separately or together

* Within each group of four, figures not followed by the same letter are significantly different (*P* < 0.05) by Duncan's multiple range test.

† Results of analysis of variance; ns, not significant.

Lolium showed an increased shoot weight in the mixture, while *Plantago* showed no change. The total yield by the mixture exceeded that of either pure stand (Table 2b). In experiment 2 there was a similar increase of weights in the mixture, though it was not quite statistically significant. These results differ from the commonest situation in direct competition, where increased growth by one species involves reduced growth by another. They could be caused by the increased microbial population having a beneficial effect on plant growth. Yield increases by mixtures, of the sort shown in Table 2b, have been reported previously, but do not always occur⁸⁻¹⁰. A recent survey of the literature on two-species and two-variety mixtures in pot and field experiments (E.I.N., unpublished), found that in 20% of cases the mixture yielded more than either pure stand. No satisfactory explanation has yet been offered as to why some mixtures show this increase and others do not, and it is possible that the nature of the microbial interactions is one of the factors determining this.

Table 2 Dry weight of shoots (g). Statistical significance expressed as in Table 1

a Mean weight per plant*.

	Experiment 1		Experiment 2	
	<i>Lolium</i>	<i>Plantago</i>	<i>Lolium</i>	<i>Plantago</i>
Separate	0.71 a	0.69 a	0.54 a	0.56 a
Together	1.01 b	0.69 a	0.71 a	0.62 a
Significance	<i>P</i> < 0.025		ns	
Separate/together	<i>P</i> < 0.025		ns	
Between species	<i>P</i> < 0.01		ns	
Interaction	<i>P</i> < 0.025		ns	

b Mean weight per pot (four plants)*.

	<i>Lolium</i> alone	<i>Plantago</i> alone	Mixture	Significance
Experiment 1	2.84 a	2.75 a	3.39 b	<i>P</i> < 0.025
Experiment 2	2.17 a	2.26 a	2.65 a	ns

* Letters (a and b) are for comparisons within each row.

Clearly the significance of our findings for higher plant growth is at present speculative. What we have definitely shown is that two plant species which commonly grow together can influence each other's root surface microbial population.

Catalysomes of adipose tissue are artefacts of enzyme localisation

WHEN adipose tissue (insect fat body and gut, mouse mesentery) is stained to localise esterases (using 5-bromoindoxyl acetate as indigogenic substrate³) or dehydrogenases (using various substrates and nitro-blue tetrazolium⁷) the reaction product forms a single cap on each lipid droplet^{4,9,11-13}. The cap has been thought to be an organelle¹², perhaps a specialised mitochondrion concerned in lipid metabolism², for which Wigglesworth proposes the term catalysome. Although the localisation of the reaction products in caps is very precise, the nature of the organelle has remained a mystery. In *Calpodes* fat body, 5-bromoindoxyl acetate always gives one perfect blue cap of the indigo reaction product for each lipid droplet (Fig. 1a) and similar localisation is obtained with the dehydrogenases (Fig. 1b), but further studies have shown that the catalysomes are artefacts caused by the preferential precipitation of reaction products in lipid or at lipid-water interfaces.

Our initial intention was to locate the caps by electron microscopy, and thus discover the nature of the organelle. In *Calpodes* larvae, the fourth instar lipid droplets disappear and are replaced by a new generation within 24 h of ecdysis to the fifth instar (ref. 5). Esterase caps can be demonstrated from the moment that the new generation of lipid droplets becomes visible by light microscopy, that is when they are about the size of mitochondria. Electron microscopy (EM), however, showed no organelle preferentially associated with lipid droplets at this time when such an association should have been unmistakable. Esterase localisation for EM by the 8-acetoxyquinoline/bismuth oxynitrate method of Deimling¹ also failed to identify any esterolytic organelle associated with lipid droplets. Bismuth was deposited in mitochondria spread throughout the cytoplasm, and within some droplets (Fig. 2) but no cap-like organelle could be discerned. The bismuth precipitate associated with lipid which in EM sections often appeared to spread from one or occasionally two foci on the periphery of a droplet (Fig. 2) was seen in whole mounts as a large number of spots on the surface of each droplet (Fig. 1c).

Our failure to locate the catalysome as well as the rather different intracellular localisation of esterase reaction product demonstrated by Deimling's method suggested that the validity of the methods that produced the original cap localisations should be checked. An alternative substrate for the indigogenic demonstration of esterases, 5-bromo-4-chloroindoxyl acetate, has greater affinity for protein which causes it to be retained more strongly at the site of esterase activity⁴. The cytoplasm of fat body cells reacted intensely when this substrate was applied (Fig. 1d), but there was no localisation in lipid or caps. The localisation of esterase reaction products in caps may therefore be an artefact resulting from lipid solubility of the indoxyl intermediate in the indigogenic reaction⁴. An attempt was made to reproduce the artefact on free lipid droplets by mixing them with esterase *in vitro*. Fat bodies were homogenised

Fig. 1 Distribution of enzyme reaction products in whole mounts of *Calpodes* fat body: Scale 10 μ m. *a*, Caps of indigo on lipid droplets from esterase demonstration with 5-bromoindoxyl acetate. Insert, indigo caps on olive oil droplets. *b*, Caps of diformazan on lipid droplets from NADH diaphorase demonstration using Nitro B.T. Insert, caps of diformazan on olive oil droplets. *c*, Surface spots of reaction product on lipid droplets from esterase demonstration by Deimling's method. *d*, Cytoplasmic indigo precipitate with no lipid association from esterase demonstration with 5-bromo-4-chloroindoxyl acetate.

in buffer and the homogenate centrifuged at 70,000g for 1 h to produce a discrete fat layer above a supernatant and pellet. The supernatant and pellet were taken from below the fat layer and added to the indigogenic reaction mixture (substrate 5-bromoindoxyl acetate) together with a small amount of olive oil which was dispersed by stirring. After 1 h the numerous lipid droplets less than 14 μ m in diameter all carried one indigo cap similar in appearance to those produced in intact fat body (Fig. 1a, insert). No indigo precipitates were obtained in a control mixture lacking esterase. Repetition of the experiment adding only the supernatant to the indigogenic reaction mixture also produced single caps on droplets.

Since esterase localisation in caps seems to be an artefact, the similar localisation of various dehydrogenases must also be questioned. Eight dehydrogenases have been reported to be localised in the caps on lipid droplets¹². But since the final reaction in all of these histochemical tests involves a common enzyme 'Nitro B.T. reductase' the existence of an artefact common to all reaction mixtures can be decided using a mixture for a single dehydrogenase. We chose to investigate the most active, NADH diaphorase. A homogenate of *Calpodes* fat body was prepared as described previously and two fractions taken from it, the supernatant and a mixed supernatant and pellet. These were added to the NADH diaphorase reaction mixture. After 1 h caps of formazan had formed on many lipid droplets in the mixture containing pellet and supernatant (Fig. 1b insert). In contrast to the indigogenic result two or more caps per droplet was the most common situation which suggests a difference from the localisation reported in tissue. In our experiments, however, incubations of live fat body to demonstrate NADH diaphorase generally resulted in a small number of caps per lipid droplet (Fig. 1b). No caps were produced on lipid droplets in the supernatant fraction, a predictable result since NADH diaphorase is considered to be mitochondrial. These experi-

Fig. 2 Reaction product (arrowed) localised in mitochondria and lipid droplets in *Calpodes* fat body from esterase demonstration by Deimling's method. Scale 1 μ m.

ments provide strong evidence that the cap localisation of dehydrogenases is an artefact of Nitro B.T. formazan's attraction for lipid-water interfaces. This attraction has been observed in histochemical practice⁶ and has been demonstrated recently *in vitro*¹⁰.

We thank Dr O. v. Deimling for providing the 8-acetoxyquinoline.

Genetic response to environmental heterogeneity

ONE of the major problems of contemporary population genetics is how to account for the large amount of genetic variation occurring in natural populations. Considerable controversy

exists between those people proposing that the variation is adaptively neutral, and those arguing that most of the variation is maintained by balancing selection. One of the processes of balancing selection postulated, is based on the idea that different genetic variants are favoured in different environmental niches. We report results from an experiment designed to test this hypothesis in which populations of *Drosophila* were exposed to experimental environments of various degrees of heterogeneity. The rationale is simple—if genetic variation is adaptively neutral, all populations should maintain about the same amount of genetic variation; if the 'environmental heterogeneity' hypothesis is correct, the degree of genetic variation in a population should be correlated with the degree of heterogeneity of its environment.

Eighteen population cages were started on August 20, 1972, each consisting of 423 *Drosophila pseudoobscura* that were F2 and F3 progenies of gravid females collected at McDonald Ranch, Napa County, California during May and June 1972. Two females and one male were introduced into each cage from each of 141 single female lines. The cages were similar to those described by Ayala¹ but each contained ten food cups. Four environmental factors were varied in the experiments: food, yeast, temperature and illumination (see Table 2 for the environmental treatments used). In four populations all four environmental factors were fixed for any one population. In the other 14 populations, one or more environmental factors were heterogeneous; that is, these populations were exposed to two kinds of food, and/or two kinds of yeast, and so on. The number of environmental factors varied were: one in four populations, two in five populations, three in two populations, and four in three populations. The cages were maintained for 1 yr (12-15 generations) at which time adult females were collected and assayed for genetic variability using the techniques of starch-gel electrophoresis². Twenty polymorphic enzyme loci were studied in all populations except for three cages which we had sampled for only 15 loci before they were destroyed accidentally. Forty-four individuals or 88 genomes from each population were assayed for each enzyme. All cages were assayed within 3 weeks.

Table 1 summarises the results. For each group of populations we calculated the average (over populations) of heterozygous individuals observed at each locus. There is a tendency for higher levels of heterozygosity in populations exposed to greater environmental heterogeneity. The heterozygosity among the groups of populations is significantly heterogeneous at only two loci, *Ald* and *Est-5*.

Table 1 also shows the average heterozygosity over the 20 loci studied for each group of populations. The average heterozygosity gradually increases as the number of heterogeneous environmental factors increases from zero to three, but it decreases from three to four. Given the large standard errors, heterozygosities would not be expected to reflect precisely the environmental effects. Yet, the overall trend towards increased heterozygosity with increased environmental heterogeneity seems well established; the average heterozygosities are significantly heterogeneous. An analysis of variance based on the locus heterozygosities for all cages shows that treatment (number of environmental factors heterogeneous) has a significant effect ($P \approx 0.01$). The heterozygosity values for each population have also been calculated using only the 15 loci assayed in all populations. The results do not differ in any significant way from those reported in Table 1.

The average proportion of heterozygotes per locus in the natural population from which the experimental flies were descended is 0.212 ± 0.041 for the 20 polymorphic loci studied. This statistic averaged over all 18 experimental populations is 0.184 ± 0.006 . In the experimental populations the amount of genetic variation has decreased somewhat on the average, although for some groups of populations the average heterozygosity is ostensibly very similar to that of the natural populations.

Table 2 gives for each environmental factor the heterozy-

§ $P < 0.005$.

gosities in populations exposed to each of two environments or to both. The values in Table 2 were obtained by averaging the average heterozygosities of the appropriate experimental populations. For every factor, populations exposed to heterogeneous environments have, on the average, greater amounts of genetic variation than populations exposed to uniform environments. The differences are highly significant for temperature and yeast, less so for food, and are statistically insignificant for light.

The idea that genetic polymorphism can be maintained by selection favouring two or more phenotypes in the same population is not new^{3,4}. Indeed, mathematical treatments of the subject have existed for 20 yr (refs 5 and 8). In spite of this early theoretical interest, field and laboratory data in support of multiple-niche polymorphism are far from extensive. The early work of Cain and Sheppard⁹ gave some indication that shell colour in *Cepaea* was related to the variety of habitats in which it was found. Likewise Da Cunha *et al.*¹⁰ presented evidence for a positive correlation between the frequency of gene arrangements in *D. willistoni* and the degree of habitat diversity. Laboratory experiments to demonstrate that polymorphism can be maintained by diversifying selection were carried out by Thoday and Boam¹¹ and Clarke and Sheppard¹² on the level of quantitative characters in *D. melanogaster* and *P. dardanus* respectively, and by Beardmore and his colleagues¹³ on the *esterase-6* locus in *D. melanogaster*. More recently Powell¹⁴ has reported the results of an experiment carried out in population cages with *D. willistoni*. Having an experimental design similar

to our own, Powell surveyed 13 populations for 22 enzyme loci and found that the average heterozygosity per individual was higher in populations maintained in heterogeneous environments than in populations in more constant environments. Since *D. willistoni* flies are polymorphic for multiple chromosomal inversions, however, it has been argued that the inversion polymorphisms and not the single loci may have been the direct targets of balancing selection in Powell's experiment¹⁵. This ambiguity does not arise in our experiment. The strains of *D. pseudoobscura* used to initiate our populations carry inversions only in the third chromosomes. Seventeen of the loci assayed in our study are located in chromosomes other than the third. The heterozygosities calculated using only these 17 loci are given in Table 1. Clearly, populations exposed to heterogeneous environments maintained more genetic variation than populations living in uniform environments. The parameters given in Table 2 have also been calculated for the 17 loci known to be in chromosomes other than the third. The results do not differ in any significant way from those obtained when all 20 loci are used.

Since our experiment was designed to test a model of selection we have taken care to minimise the role of random drift. Drift could have been a significant factor on the population heterozygosities if the population size were small at the start or at any time during the experiment. Each cage was started with 846 genomes (2×423 flies) descended from 282 wild flies (141 females and their mates); the number of flies in a cage was never smaller than 500.

In conclusion, our results indicate an overall positive correlation between environmental diversity and genetic polymorphism, and therefore support the notion that genetic variation is maintained in natural populations by selection.

Inferred slow inward current in snail neurones

A NUMBER of excitable membranes exhibit a long-lasting depression of the delayed outward current during a depolarising pulse. One explanation is that there is a true inactivation of potassium gates¹⁻³, and another is that it is due to an accumulation of potassium ions in a limited volume extracellular space, reducing the electric driving force for potassium ions^{3,4}. We have examined the relationship between the depression of net outward current and concomitant changes in potassium ion activity recorded with a potassium-sensitive microelectrode positioned close to the surface of monopolar ganglion cells of the snail *Helix pomatia*.

Experiments were performed on two bursting pacemaker neurones in the right parietal ganglion⁵. One of these produces no fast outward current⁶⁻⁹ and is therefore useful as a control for possible artefacts due to activation or inactivation of an additional outward current. Electrodes of 2-20 M Ω , filled with 3 M KCl, were inserted into exposed cell bodies. The preparation was bathed in Ringer's solution¹⁰ with 5 mM HEPES (N-2-hydroxyethyl-piperazine-2-ethane sulphonic acid; Servo, Heidelberg) buffer in place of Tris at a temperature of 13°C-15°C. The electrochemical activity of K⁺ was monitored at distances below 50 μ m from the visible cell surface with a double-barrelled potassium sensing electrode. One barrel contained the K⁺ selective resin while the other barrel, containing 0.15 M NaCl, acted as a reference for the pair¹¹. The resolution time constant for transients in K⁺ activity was below 20 ms. Membrane current during voltage clamping of the cell was measured with glass pipettes from a limited area of the soma surface (50-80 μ m in diameter) by the patch clamp technique¹². This avoided current transients from unclamped regions of the neurone. All signals were stored on tape and averaged by a Didac computer. Net charge transfer across the membrane (integral of the current signal) was compared with net K⁺ flux (time integral of the K⁺-activity signal).

The major features characterising depression of delayed outward current can be seen in Fig. 1a. Long depolarising pulses produced a delayed outward current which gradually decayed to about 60% or less of its maximum intensity with a time constant of 300 to 700 ms (refs 1, 7). The presentation of paired short pulses of equal amplitude and duration demonstrated that long term depression of the slow outward current persisted even though the voltage was returned to the holding level between a conditioning pulse (pulse 1) and a test pulse (pulse 2). For a time interval of up to 1 s, the delayed current produced by the second pulse sometimes even failed to reach the level of the current produced at the same point in time by the prolonged first pulse. Recovery from depression of the pulse 2 outward current occurred with a time constant of up to 10 s. The length of pulse 1 necessary to depress the test pulse current corresponded with the rise of the pulse 1 outward current. Prolongation of pulse 1 beyond its peak did not produce much further depression

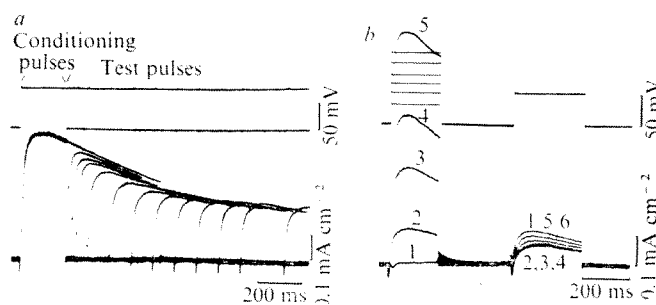

Fig. 1 *a*, Superimposed series of a conditioning, test pulse experiment. Voltage programme, at the top (holding potential -58 mV), current traces below. Pulse 1 is held at a fixed position while pulse 2 is delivered with various delays to show the envelop of the outward current depression. A single pulse of equal voltage but longer duration (650 ms) is also superimposed. *b*, Depression of pulse 2 current by increasing amplitude of pulse 1. Same cell and holding potential as in *a*. Small numbers identify corresponding sequences. Pulse 2 current slopes numbered 5 and 6 rise from considerably higher instantaneous currents as an aftereffect of the large pulse 1 currents. The pulse 1 current during the 120 mV step⁹ is not displayed.

of the pulse 2 current¹. This, together with the failure of sub-threshold conditioning pulses to produce the phenomenon, suggests that the activation of the current gates during pulse 1 may be causally related to the time-dependent depression of the pulse 2 outward current. Increasing pulse 1 further reduced pulse 2 currents, but only slightly (Fig. 1b). The maximum effect was reached at positive membrane voltages of pulse 1 (+40 to +100 mV).

The kinetics of closing of the activated gates at the termination of pulse 1 can be determined from the instantaneous current steps which appeared at the onset of subsequent pulses 2 at short intervals (Fig. 1a). The depression of pulse 2 current was much longer-lasting and must therefore have arisen by a different mechanism. In bursting pacemaker cells, the rising phase of pulse 2 outward currents is always considerably slower than that of pulse 1 (Fig. 2a, b), which may contribute to the failure of pulse 2 currents to reach the current level during maintained voltage steps (Fig. 1a). Although the pulse 2 outward current increased up to 30% if hyperpolarisation up to -150 mV preceded pulse 2, the retardation of the current remained and became more pronounced during the early part of the outward current trajectory.

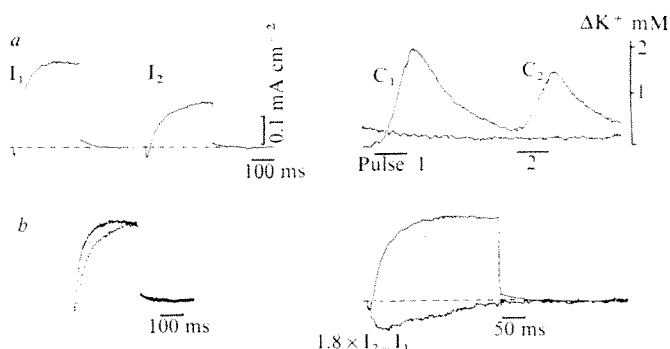

Fig. 2 *a*, Left, averaged pulse 1 and pulse 2 currents (I) ($n=8$) of a cell A during voltage steps of +45 mV from holding potential of -42 mV. The interpulse pause was 1 s. Right, simultaneously recorded extracellular K⁺ signals (C) in a continuous display. The tail K⁺ signal is superimposed. The prolonged slope from a sample of single pulses ($n=8$) at the same electrode position is marked by dots. Calibration of K⁺ signals is made with Ringer solutions with known K⁺ molarities^{1,11}. Note that current (left) and K⁺ signal (right) are displayed at different time scales. *b*, Left, currents normalised to same peak amplitude to show retardation in rising phase of pulse 2 current (digitalised display). Right, after normalisation, pulse 1 current subtracted from (enlarged) pulse 2 current; inward current downwards. Pulse 1 current is superimposed.

The long-lasting depression of outward current provided a convenient situation for comparing the depression of net outward current during pulse 2 with the concomitant reduction in K^+ accumulation at the outer neuronal surface using the K^+ -specific microelectrode (Figs 2-4). We standardised the pause between pulses 1 and 2 at 1,000 ms and delivered paired pulses at a repetition rate of once every 30 s to allow time for complete recovery from depression. The ratio $Q(2:1)$ was obtained by dividing the time integral of net outward current during pulse 2 by the equivalent integral during pulse 1 and was found to be 0.51 ± 0.12 (s.d.).

Since the outward current ceases almost immediately on termination of the pulse, accumulated extracellular K^+ (ΔK^+) should dissipate and its concentration fall progressively from the relatively early peak after the pulse is terminated. The role of K^+ accumulation was tested directly by measuring the K^+ activity with the electrode very near or just touching the visible cell surface during paired depolarising pulses. Single pulses were also applied to determine the baseline activity for the second pulse. After 1 s, when pulse 2 was initiated, the potassium signal evoked by pulse 1 was less than 15% of its peak value. Nevertheless, the outward current during pulse 2 was always depressed for periods longer than 1 s when the extracellular K^+ activity had approached even closer to pre-stimulus levels. Thus it seems unlikely that the depression of the pulse 2 net outward current is primarily due to extracellular accumulation of potassium ions.

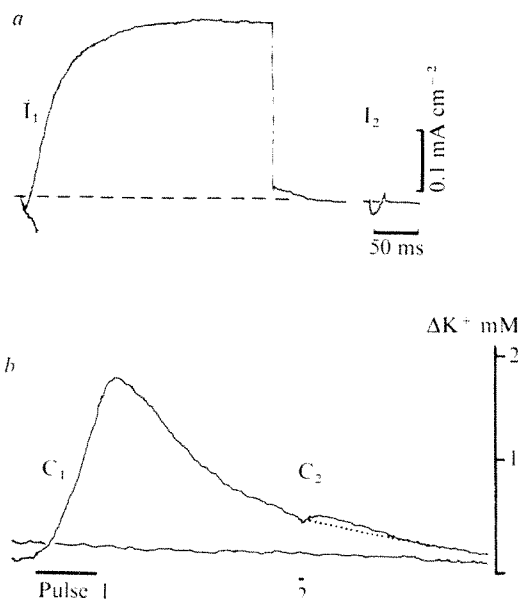

Fig. 3 Same experiment ($n=12$) and voltages as in Fig. 2, with pulse 2 of much shorter duration (20 ms). *a*, Current signal; *b*, K^+ activity signal. There is an obvious K^+ signal following pulse 2, concomitant with a predominantly inward going current during that pulse. Ratio of outward currents ($Q(2:1)$) is not proportional to the ratio of K^+ signals ($FK(2:1)$). Current and K^+ activity traces displayed at different time scales.

If it is assumed that the net outward current recorded under voltage clamp conditions is a pure potassium current, it follows that potassium activity changes recorded near the cell surface should parallel quantitatively the net charge transfer produced by the outward current. That is, the ratio $Q(2:1)$ should equal the ratio $FK(2:1)$ (K flux during pulse 2/ K flux during pulse 1) for any pair of pulses. From Figs 2 and 4 it is evident that $FK(2:1) < 1$; that is, K^+ efflux is reduced, as would be expected if the K channels are partially inactivated during pulse 2. Quantitative comparison, however, indicates that there is a 'deficit' in the net outward current of pulse 2 relative to the K^+ signal. In Fig. 2*a* this is obvious from the peak of the K^+ signal of pulse 2 which is more than half of the K^+ peak of pulse 1, whereas the ratio of the amplitudes of currents 2 and 1 is less than 0.5. This deficit ($FK(2:1) - Q(2:1)$) ranged from 0.10 to

0.25 in various units studied. The deficit in net current is most readily explained as the result of an inward current which makes its appearance during pulse 2 and shortcircuits a portion of the K^+ efflux. Such an inward current would result in a net charge transfer during pulse 2 lower than that transferred by K^+ efflux, and thus explain the deficit of net outward current recorded during pulse 2 relative to the K^+ signal.

The presence of a previously unrecognised slow inward current receives further support from a comparison of the kinetics of the outward currents of pulses 1 and 2 (Fig. 2*a, b*). The trajectory of the outward current characteristically has a slower rising phase during pulse 2 than during pulse 1 when the currents were normalised. (Normalisation was carried out by three methods. In the first, the pulse 2 current was simply additionally amplified to bring the current peaks of the two pulses to the same amplitude. In the second, the exponential falling phases of the current pulses were extrapolated back to the beginnings of the pulses and the pulse 2 current was then additionally amplified, so that the extrapolated decays began from the same amplitude. In the third method of normalisation the averaged pulse 1 current trajectory was reduced in proportion to the ratio $FK(1:2)$ and then subtracted from the averaged trajectory of pulse 2. Deficit currents determined by those three methods differed only slightly.) Comparison of current traces in Fig. 2*a* and 2*b* shows that the 'slow inward current' obtained by subtracting normalised pulses 1 from pulses 2 has a far slower time course than the fast inward current.

The difference in the trajectory of the outward current of pulses 1 and 2 was displayed by electronically subtracting, after normalisation, the averaged trajectories of pulse 1 currents from those of the enlarged pulse 2 currents from the same neurone (Fig. 2*b*). The result is a trajectory with a peak 20 to 50 ms after the onset of the current pulse, that is, during the rising phase of the outward current of pulse 1. The time integral of this deficit in pulse 2 current in the different cells was -0.08 to -0.21 times that of the corresponding pulse 1 currents and was always found comparable with the deficit in net outward current obtained by determining $FK(2:1) - Q(2:1)$.

We conclude that the long-term suppression of net outward current by a conditioning pulse consists of two components. The chief component is a true time and voltage-dependent inactivation of the delayed potassium system, similar in some respects to the inactivation of the sodium system described by Hodgkin and Huxley¹³. It is also manifested as a reduction in pulse 2 extracellular potassium accumulation relative to accumulation during pulse 1. Since it develops during interpulse periods with pulse durations approximating the duration of the action potential (Fig. 4), the inactivation contributing to the depression of outward current described here seems more likely to have functional importance under physiological conditions than any reduction in outward current which may be produced by the extracellular accumulation of K^+ with prolonged depolarising pulses⁴. The second component contributing to depression of delayed outward current during pulse 2 seems to be a previously unrecognised inward current which partially shortcircuits the outward potassium current. Its existence is supported by several independent lines of evidence: first, the reduction in K^+ efflux during pulse 2, resulting from a true K^+ inactivation, is smaller than the reduction in net outward current (Fig. 2*a*); second, at any given time after pulse 1 (up to 1 or 2 s) the peak outward current produced by pulse 2 does not reach the level of outward current produced at that time by the prolongation of pulse 1 (Fig. 1*a*). In addition, the rising phase of pulse 2 exhibits slower kinetics than that of pulse 1, consistent with a superimposed delayed inward current (Fig. 2*b*).

Certain molluscan neurones have a fast outward potassium current which is activated by conditioning hyperpolarisation and inactivated by depolarisation⁶⁻⁹. Inactivation of a fast current might produce the observed slowing of the pulse 2 outward current. This source of artefact can, however, be ruled out for several reasons, the most important of which is the use of bursting pacemaker cells (Figs 1-3) which fail to show a fast out-

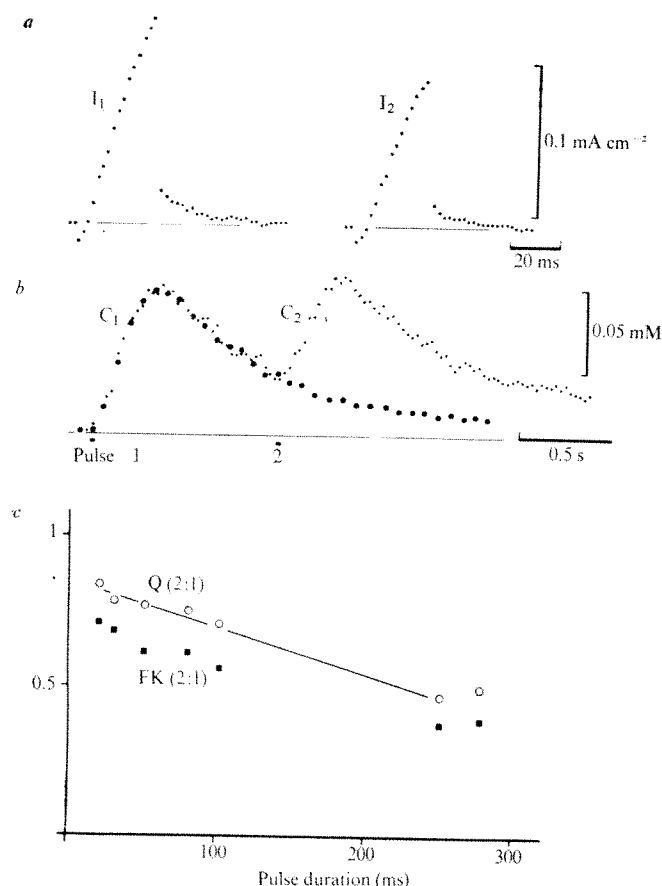

Fig. 4 *a*, Currents 1 and 2 evoked by +65 mV steps each of 30 ms duration from a holding potential of -45 mV. Simultaneous sampling of K^+ signals is shown in *b* ($n=25$). The superimposed averaged trajectory of single pulses is given by heavier dots. *c*, Ratios of pulse 2 to pulse 1 outward current integrals ($Q(2:1)$) and corresponding ratios of potassium fluxes ($FK(2:1)$) of this cell plotted as a function of pulse duration. Duration of pulse 1 and 2 was kept equal and was varied in unison. At shorter pulse durations the difference between K^+ flux and charge transfer ($FK(2:1) - Q(2:1)$) becomes smaller, but does not disappear.

ward current even if given a strong hyperpolarising conditioning pulse. Also, the deficit of pulse 2 outward current relative to measured K^+ accumulation cannot be explained by the inactivation of a fast outward current. In cells with a fast outward current this deficit was seen whether or not the fast outward current was activated.

The delayed inward current is difficult to identify and measure during pulse 1; its appearance or augmentation during pulse 2 has been demonstrated by using the pulse 1 current as a control for the pulse 2 current. It is nevertheless interesting that the activation of this inward current, unlike the other membrane current components, is facilitated by a preceding depolarisation. The two components of delayed outward current depression, true inactivation of the K^+ system and activation of a slow inward current, presumably both contribute to the progressive increase in spike duration, overshoot and positive shift in post-spike undershoot, which occur during the initial half dozen or so spikes of the train comprising a 'burst'. The ionic identity of the slow inward current and its possible role in neuronal bursting remain to be ascertained.

Neuromuscular blocking action of an alkylating local anaesthetic: site of action and effects of temperature and calcium ions

THE mechanism by which local anaesthetics block neuromuscular transmission has been under investigation for many years. Most of the evidence suggests that these drugs act primarily on nerve terminals either to inhibit acetylcholine (ACh) release¹⁻³ or exert some other effects⁴. However, other workers have shown inhibition of ACh receptor^{5,6} or direct depression of muscle excitability⁷⁻¹⁰. Inhibition of nerve conduction apparently has been ruled out as contributing to the blockade in rat phrenic nerve-diaphragm³ or cat soleus nerve-muscle preparations⁴.

In an attempt to determine the primary site of action of these drugs we have used the recently synthesised β -haloethyl amine compound, 2-[(2-chloroethyl) methylamino] ethyl 4-ethoxybenzoate, which irreversibly blocks nerve conduction¹¹ as well as neuromuscular transmission¹². We report here that when phrenic nerve-diaphragm transmission is irreversibly blocked, the compound has essentially no effect on the excitability of nerve or muscle. From this we conclude that the action of the irreversible local anaesthetic in this preparation is confined to the junctional region.

The rat phrenic nerve-diaphragm preparation was set up by conventional means¹³ for stimulation of the muscle either directly or through the nerve (indirect). Figure 1 shows the effect of the compound on contractions elicited by both types of stimulation: the compound blocked indirect contractions with no effect on directly elicited contractions. This occurred whether the drug was in the bath or removed by washout. When the phrenic nerve was removed at the time of irreversible block of indirect contractions, it still maintained excitation and conduction properties. Irreversible block of these electrical responses *in vitro* required a concentration of drug about five times greater than that needed for irreversible block of transmission¹¹.

These findings show that blockade of transmission by the compound is confined to the junction. The physico-chemical properties of the compound probably account for this selective action, unlike procaine which depresses both direct and indirect contractions concomitantly. At the pH of the bath we used (7.4) the compound exists almost exclusively in the aziridinium or positively charged form¹² and thus cannot penetrate well to the active membranes of nerve or muscle. On the other hand, the compound evidently can readily reach the unmyelinated nerve terminal membrane or post-junctional region, where it combines irreversibly with some receptor.

• If the drug was washed out after a fairly short time of contact with the tissue, for example, 10 min, the observed

Fig. 1 Neuromuscular blocking action of 2-[(2-chloroethyl)methylamino]ethyl 4-ethoxybenzoate, 0.2 mg ml^{-1} , applied to rat phrenic nerve-diaphragm preparation. Even in the presence of the drug, the directly elicited contraction was unaffected. On the other hand, the indirect twitch was abolished. The irreversible nature of the latter effect is indicated by the complete block even 2 h after washing.

block of contraction was reversed completely, indicating a two step inhibitory mechanism similar to that observed with other receptor alkylating agents¹⁴.

If the tissue was pretreated with decamethonium or *d*-tubocurarine at concentrations sufficient to block transmission completely, application of the compound still resulted in irreversible blockade after washout. This procedure has been shown¹⁵⁻¹⁷ to protect the active site on the ACh receptor against irreversible reaction with α -bungarotoxin. Based on this finding, we think it most likely that a receptor for local anaesthetics exists on the nerve terminal and that it can undergo the same type of alkylation reaction exhibited by receptors for neurohormones.

To obtain thermodynamic data for reaction with the receptor, the temperature dependence of rate of irreversible block of transmission was determined as follows. Before the drug was added, the nerve was stimulated with gradually increasing voltage, from threshold to the maximum for eliciting contraction of the muscle. This gave control voltage-response curves. This procedure was repeated at various times after the drug had been added to the bath and washed out, giving data for the irreversible change in

Fig. 2 Semi-log plot of rate of irreversible block of indirectly elicited twitch of the phrenic-nerve diaphragm by 2-[(2-chloroethyl)methylamino]ethyl 4-ethoxybenzoate. Rate of block was determined from midpoints of the voltage-response curve after washing out the drug (see text for details). □, k at $30^\circ \text{C} = 0.037 \text{ min}^{-1}$; △, k at $15^\circ \text{C} = 0.30 \text{ min}^{-1}$.

sensitivity. The initial effect of the drug was to shift the voltage-response curve to the right without reducing the maximum; with increasing time, the maximum declined and ultimately contractions could not be elicited at any voltage. The midpoints of the curves were plotted as log percentage change in voltage against time; straight lines were obtained (Fig. 2).

It is interesting that the rate constant at 15°C was much greater than at 30°C ; this was not anticipated since alkylation reactions would be expected to show a positive temperature dependence. Other findings indicated that the actual rate of reaction of the drug with the receptor is much lower at the low than the high temperature. If the tissue was incubated with the drug at 15°C to give complete irreversible block and the temperature raised to 30°C , transmission was completely restored (Fig. 3). This indicates that during the time of reaction at 15°C only a small fraction of the receptors had reacted, but this was sufficient to produce the complete block at this temperature. Another possibility is that reversal of block was due to cleavage of the drug-receptor bond at the higher temperature. To test this, the degree of reversal was determined when the temperature was progressively raised from 15° to 30°C and then lowered back to 15° (Fig. 4). The two curves are almost identical and thus the reversal of the block produced by raising the temperature was not due to a change in receptor occupancy. In addition, if the drug was applied at 30°C for a time during which no significant irreversible shift in the voltage-response curve was observed; lowering the temperature to 15°C resulted in inhibition of contractions.

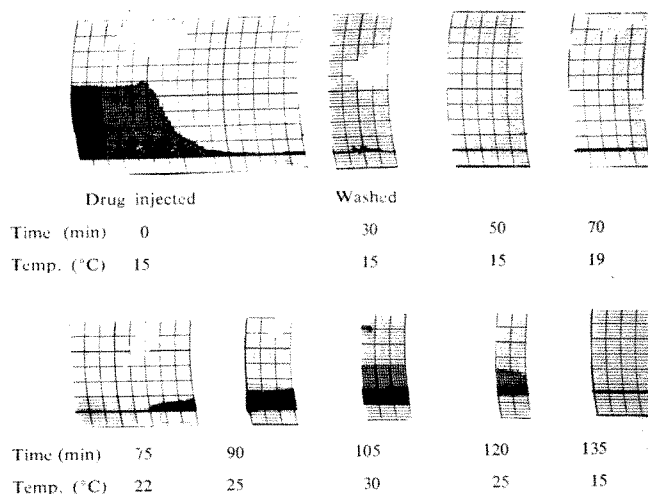

Fig. 3 Effect of increasing temperature of bath after application and washout of 2-[(2-chloroethyl)methylamino]ethyl 4-ethoxybenzoate, 0.2 mg ml^{-1} , for 30 min. The indirect twitch was irreversibly blocked at 15°C and progressive increase in temperature resulted in relief of block. At 30°C the response was almost that of the 30°C control, which usually was somewhat smaller than at 15°C . Reduction of the temperature back to 15°C resulted in return of the block.

These results indicate that the number of receptor acting irreversibly is directly related to temperature as the rate of block is inversely temperature dependent. Thus the rate of receptor alkylation cannot be determined pharmacologically since there appears to be no relationship between absolute number of receptors and the degree of neuromuscular block. This was supported by the fact that although the same number of receptors was occupied by the drug at 15° and 30°C , the block differed. One possible explanation for the block at the lower temperature in spite of the same fraction of receptors occupied is that fewer nerve terminals are involved in transmission at the lower

Hence, occupation of a smaller fraction of nerve terminal receptors would be sufficient to block contractions. In support of this concept, Taylor reported that the output of acetylcholine is about 80% lower at 20°C as compared with 37°C in this preparation¹⁸.

It is well documented that curare-like drugs also show an inverse temperature dependence for potency of neuromuscular blockade^{18,19}. This has been interpreted in terms of a temperature-dependent dissociation of the drugs from the ACh receptor¹⁹ or to temperature dependent solubility

Fig. 4 Effect of progressive increases of temperature from 15°C to 30°C (□) and the subsequent return to 15°C (●) on a preparation blocked irreversibly at 15°C. The degree of irreversible block was not significantly affected by the increase in temperature, and thus the appearance of contractions did not result from dealkylation of receptors.

Fig. 5 Effect of increasing calcium ion concentration on change in sensitivity of indirectly elicited contraction by the alkylating local anaesthetic (□) and by procaine (○). Sensitivity (V) is the voltage required to produce half-maximum contraction as determined after applying the drugs for 10 min. An increase in ΔV indicates that the calcium increased the potency of the drug, that is a greater voltage was required to produce half-maximum contraction. A decrease in ΔV signifies antagonism of the drug by calcium.

of the drugs in the post-synaptic membrane²⁰. We have found that blockade of transmission by procaine shows a similar inverse temperature dependence. In view of the results reported here for the irreversibly acting compound, the explanation for temperature dependence of blockade by reversibly acting drugs may have to be revised.

The effects of calcium on the voltage-response curve of the alkylating compound and on procaine are shown in Fig. 5. In this concentration range, calcium had no effect on excitability of the preparation. Calcium ions had a biphasic effect on the irreversible compound, promoting its potency at low concentrations, inhibiting its blocking action at higher concentrations. On the other hand, calcium only inhibited procaine blockade of transmission. The potency of the alkylating compound was also enhanced when the preparation was stimulated tetanically or if the potassium ion concentration was increased. These conditions produce nerve terminal depolarisation. Since the compound was present primarily in the quaternary ammonium form, it would not penetrate well through the nerve terminal membrane. Penetration seems to have been promoted by depolarising conditions as manifested by the enhanced potency observed. These results are in harmony with Narahashi's evidence that the site of action of local anaesthetics is the inner surface of nerve axon membranes²¹. Higher concentrations of calcium ions probably reduce the rate of irreversible reaction of the aziridinium compound with its receptor by a competitive mechanism as observed on various nerve axons for reversible local anaesthetics^{22,23}.

Temperature-sensitive mutation affecting myofilament assembly in *Caenorhabditis elegans*

THE assembly of contractile and calcium-related regulatory proteins into functioning myofilament arrays within muscle cells and the genetic control of muscle differentiation are still largely unknown processes¹⁻³. Here we present evidence that a particular gene may regulate such lattice assembly in the body wall muscle cells of the nematode *Caenorhabditis elegans*. A temperature-sensitive mutation in this gene can prevent the appearance of normal myofilament lattices in this muscle without affecting the amounts of major contractile proteins present. The organised or defective adult structures once formed in mutant muscle are stable to changes in temperature.

The recessive mutation *e286* is induced by ethyl methane-sulphonate on chromosome III of *Caenorhabditis elegans* (strain collection of Dr Sydney Brenner)^{4,5}. This mutagen has proved of great use in producing temperature-sensitive mutations in *Drosophila*⁶. *N₂* (wild type) nematodes are highly motile between 15° and 25° C. The locomotive and reproductive rates of these animals increase over this temperature range. In contrast, when grown above 20° C, *E286* animals are paralysed with only very slow body movements apparent and they reproduce at a diminished rate. At 15° C, the movement and growth of *E286* mutants is indistinguishable from *N₂* populations. At both temperatures, the pharyngeal muscle in mutants behaves normally. *+ / e286* heterozygotes are not affected behaviourally or structurally by growth at either temperature. Thus, one genic dose of normal function is sufficient to overcome the presence of a mutant gene or its product.

If mutant eggs (chitin-encased embryos) are permitted to develop and hatch at 15° C, switching the temperature to 25° C will lead to paralysed larvae and adults. Conversely, mutant embryos hatching at 25° C will develop into motile adults by growth at 15° C. Such reversal of phenotype can be performed throughout the four larval stages of these nematodes. Behavioural reversibility at the *L₁* stage is demonstrated in Table 1. But when the sexually mature adult stage is reached, the phenotype is stable to temperature change within the above range. Maintenance of paralysed adults at 15° C or of motile adults at 25° C for periods up to several days (compare to 3 d generation time) does not alter either body movement, or the characteristic body wall muscle structure of either form (Fig. 1). Motile *E286* adults have body wall muscle cells exhibiting periodic sarcomeric structures such as A bands, I bands, dense bodies, and H zones that are very similar to *N₂* muscle elements as observed with the polarised light microscope. Paralysed *E286* adults do not exhibit these regular structures in their body wall muscle. When the body wall muscle cells of *E286* animals grown at either temperature are examined by electron microscopy, ultrastructural differences between the two populations are observed. The 15° C specimen demonstrates thick filaments encircled by parallel arrays of thin filaments (Fig. 2). The paralysed 25° C animal also possesses recognisable thick filaments. In this case, there does not seem to be any specific orientation of thin filaments. Fibrous structures of dimensions appropriate to thin filaments appear at various angles to the thick filament array.

This mutation seems to be affecting the formation of myofilament arrays during muscle growth periods as evidenced by temperature reversibility of phenotype during larval development. Adult muscle having constructed its myofilament arrays or not is then unaffected by this temperature-sensitive mutant function. Thus, the instability of a permanent component of muscle is probably not responsible for the loss of structure and function at high temperature.

Fig. 1 Living animals were picked off lawns of *Escherichia coli*, OP50, and suspended in a 10 μ l drop of 0.8 Ascaris Ringer's solution (24.5 mM KCl, 11.8 mM CaCl_2 , 9.8 mM MgCl_2 , 3.9 mM NaCl, and 125.1 mM sodium acetate). A No. 1 or No. 1.5 glass coverslip was then placed over the drop. All observations were performed on a Reichert Zetopan research microscope fitted with strain-free objective and condenser. The uncalibrated magnification determined by instrumental and photographic settings was $\times 746$. *a*, *N₂* grown at 25° C; *b*, *E286* grown at 15° C; *c*, *E286* grown at 25° C. All observations were made at an ambient temperature of about 23° C.

The relative migration and amounts of several myofilament proteins of *E286* grown at either temperature and of *N₂* are similar to one another when separated according to molecular weight on sodium dodecyl sulphate-polyacrylamide gel slabs⁷. But a difference in a catalytic or minor structural protein present in low relative concentration or an alteration not affecting molecular weight would not be observed with this method.

Table 1 Reversibility of E286 locomotive behaviour

Temperature, condition* (° C)	No. of animals	Time (s) for 50 beats†
15	20	20.9 ± 1.8
25→15	20	31.2 ± 8.4
25	16	157 ± 74
15→25	16	189 ± 106

*Animals were either grown through adulthood at one temperature or switched at L₄ stage. All observations were of adults.

†One beat is defined as the formation of a semicircle by flexion at the mid-body when the animal is suspended in 0.8 Ascaris Ringer's solution. Note that about two thirds of the 25° C animals did not make any such movements and were not scored. The movements of 25° C and 15°→25° C animals that were motile at all were so slow that less than 50 beats were usually measured and then normalised to 50. Such biases may lead to underestimation of the time and greater variability in the paralysed cases.

What kind of function is altered by *e286*? The most attractive hypothesis is a defect in a catalytic function necessary for proper myofilament arrays to form, consistent with the fully recessive behavioural and morphological phenotype of E286 at 25° C. Mutation in a *cis* acting control element regulating synthesis of a myo-

fibrillar component would also explain the recessive character but would be unlikely to produce temperature sensitivity, whereas alteration of a structural protein which at 25° C prevented assembly might be expected to have a semi-dominant phenotype. Further biochemical and structural studies of E286 and the search for additional mutations within this gene are being pursued for better understanding of this function.

Fig. 2 Nematodes were grown on *E. coli*, OP50, lawns at either temperature. Living adults were cut in half, fixed in cold phosphate-buffered glutaraldehyde, and post-fixed in cold Veronal-buffered osmium tetroxide^{8,9}. Thin sections of body wall muscle cells were photographed on an AEI EM63 electron microscope. The uncalibrated magnification was $\times 14,400$. The dimensions of thick and thin myofilaments are about 2.4 and 0.6 nm, respectively^{8,10}. *a*, E286 at 15° C; *b*, E286 at 25° C.

Genetic complementation after fusion of Tay-Sachs and Sandhoff cells

THE N-acetyl- β -D-glucosaminidase (hexosaminidase) activity in cultured human fibroblasts consists of at least three components (A, B and C)¹⁻³. At least two of these (designated Hex A and Hex B) seem to be closely related, for (1) antiserum against Hex A reacts against Hex B, and *vice versa*^{1,3} (2) in Tay-Sachs disease only Hex A activity is deficient, accompanied by an increase in Hex B activity in certain tissues^{1,6}, and (3) both Hex A and Hex B activities are missing in Sandhoff disease, another autosomal recessive disorder⁷. But in spite of several theories⁸⁻¹¹, the precise relationship between these components remains unknown, as does the nature of the genetic and biochemical relationships between the two diseases. To investigate these questions we have fused Tay-Sachs with Sandhoff fibroblasts and obtained cultures containing heterokaryons which produce a hexosaminidase which is absent from the parent lines. It has the electrophoretic and heat lability characteristics of the Hex A found in normal fibroblasts.

Skin fibroblasts from a patient with Tay-Sachs disease (G.M. 221) and a patient with Sandhoff disease (G.M. 203) were obtained from the Genetic Mutant Repository, Camden, New Jersey, and experiments were carried out with cells at the eighth to eleventh passage. Electrophoretic analysis of extracts of these cells confirmed that the Tay-Sachs fibroblasts lacked Hex A, while the Sandhoff fibroblasts under our experimental conditions has neither Hex A nor Hex B. On rare occasions faint traces of Hex A and

Fig. 1 N-acetyl- β -D-glucosaminidase electrophoresis. (1) Normal control fibroblasts; (2) virus-treated Sandhoff fibroblasts; (3) virus-treated Tay-Sachs cells; and (4) mixture of Sandhoff and Tay-Sachs fibroblasts cultivated together without virus fusion. The electrophoretic analysis was carried out on cell extracts using a slight modification¹³ of the CelloGel method of Rattazzi and Davidson¹⁴.

B could be detected in the Sandhoff fibroblasts when they had been maintained without subculturing for more than 15 d. In addition, both cell lines had, at times, Hex C^{2,3,11}, which in our experience appears only in cultures maintained for 5 or more days without transfer, the actual time apparently depending on the initial cell concentration.

In a series of fusion experiments (Table 1), fibroblasts from the two parental lines, after trypsinisation, were resuspended in Hanks salt solution without glucose. Cells were mixed in a ratio of 2:1, that is 4.8×10^6 Sandhoff cells to 2.4×10^6 Tay-Sachs cells. These cell mixtures, as well as separate aliquots of Tay-Sachs and Sandhoff fibroblasts, were exposed to β -propiolactone-inactivated Sendai virus¹² in the cold for 15 min. Cells were then resuspended in medium (Eagle's minimal essential medium with non-essential amino acids, penicillin, streptomycin and 15% foetal calf serum) and plated in a series of 60 mm plastic Petri dishes (10^6 – 10^8 cells per dish). In addition, mixtures of the parental lines (2 Sandhoff:1 Tay Sachs) not exposed to virus were plated into dishes as another control.

Sixteen to 24 h after fusion, cover slips in dishes containing the virus-treated Sandhoff–Tay-Sachs cell mixtures were fixed and analysed for the presence of multinucleated cells (Table 1). Cells from experimental and control dishes were collected at various times after fusion for the electrophoretic analysis of hexosaminidase activity (Table 1). The cells were washed twice with phosphate-buffered saline (PBS), trypsinised, and, after centrifugation, washed again with PBS. Each pellet was suspended in 0.05–0.2 ml (de-

pending on cell concentration) of 0.01 M citrate-phosphate buffer, pH 7.0, and disrupted by ultrasonication (three 10-s treatments). The ruptured cells were centrifuged for 10 min at 5,000g at 3–5° C and the supernatant was used for biochemical studies.

Without virus treatment, the cocultivation of the parental lines in a ratio of 2:1 (Sandhoff to Tay-Sachs) for as long as 16 d yielded Hex B, and in time Hex C, but no Hex A (Fig. 1). Virus-treated Tay-Sachs fibroblasts also showed Hex B, and on prolonged culture the C band, but never Hex A. The virus-treated Sandhoff cells showed neither Hex A nor Hex B, but on prolonged culture they also had Hex C.

In contrast, the virus-treated mixtures of parental lines had, in addition to the expected Hex B, a band comigrating with Hex A (Fig. 2). The latter appeared in one experiment as early as 24 h and in all cases seemed to increase to a maximum between 3 and 6 d after fusion (Table 1 and Fig. 2). The activity of Hex A seemed to correlate with the number of multinucleated cells present in the culture and declined when the nondividing heterokaryons had been overgrown by mononuclear parental cells.

As this new A-like band might represent a modified form of Hex B or C, its thermal lability was examined. Cell extracts were incubated under conditions in which the Hex A activity is destroyed while most of the Hex B activity remains. We found that the novel component formed by the virus-treated Sandhoff–Tay-Sachs mixture had the heat lability of the Hex A found in normal fibroblasts (Fig. 3).

We suggest that the novel band produced by virus-induced heterokaryons is the Hex A enzyme lacking in both parental lines. A more positive identification awaits the development of sensitive and specific assays involving antibodies or labelled substrates.

It is conceivable that the substance responsible for the appearance of this novel band is passed through the medium from heterokaryon to deficient parental cells. But, even when Sandhoff or Tay-Sachs cells were exposed for 2–11 d to medium in which virus-treated cell mixtures had been proliferating for at least 3 d, no evidence of Hex A was found. Furthermore, neither incubation of mixtures of cell extracts from the two parental lines at 37° C for up to 144 h, nor prolonged exposure of lysates from one parent line to proliferating cells of the other, resulted in the production of Hex A.

Fig. 2 N-acetyl- β -D-glucosaminidase electrophoresis. (1) Extract from normal fibroblasts and (2–6) extracts from virus-treated mixtures of Tay-Sachs and Sandhoff fibroblasts 16, 24, 48, 72, and 144 h after fusion. The novel band shown in this figure comigrates with Hex A when mixed with extracts of control fibroblasts.

Fig. 3 Cellogel electrophoresis of cell extracts before and after incubation in 0.01 M phosphate-citrate buffer; pH 7.0, for 45 min at 52° C. Extract of normal fibroblasts before (1) and after (2) incubation; extracts of virus-treated Tay-Sachs-Sandhoff mixture before (3) and after (4) incubation.

Our results (Table 1) suggest that this enzyme persists in these heterokaryons for as long as 16 d, at a time when the cell population contains relatively few heterokaryons. Conceivably the product responsible for the appearance of the activity passes from heterokaryon by cell-mediated contact to surrounding parental cells or alternatively is stored for prolonged periods, as reported for β -glucuronidase¹⁵.

The mechanism underlying the appearance of the novel enzyme, believed to be Hex A, is uncertain. Perhaps the Sandhoff cells provide either an enzyme to convert the Hex B of Tay-Sachs origin into Hex A, or a subunit essential to the formation of Hex A. On the other hand, the Tay-Sachs cells might stabilise in some way a labile Hex B and Hex A of Sandhoff origin.

We have not attempted to isolate mononuclear hybrid cells because of the lack of an effective means to select against either parental cell.

Nevertheless, our studies of the heterokaryons derived

from Tay-Sachs and Sandhoff cells show that even in the absence of selection this approach can reveal intergenic complementation. Complementation tests have already provided evidence of genetical heterogeneity contributing to the phenotypes of galactosemia, xeroderma pigmentosum, and maple syrup urine disease¹⁶⁻¹⁸. The study of the interaction between different genomes within the heterokaryon, not only reveals genetical heterogeneity, but also indicates directions to follow in pursuit of the underlying disease mechanism.

Solvent exposure of specific nuclei of angiotensin II determined by NMR solvent saturation method

CONFORMATIONAL analysis of peptides in solution by nuclear magnetic resonance (NMR) spectroscopy generally involves determination of the relative exposure to solvent of specific NH hydrogens¹⁻⁴. The four methods used so far are based on: (1) rates of NH proton exchange with labile hydrogens of the solvent⁵⁻⁶; (2) temperature dependence of chemical shifts of NH resonances⁷⁻⁸; (3) dependence of NH chemical shifts on the composition of a suitable solvent mixture⁹⁻¹¹, and (4) degree of resonance broadening when a paramagnetic substance is added¹². Each method has limitations. Proton exchange rates reflect not only exposure to solvent,

but also proximity to functional groups of the peptide which catalyse exchange. Factors which determine the temperature dependence of NH chemical shifts are as yet poorly understood. Changes in solvent composition can alter the conformation of the peptide¹¹. Paramagnetic ions may associate preferentially with the solvent or with specific sites on the peptide.

We suggest here a method which offers the advantage of measuring the solvation of both NH and CH hydrogens while not physically altering molecular structure. This involves monitoring intensity changes of solute resonances resulting from saturation of the solvent resonance. Intensities of solute resonances originating from exposed labile hydrogens exchanging rapidly with the solvent are diminished by transfer of saturation¹³⁻¹⁶, whereas resonances of exposed nonexchangeable hydrogens are enhanced by a positive nuclear Overhauser effect (NOE)¹⁷. Although the method is generally applicable to any solute-solvent pair having suitable nuclei, it is particularly appropriate to investigations of peptides and other biomolecules in aqueous solution. Here we describe its application to the interaction of water with the pressor hormone (Asn¹, Val⁵) angiotensin II (AII'), whose primary structure appears in Fig. 1. Materials and the correlation spectroscopy technique used have been described before^{16,18,19}.

Transfer of saturation is governed by equation (1)

$$(M_\alpha^a - M_\alpha^b)/M_\alpha^a = [T_{1\alpha}/(T_{1\alpha} + \tau_a)] [(M_\beta^b - M_\beta^a)/M_\beta^b] \quad (1)$$

which was derived from modified Bloch equations using a procedure analogous to that used by Gupta and Redfield²⁰. The α and β states refer to solute and solvent nuclei, respectively, which are chemically exchanging. $T_{1\alpha}$, τ_a , M_α^a and M_α^b are the spin-lattice relaxation time, life time, observed magnetisation and equilibrium magnetisation of the α nucleus, respectively. Analogous notation is used for the β nucleus. $(M_\alpha^a - M_\alpha^b)/M_\alpha^a$ is the fractional decrease in resonance intensity of the α resonance resulting from double irradiation of the β resonance, whose intensity is diminished by a factor of $(M_\beta^b - M_\beta^a)/M_\beta^b$. Complete saturation of the β state causes a fractional decrease of the α resonance equal to $T_{1\alpha}/(T_{1\alpha} + \tau_a)$, which is significant only if the pseudo-first order rate constant for exchange of the α nucleus, $1/\tau_a$, is comparable with or greater than its relaxation rate, $1/T_{1\alpha}$. Measurement of the extent of saturation transfer and $T_{1\alpha}$ facilitates estimation of the exchange rate.

Saturation of the solvent resonance also results in positive NOEs for resonances originating from solute hydrogens exposed to the solvent or in close proximity to solute hydrogens experiencing saturation. Saturation of solute resonances can result either from exchange-mediated transfer of saturation from the solvent or from coincidence of solute and solvent resonances (which is usually also caused by rapid exchange with the solvent). Three mechanisms can contribute to the observed NOE: (1) direct dipole-dipole interaction between solute and solvent hydrogens (such intermolecular dipole-dipole effects have been observed, and a theoretical treatment of this phenomenon has been derived by Krishna and Gordon)²¹, (2) dipole-dipole interaction between the monitored hydrogen and a nearby partially or completely saturated solute hydrogen, and (3) scalar coupling between the monitored hydrogen and a solute hydrogen which is exchanging with the solvent at a rate comparable to the chemical shift difference between the two coupled solute hydrogens¹⁷. This exchange-modulated scalar coupling would yield a negative NOE (decrease in resonance intensity), whereas the dipolar mechanisms yield positive NOEs except when long correlation times are encountered (for example, macromolecules)²².

Figure 1a shows the region of the spectrum of AII' to low field of the water resonance when saturation power is applied 1,200 Hz to high field of the solvent peak. Resonance assignments are those obtained in this

laboratory^{16,23,24} and by Bleich, *et al.*^{25,26}. Saturation of the water resonance yields the spectrum shown in Fig. 1b. Figure 1c shows the difference (amplified) between the solvent saturated and the off resonance irradiated spectra (Fig. 1b-Fig. 1a). Negative peaks originate from solvent exposed labile hydrogens experiencing transfer of saturation—Arg² peptide NH , Asn¹ *trans*-amide NH , and Arg⁷ guanidino NH s. The Arg² peptide NH , Asn¹ amide NH and Arg⁷ guanidino NH resonances decreased in intensity by factors of 0.50 ± 0.05 , 0.09 ± 0.03 and 0.07 ± 0.02 , respectively. Positive peaks originate from solute hydrogens experiencing a positive NOE—His⁶ C_αH , His⁶ C_βH , Tyr⁴ *o*-CH and perhaps also the Phe⁸ $\text{C}_\alpha\text{H}_2$ (overlap with the His⁶ C_βH peak obscures this resonance). The His⁶ C_αH and Tyr⁴ *o*-CH peaks experienced fractional enhancements of resonance intensities of 0.17 ± 0.05 and 0.12 ± 0.03 , respectively. Larger NOEs might be obtained by minimising relaxation pathways not associated with solute-solvent interactions, for example, by degassing the sample or using partially deuterated samples. Perturbation of His⁶ and Tyr⁴ peptide NH peaks results from partial decoupling of their corresponding α -CH resonances, which are close to the solvent peak.

Transfer of saturation indicated that the NH protons of Arg² exchange rapidly with the solvent and are therefore

Fig. 1 a, Low field region of the 250 MHz PMR spectrum of AII' (6.9% (w/v)) in H_2O , pH 3.0 ± 0.1 , at 31.5°C . The spectrum was obtained by correlation spectroscopy (twenty scans) with saturating rf power applied 1,200 Hz to high field of the solvent resonance. Chemical shifts are referred to the methyl resonance of sodium 2,2-dimethyl-2-silapentane 5-sulphonate. b, Same as (a) but with the solvent peak saturated. c, Spectrum (b) minus spectrum (a) amplified thirteenfold.

probably well solvated. Rapid exchange of these hydrogens has been noted previously^{16,23,28}. Partial saturation of the Asn¹ *trans*-amide NH suggests that this hydrogen is also exposed to the solvent. Taken together the data for Asn¹ and Arg² suggest that the two N-terminal residues of AII are relatively well solvated. This conclusion is consistent with our report that the *pK_a* of the Asn¹ amino group is comparable with that of similar solvated functional groups^{23,24}.

Observations of positive NOEs indicates that the dipolar mechanisms dominate over any exchange-modulated scalar coupling which might be contributing to the relaxation of the His² imidazole CH and Tyr⁴ *o*-CH protons. These protons must be in intimate contact with the solvent and (or) the nearby exchangeable protons on the side chains of these residues must be substantially saturated as a result of rapid exchange with the solvent. In either case a solvated environment is indicated for these CH protons since dipolar relaxation depends on the inverse sixth power of the internuclear distance. Solvation of the imidazole and phenol of AII¹ is consistent with the normal *pK_a*s of these groups^{23,24,27,28}. Failure to observe an NOE from the Tyr⁴ *m*-CH hydrogens may indicate that this portion of the phenol group is not in contact with water. These studies show how solvent saturation effects can delineate the extent of solvation of both labile and nonexchanging hydrogens.

We thank Dr Werner Rittel of Ciba Pharmaceutical Company (Basel, Switzerland) for AII¹, and Drs Sidney L. Gordon, Askel A. Bothner-By, and Raj K. Gupta for criticism of the manuscript. This research was supported by an established investigatorship (to G.R.M.) from the American Heart Association and a grant from the National Institutes of Health.

Ferritin synthesis in normal and leukaemic leukocytes

SERUM ferritin concentration is normally directly related to body iron stores^{1,2} but abnormally high values are also found in patients with leukaemia³. The greatest amounts are present in patients with acute myeloblastic leukaemia and in this condition the concentration within circulating leukocytes is about six times higher than in normal leukocytes⁴. We have demonstrated an abnormally high rate of overall ferritin synthesis in leukaemic cells. Previous studies in other tissues have shown that ferritin synthesis is closely related to iron supply, but this does not seem to be the case in either normal or leukaemic leukocytes where production of the protein is independent of iron concentration and the protein formed contains little, if any, iron.

Peripheral blood leukocytes were obtained from healthy adults and patients with acute myeloblastic leukaemia by sedimentation and differential centrifugation⁴. In synthesis experiments the white cell pellet was suspended in Eagle's minimum essential medium (MEM) at a concentration of 2×10^6 cells ml⁻¹, to which 20% foetal calf serum and 1 μ Ci ¹⁴C-leucine were added. Cultures were incubated in triplicate at 37° C under 5% CO₂ in air for 22 h. Controls consisted of omitting the cells from the incubation medium or the addition of cycloheximide at a concentration of 10⁻⁴ M. At the end of the incubation, the cells were sonicated and dialysed against five changes of 0.3% saline for 3 h. One hundred micrograms of human spleen ferritin were added and the total volume brought to 9 ml. A 2 ml aliquot was removed and the protein precipitated with 10% trichloroacetic acid followed by heating at 90° C for 15 min. The precipitate was washed with trichloroacetic acid and finally dissolved in 0.1 M NaOH before scintillation counting. Ferritin was isolated by heating the cell extract containing carrier ferritin at 70° C for 10 min, followed by centrifugation at 1,300g for 10 min. Anti-human spleen ferritin was then added to the supernatant, incubated at 37° C for 1 h and left at 4° C overnight. The precipitate was

Fig. 1 ^{14}C -leucine incorporation into ferritin at different iron concentrations. The iron content of the basal medium is $0.67 \mu\text{g}$ per 2×10^6 cells. ▼, Chang cells; ●, leukaemic leukocytes (left hand scale). ■, Normal leukocytes (right hand scale).

washed three times with 0.9% saline and dissolved in 0.5 M HCl before scintillation counting. Chang liver cells³ (Flow Laboratories) were grown in MEM with 10% foetal bovine serum. Ferritin synthesis was measured under the same conditions and with the same cell concentration used with leukocytes. Sucrose density gradient fractionation of ferritin was carried out by the method of Drysdale and Munroe⁶. Twenty fractions of 0.5 ml were collected and ferritin was determined either by immunoradiometric assay or by the absorbance at 280 nm.

^{14}C -leucine incorporation into ferritin and total protein is expressed as c.p.m. per 10^6 cells. In seven normal subjects, the mean ferritin uptake was 54.2 ± 5.5 c.p.m. and the mean protein uptake $1,876 \pm 190$ c.p.m. The protein-ferritin ratio was 35.7 ± 4.1 . In seven patients with acute myeloblastic leukaemia, the mean ferritin uptake was 230.8 ± 36.6 c.p.m. and protein uptake $7,526 \pm 1,140$ c.p.m. with a protein-ferritin ratio of 33.0 ± 2.3 . Increasing the iron concentration in the medium from 0 to $10.0 \mu\text{g ml}^{-1}$ had no effect on ferritin synthesis in either normal or leukaemic cells. In experiments using Chang liver cells, a similar increase in iron concentration in the medium resulted in stimulation of ferritin synthesis (Fig. 1).

The largest amounts of purified human spleen ferritin appeared between fractions 8 and 11, in nine separate experiments. In three experiments using normal leukocyte extract, and six experiments using leukocyte extracts from patients with acute myeloblastic leukaemia, the maximum concentration of ferritin appeared in fraction 2 to 4 (Fig. 2) corresponding to apoferritin.

These results demonstrate increased ferritin synthesis by leukaemic cells and supports the suggestion that this is the cause of the raised serum and leukocyte ferritin concentration⁴ in leukaemia patients. Experimental studies on the control of ferritin synthesis have been carried out largely on liver cells and in this tissue, ferritin synthesis is closely related to iron supply⁶. Ferritin synthesis *in vitro* by HeLa cells is also stimulated by iron⁷ and *in vivo* studies have shown a similar iron dependence of ferritin synthesis by rat hepatoma⁸. Ferritin synthesis in Chang cells shows marked stimulation by iron, but without any increase in overall protein synthesis. In normal leukocytes, ferritin synthesis does not seem to be stimulated by increasing concentrations of iron, and leukaemic cells show the same insensitivity. In leukaemic cells, ^{14}C -leucine incorporation into ferritin takes place at about four times the normal rate and this seems to be a reflection of increased protein synthesis by these cells.

The characteristics of leukocyte ferritin on density gradient centrifugation suggests that this is either apoferritin or protein with a very low iron content. It has

been known for some time that the ferritins in different tissues may vary in their physical characteristics and probably their subunit composition. Linder-Horowitz *et al.*⁹ showed that the stimulation of ferritin synthesis by iron varies in different organs, being more marked in liver and heart than in kidney. While the iron content of liver ferritin remains constant that of heart and kidney ferritin falls with increased synthesis of the apoprotein. In the female rat heart, where there are two separate ferritins, the electrophoretically slow variant shows less response than the fast variant to stimulation by iron. In a study of abnormal ferritins in rat hepatomas, Linder *et al.*⁸ showed that protein induction by iron was less than in normal regenerating liver. Increasing growth rate of the tumours was associated with decreased iron uptake, a decreased concentration of ferritin in the tumour and a lower iron content of the ferritin. It was suggested that ferritin of low iron content might be characteristic of tissues undergoing rapid cell division but the possibility also exists that in malignant tissue, expression of an alternative gene locus for ferritin

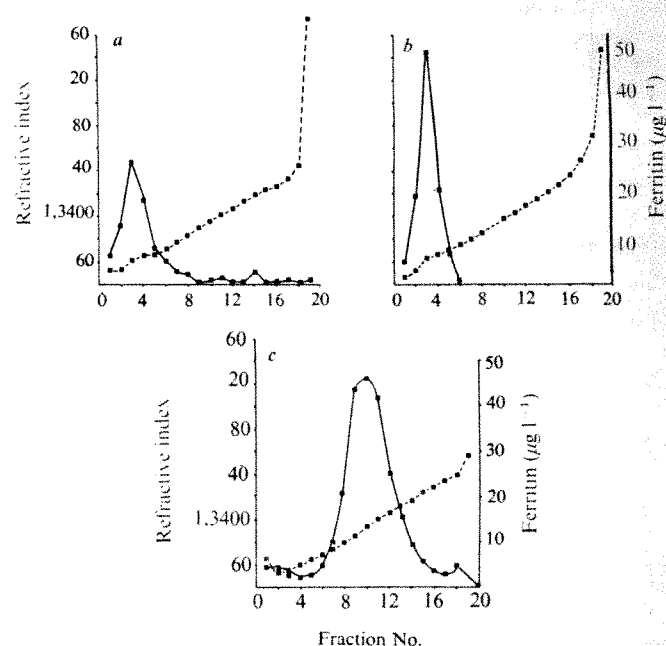

Fig. 2 Density gradient sedimentation of ferritin. ■—■ ferritin; ■—■ refractive index of medium. a, Normal leukocytes; b, leukaemic leukocytes; c, human spleen ferritin.

occurs and that this is associated with a low affinity of the protein for iron. The observation that synthesis in both normal and leukaemic leukocytes is not stimulated by iron and that the protein has the characteristics of apoferritin suggests the existence of a specific leukocyte ferritin. Its increased synthesis in acute myeloblastic leukaemia and its subsequent release into the plasma reflects the overall increase in protein synthesis by leukaemic cells and may provide a useful marker for the progress of the disease.

β , γ Unsaturated amino acids as irreversible enzyme inhibitors

IRREVERSIBLE enzyme inhibitors whose mechanisms of action are based on the k_{cat} term rather than on K_s are highly specific. Inhibitors of this type possess hidden reactive moieties which are unmasked enzymatically. On generation, the reactive product engages in a chemical reaction with an active site residue resulting in irreversible inactivation of the enzyme. Thus, the enzyme produces its own irreversible

Fig. 1 Inactivation of aspartate amino transferase by AMB. Aspartate amino transferase from pig heart (Sigma Chemical Co.), specific activity 234 units mg^{-1} (where one unit of enzyme will convert 1 μmol of α -ketoglutarate to glutamic acid per min at 25°C) was used. In these experiments 0.008 units of enzyme (■) were incubated at 25°C in 0.1 M potassium phosphate buffer, pH=7.6 with 10 mM AMB. At the times indicated, 5 μl of the enzyme was removed and its activity determined by the standard assay system containing aspartic acid, α -ketoglutaric acid, NADH and malic dehydrogenase⁶. Identical experiments were performed in the presence of 0.2 M aspartic acid (▲) and in the absence of AMB (●) (control). The activity of the inactivated enzyme was not restored by dialysis against the phosphate buffer with several changes over a 36 h period attesting to the enzymes being irreversibly inactivated. Furthermore, the activity of the inactivated enzyme could also not be restored by incubation with 1 mM pyridoxal phosphate for several hours.

Fig. 2 The ultraviolet spectra and inactivation of aspartate amino transferase by AMB. In a 1 cm cuvette 936 units of enzyme in 1 ml (0.1 M potassium phosphate at pH=6.0) was charged with 10 mM AMB at 25°C. The ultraviolet spectra of the sample were determined at the indicated times on a Cary 118 double beam spectrophotometer. The activity of an aliquot of the enzyme was determined by the standard method⁶ and compared with an untreated control. Inset shows the inactivation profile at the indicated times.

inhibitor from a chemically unreactive substrate. Inhibitors of this type will be referred to as k_{cat} inhibitors, and several synthetic inhibitors of this type have been reported¹. Here I describe an example of a naturally occurring molecule which acts by this mechanism: specifically, the irreversible inhibition of soluble, pyridoxal linked, L-aspartate amino transferase by the bacterial toxin L-2-amino-4-methoxy-trans-3-butenoic acid (AMB) isolated from *Pseudomonas aeruginosa*².

Incubation of soluble L-aspartate amino transferase with AMB led to the inactivation of the enzyme as shown in Fig. 1. The substrate, in this case L-aspartic acid, protects against this inactivation when co-incubated with AMB (Fig. 1) and is consistent with the view that AMB is an active-site titrant. Also, activity of the inactivated enzyme cannot be restored by dialysis. This observation means that the mode of inhibition is irreversible.

The assertion that AMB requires chemical activation suggests that no inhibition should result in the absence of enzymatic conversion. This is confirmed in that neither holoenzyme in the pyridoxamine form nor apoenzyme, are in the least affected by AMB. The notion that the inactivation step requires enzymatic conversion can be directly demonstrated by following the ultraviolet absorption changes of the holoenzyme as a function of its inactivation (Fig. 2). As the inactivation proceeds, both the activity and the spectrum of the enzyme were recorded and as can be seen, the fall of the pyridoxal phosphate imine peak (approximately 440 nm) and the rise of the new peaks at approximately 350 nm are simultaneous with the inactivation course. The appearance of the peaks at 350 nm are unusual and cannot be pyridoxamine phosphate ($\lambda_{max}=325$ nm) (ref. 3). These new peaks represent a reaction product, or complex, between the converted AMB and cofactor. This may mean that the inhibitor functions by reacting with the cofactor. This was tested by trying to resolve the inactivated holoenzyme into apoenzyme and cofactor by the usual method⁴. The 'resolved' enzyme still retained an absorption peak centred at 350 nm, representing about 30% of the total. This peak cannot be diminished even under forced resolution conditions. Of primary importance is that the resolved enzyme cannot be reactivated by incubation with fresh pyridoxal phosphate, therefore the primary action of AMB must involve a chemical reaction with an active-site amino acid residue. Of secondary importance is the formation of a further reaction pro-

duct(s) with the cofactor. Had a chemical reaction simply ensued between the cofactor and AMB, 70% of the activity should have been regained after fresh cofactor was added to the resolved enzyme.

Fig. 3 Initial steps in the catalysis with aspartate and α -ketoglutarate as substrate.

The initial steps in the catalytic process effected by aspartate amino transferase with aspartate and α -ketoglutarate as substrates are shown in Fig. 3 (ref. 5). With AMB as a substrate the conversions shown below can intervene once the α C—H bond is cleaved (Fig. 4). That both (B+B') and C are exceedingly reactive chemically is important because they can act as Lewis acids in the Michael reaction. The carbon atoms indicated with stars * designate where reaction would occur. The conversion shown in equation 1 is preferred on the basis of its being a normally occurring one for the enzyme, and is more consistent with the spectral changes which occur during the course of the inactivation process. Also, it is apparent that these proposed reactive intermediates are chemically bi-functional; for example, B', being a conjugated enol ether, can undergo two successive reactions with nucleophiles. This is precisely what is required here, because a minimum of two reactions must occur—one with an active-site

residue and one with the cofactor—to account for the spectral changes and the inactivation process.

In conclusion, AMB has been shown to be a potent irreversible inhibitor of the k_{cat} type, the first naturally-occurring toxin to be reported as such. It is likely that this is in no sense unusual but that other β,γ unsaturated acids will be found to be irreversible inhibitors of many pyridoxal-linked enzymes involved in amino acid metabolism, and that other naturally occurring toxins will also be found to be k_{cat} inhibitors.

I thank Edie Miller for technical assistance and Dr James P. Scannell of Hoffman-LaRoche Inc. for the gift of AMB.

Chelating agents for the binding of metal ions to macromolecules

POLYAMINOCARBOXYLATE chelating agents such as ethylenediaminetetraacetic acid (EDTA) form stable chelate complexes with the ions of many heavy metals. These metal ions exhibit a wide range of useful spectral and radioactive properties, such as electronic absorption, scattering of electrons and X rays, electron paramagnetic resonance spectra, the production of line-broadening and chemical shifts in nuclear magnetic resonance spectra, the emission of correlated gamma-ray cascades and various radioactive lifetimes and nuclear radiations. The preparation of chelating agents whose complexes can interact, in some selected manner, with biological macromolecules could make possible several new applications of metal ions as probes of biological systems.

The synthesis of 1-(*p*-aminophenyl)-EDTA (Fig. 1, R = NH₂) is a step toward this goal. In principle, its aromatic amino group can be acylated, alkylated or otherwise modified to form biologically active molecules or covalent labelling reagents. The specific interaction between a precursor of this compound, 1-(*p*-nitrophenyl)-EDTA (Fig. 1, R = NO₂), and an antibody molecule has been described previously¹.

We describe here the use of a derivative of the amino compound, 1-(*p*-benzenediazonium)-EDTA (Fig. 1, R = N₂⁺), as a reagent for labelling proteins. We also present data bearing on the usefulness of proteins labelled covalently with ¹¹¹In chelates as radiopharmaceuticals for the localisation of tumours.

The synthesis of 1-(*p*-aminophenyl)-EDTA (Fig. 1, R = NH₂) was accomplished in six steps, starting from benzaldehyde (details will be furnished on request). The amino compound then was diazotised² to form the chloride salt of 1-(*p*-benzenediazonium)-EDTA, or ⁺N₂Ph-EDTA (Fig. 1, R = N₂⁺).

The ⁺N₂Ph-EDTA was coupled to human serum albumin or to bovine fibrinogen (Blombäck fraction I-4 (ref. 3)) by reaction overnight at 4° C with 2% protein solutions in aqueous 0.01 M EDTA/0.12 M NaHCO₃ buffer, pH 8.1. The buffer ions and any

Fig. 4 Possible conversions of the catalytic product with AMB as substrate.

Fig. 1 The chelating agents discussed in the text.
R = NO₂, NH₂, or N₂⁺.

unbound reagent then were removed by extensive dialysis against heavy-metal-free 0.1 M citrate, pH 6. The presence of azotyrosine groups in the products was indicated by increased absorbance at 330 nm. Citrate buffer was chosen to facilitate the chelation of carrier-free ¹¹¹In ions by protein-bound -N₂Ph-EDTA groups. In this buffer, indium ions do not undergo hydrolysis or bind to native serum albumin or fibrinogen, but do bind readily to the conjugated proteins.

Indium-binding was studied experimentally by the technique of γ -ray perturbed angular correlations (PAC), using the ¹¹¹In ion as a radioactive probe of molecular motion¹. Based on the coincidence detection of γ rays emitted in cascade from a single nucleus, PAC depends on the rotational correlation time for fluctuating electric field gradients at the radioactive nucleus. The binding of ¹¹¹In ions to macromolecules is revealed by a change in the measured value of the integral perturbation factor, $\overline{G_{22}(\infty)}$. For carrier-free ¹¹¹InCl₃ in 0.1 M citrate at pH 6, $\overline{G_{22}(\infty)} = 0.60 \pm 0.01$, a value consistent with an indium complex of low molecular weight (in the same buffer, the NO₂-Ph-EDTA chelate of ¹¹¹In yields $\overline{G_{22}(\infty)} = 0.58 \pm 0.02$). For a similar solution containing 1% bovine fibrinogen, $\overline{G_{22}(\infty)} = 0.57 \pm 0.02$, indicating little interaction between indium ions and the macromolecule. For 1% human serum albumin, $\overline{G_{22}(\infty)} = 0.59 \pm 0.02$. When 0.3 ml of a 2% solution of human serum albumin, which had been reacted with an equimolar amount of +N₂Ph-EDTA, was added to 0.3 ml of citrate buffer containing ¹¹¹InCl₃, binding was complete in less than 1 min. This was indicated by the perturbation factor; $\overline{G_{22}(\infty)} = 0.40 \pm 0.01$, a value which was not changed by further addition of the conjugated albumin. The addition of 1% bovine fibrinogen, which had been reacted with a two- to three-fold excess of +N₂Ph-EDTA, to ¹¹¹InCl₃ in citrate led to complete binding within several minutes; the equilibrium value of $\overline{G_{22}(\infty)}$ was 0.37 ± 0.02 .

Albumin and fibrinogen differ greatly in molecular size and shape; yet, the perturbation factors for ¹¹¹In bound to the two labelled proteins are quite similar. This suggests that in each case the link between chelate and macromolecule is flexible⁴.

We have determined the organ distribution and tumour uptake of radioactivity after injection of the ¹¹¹In-labelled proteins into specially prepared BALB/c mice. A tumour line, KHJJ, derived from a primary mammary carcinoma arising spontaneously in a mouse and maintained for over 100 transplant generations was used for the assay⁵. Three mice were injected with each compound, and the per cent dose per gram of organ was measured 24 h after injection. Results are given in Table 1, together with data obtained using commercial ¹³¹I-labelled human serum albumin in the same model system. These data suggest that proteins conjugated with -N₂Ph-EDTA chelates will be useful radiopharmaceuticals. The observed tumour:organ radioactivity ratios would be favourable for scanning studies on human patients, and the radioactive properties of ¹¹¹In are ideal for providing scans up to 1 week after administration with a minimum of radiation exposure to the patient^{6,7}. In addition, PAC studies can provide direct information on the stability *in vivo* of ¹¹¹In-labelled compounds⁸.

The mild reaction conditions and rapid metal-binding achieved here suggest that +N₂Ph-EDTA will be useful for labelling

Table 1 Distribution and uptake of labelled macromolecules in BALB/c mice with KHJJ Tumour

Organ	¹¹¹ In-albumin	¹¹¹ In-fibrinogen	¹³¹ I-albumin
Blood	4.6 ± 0.6	6.7 ± 1.1	6.8 ± 1.6
Lungs	3.4 ± 0.6	3.1 ± 0.3	3.4 ± 1.2
Liver	8.6 ± 0.3	9.2 ± 0.5	1.1 ± 0.3
Spleen	3.3 ± 0.1	7.0 ± 0.7	0.7 ± 0.2
Kidneys	11.4 ± 0.1	18.1 ± 1.9	2.4 ± 0.6
Tumour	9.7 ± 0.3	8.1 ± 0.8	3.3 ± 1.0
Muscle	0.8 ± 0.2	0.8 ± 0.2	0.9 ± 0.2
Bone	2.0 ± 0.4	1.9 ± 0.4	1.0 ± 0.5
Brain	0.2 ± 0.1	0.3 ± 0.1	0.2 ± 0.1
Skin	2.4 ± 0.4	2.0 ± 0.3	—

Each of the compounds listed was injected into three BALB/c mice which carried a KHJJ tumour (implanted in the flank 14 d before). The tumours were about 1 cm³ in volume. Twenty-four hours after injection, the mice were killed and samples of blood and major organs were taken, weighed and counted. Results are reported in terms of per cent total dose per gram organ, a measure of the concentration of radioisotope in the various tissues.

biologically active molecules with short-lived radioisotopes. Related chelating agents have potential applications to a broad range of problems. A full account of this work will be published elsewhere⁹.

Light-dependent phosphorylation of rhodopsin in living frogs

PHOSPHORYLATION of rhodopsin has been studied so far only *in vitro*. When suspensions of isolated and purified rod outer segments (ROS) from cattle and frogs have been mixed with γ -³²P-ATP and Mg²⁺, upon illumination ³²P-phosphate has been found to be bound covalently to rhodopsin in a slow dark reaction after bleaching. The activity of the water-

extractable kinase which mediates the phosphate transfer was found to be independent of light, but rhodopsin was not acceptable as a substrate until it had been bleached by light⁴. The slow rate at which phosphorylation occurs (half time 3–5 min (refs 1–4)) suggests that it may be involved in light adaptation of the rods which also seems to be a slow process⁵.

If the phosphorylation reaction plays a role in vision, it should be reversible; rhodopsin should undergo a cycle of phosphorylation and dephosphorylation. This important question, however, could not be clarified by the *in vitro* experiments: in some instances, dephosphorylation could be observed to occur to some extent^{2,3}, but mostly, the phosphorylation seemed to be irreversible^{1,4,8}. If there is capacity for dephosphorylation, it seems to be easily lost in the system of isolated ROS. Therefore the reaction had to be studied in living animals. That protein is phosphorylated in the ROS of living frogs was reported by Hall and Bacharach⁷ as early as 1970, but they were not interested in the light dependency of the effect. My experiments show that phosphorylation and dephosphorylation of rhodopsin are physiological reactions in the photoreceptors of the frog.

³²P-inorganic phosphate, in two portions of about 2 mCi each, was injected into the dorsal lymphatic sac of frogs (*Rana esculenta*, body weight 40–50 g) at an interval of 15 h. Each injection solution contained 20 μ mol of phosphate in 0.3 ml. The frogs were maintained individually in glass jars containing water, at 23°C in the dark. During the full incubation period of 41 h they excreted on the average $7.5 \pm 4\%$ (s. d.) of the total injected ³²P into the water, but

Fig. 2 ³²P bound to rhodopsin as a function of light/dark adaptation of 16 frogs. ●, Dark adapted (D), for 2 d; ○, light adapted (L) for 20 min; ■, light adapted for 20 min and then dark adapted for the times indicated in the abscissa. The seven light-adapted frogs are numbered as 1–7. ----, A theoretical first order decay curve based on a half time of 13 min, starting from the average phosphorylation level of the seven light-adapted frogs. The radioactivity was determined by scintillation counting of gel slices⁴. The amount of rhodopsin was determined from the area of the rhodopsin peak in stained and scanned gels; a calibration curve was obtained with 40 stained and scanned gels containing different amounts of purified cattle rhodopsin of known concentration. The staining and destaining procedure⁹ was carried out in strictly standardised conditions, and it was assumed that cattle and frog rhodopsin both have the same staining properties with Coomassie brilliant blue. The amount of rhodopsin isolated in the ROS was in general about 100 μ g per frog but varied from 150–40 μ g. The ³²P activity was related to the amount of rhodopsin, and to the total ³²P in each frog body at the moment of its death (total injected d.p.m. minus total excreted c.p.m. during the incubation). In a typical light-adapted frog, for example frog No. 2, there were 5,260 d.p.m. of ³²P bound to 146 μ g of rhodopsin, and 11,200 d.p.m. bound to phospholipid. 7×10^9 d.p.m. had been injected into the frog, 7% of which it had excreted during the incubation. Thus the value plotted on the ordinate is $5,260/146 \times (7 - 0.5) \times 10^9$ d.p.m./ μ g \times d.p.m. = 5.5×10^{-9} μ g⁻¹.

Fig. 1 Electrophoresis of ROS preparations obtained from four different frogs, on gels (length 11 cm) containing 5.8% polyacrylamide and 1% sodium dodecylsulphate (SDS) (ref. 9). To isolate the ROS, both retinas of each frog were shaken vigorously, using a Heidolph Reax I mixer, for 60 s in 2 ml of 45% sucrose solution containing 5 mM Tris-acetate (pH 7.3), 65 mM NaCl, and 1 mM MgCl₂. Differential centrifugation was carried out according to McConnell⁸. The final ROS pellet was solubilised with 100 μ l of 2% SDS containing 2% 2-mercaptoethanol, for 20 min at 45°C. Insoluble material derived from pigment epithelium was removed by centrifugation. L₁, Light-adapted frog, with retinas and ROS prepared in white light; L₂, light adapted with retinas and ROS prepared in dim red light; D, dark adapted for 2 d; LD, light adapted and then dark adapted for 75 min. The three light-adapted frogs were exposed for 20 min to diffuse white light of 450 lx. On the left side, photographs of gels stained with Coomassie brilliant blue are shown; the corresponding autoradiographs, exposed for 4 d on X-ray film, are shown on the right. The ink mark near the lower end of the stained gels indicates the position of the marker dye, pyronin Y, which ran to about the same position as the phospholipids. The autoradiographed gels contain 2–5 times more ROS material than the stained gels.

this value was as high as 13 and 14% in some frogs and as low as 0.5% in another. Forty to forty-one hours after the first injection, the frogs were subjected to different light/dark conditions: some were left in the dark, others were light adapted, and others first light and then dark adapted. Light adaptation was accomplished in all cases by exposing the frogs for 20 min to white diffuse light (450 lx) from a fluorescent lamp. At the end of the light/dark treatment (41 h after the first injection) the frogs were killed and the retinas were dissected in dim red light. The two retinas of a frog contained on the average 10^6 decompositions per minute (d.p.m.) of ³²P. The ROS were shaken off and purified by a modification of McConnell's procedure⁸ (Fig. 1). To minimise enzymatic reactions during the preparation, all operations were done at 0°C as fast as possible and, unless otherwise stated, in dim red light. The elapsed time between killing a frog and solubilising its ROS was 35–40 min.

The solubilised ROS were separated by SDS gel electrophoresis. Results obtained from four different frogs are shown in Fig. 1. The purity of the ROS preparation is indicated by the relatively large rhodopsin band in the stained gels shown at the left, demonstrating that rhodopsin is the predominant protein¹⁰. The two radioactive bands in the autoradiographed gels (Fig. 1, right)

correspond to ^{32}P -rhodopsin (middle of gells) and ^{32}P -phospholipids (lower end). The phospholipid nature of the lower band was demonstrated by extracting the ROS with chloroform/methanol¹¹ followed by thin layer chromatographic analysis of the extract. This phospholipid band was found in all frogs, independent of their light/dark treatment, and represents freshly synthesised phospholipids which were incorporated into the ROS during the 41 h incubation period. Inorganic phosphate was also found when the gels were electrophoresed for shorter times, but normally most of the phosphate was eluted into the anode buffer because of its faster mobility, compared to the phospholipids.

The rhodopsin obtained from the light-adapted frogs was phosphorylated (Fig. 1, L_1 and L_2), but that from the dark-adapted frogs was not. One of the dark-adapted frogs (Fig. 1, D) was dark-adapted for 2 d before being killed and the other (LD) was dark-adapted for only 75 min following an illumination period of 20 min; ^{32}P was not bound to the rhodopsin of either animal. This indicates that rhodopsin was phosphorylated when the frogs were exposed to light and dephosphorylated during dark adaptation.

Quantitative analyses indicate that phosphorylation of rhodopsin in the light adapted frogs was about 20 times that in the completely dark-adapted frogs (Fig. 2). The average ^{32}P bound to the rhodopsin of the seven light-adapted frogs was 5.1×10^{-8} per μg of rhodopsin (s. d.: $\pm 1.1 \times 10^{-9} \mu\text{g}^{-1}$), compared to $0.25 \times 10^{-9} \mu\text{g}^{-1}$ in completely dark-adapted frogs. No significant difference in the final yield of ^{32}P -rhodopsin could be observed between retinas and ROS from light-adapted frogs prepared in white light (Fig. 2, frogs 1, 4, 6, and 7) and those prepared in dim red light (Fig. 2, frogs 2, 3 and 5). This indicates that no significant, light-dependent changes in the phosphorylation level occurred during the 40 min preparation period at 0°C .

In the eight frogs which were dark adapted after a 20 min illumination period, the phosphorylation level of rhodopsin decreased slowly with increasing time in the dark, and after approximately 1 h the dephosphorylation was complete. If the dephosphorylation kinetics were first order, its half time would be about 13 min (Fig. 2, dotted line); but quantitative kinetic analysis is not possible because of animal to animal variations and the small number of animals used.

The slow rate of dephosphorylation shown in Fig. 2 is comparable to published rates of dark adaptation measured by psychophysical^{12,13} and electrophysiological^{14,15} methods. Kohlrausch¹² has shown that complete recovery of psychophysical sensitivity during dark adaptation in the human eye takes about 1 h. Similarly, electrophysiological studies on isolated retinas of frog¹⁴ and *Necturus*¹⁵ show that, following extensive bleaching, recovery of sensitivity occurs within about an hour.

Evidence has increased in the past few years that, besides 'neural' control mechanisms, substantial parts of dark adaptation take place in the photoreceptors themselves¹⁴⁻¹⁷. Rushton¹⁶ has demonstrated by combined psychophysical and spectrophotometric measurements that during slow dark adaptation, recovery of the logarithm of sensitivity occurs exactly in parallel with photopigment regeneration. On the other hand, electrophysiological experiments^{14,17} on isolated retinas in which regeneration of rhodopsin is believed to be negligible, demonstrated that slow recovery of sensitivity by 2-4 decades occurs at the receptor level even though regeneration is minimal. Thus there must be mechanism(s) of slow dark adaptation at the receptor level which are independent of photopigment regeneration. My experiments give evidence of a chemical reaction, namely dephosphorylation of phosphorylated rhodopsin, which takes place in the photoreceptors under the conditions and at about the rate of dark adaptation. This dephosphorylation seems to be independent of photopigment regeneration,

as recent experiments with isolated frog retinas have indicated (H.K., and Bader, unpublished). We have also shown⁴ that the regeneration of rhodopsin *in vitro* is not affected by the binding of phosphate to opsin, nor is the binding affected by regeneration; phosphorylated opsin regenerated with 11-*cis* retinal to form phosphorylated rhodopsin, and gave as good a result as in the nonphosphorylated control experiment, without any loss of phosphate during the regeneration.

The molecular mechanism by which this phosphorylation reaction regulates the sensitivity of the rods remains to be elucidated. As suggested earlier⁴, the phosphate group bound to rhodopsin and/or opsin in the light adapted state could alter the permeability of the membrane in which it is located and thus regulate ion fluxes through adjacent pores. This membrane could be the disk as well as the cell plasma membrane which has also been shown to contain rhodopsin¹⁸. Phosphorylation could also influence the binding of Ca^{2+} to the photoreceptor membranes. It is likely that during dark adaptation the phosphate is cleaved from rhodopsin by the action of a phosphatase.

I thank Professor H. Stieve and my colleagues at the institute for discussions and critical reading of the manuscript, and I thank Miss S. Bader and Miss E. Mavrommati for their technical assistance.

Regulation of arginine catabolism in *Aspergillus nidulans*

In *Aspergillus nidulans*, mutations at more than 20 loci result in increased levels of two arginine catabolic enzymes, arginase and ornithine δ -transaminase (OTase)¹. The large number of genes involved either directly or indirectly in regulation of arginine catabolism makes interpretation of the regulatory mechanism(s) complicated. Some of these genes at least are concerned with catabolite repression rather than with control of specific induction and repression processes². Here we

present evidence that the synthesis of arginase and OTase in *A. nidulans* is regulated in a positive fashion. Interrelations between the gene responsible for positive control and several other genes involved in the regulation of these enzymes were established. This enabled us to propose a model of the regulatory mechanism involving interaction between a specific positive and a nonspecific negative mode of regulation and providing a possible explanation of ammonium repression.

In *A. nidulans* arginine can serve as a source of proline both in the wild-type strain and in proline mutants blocked in the first two steps of the main pathway of proline synthesis. Use of arginine for proline synthesis depends on the presence and on the inducibility of arginine catabolic enzymes, arginase and OTase. Mutants with derepressed arginase and OTase were obtained in *A. nidulans* as suppressors of proline mutations^{3,4}. A mutant designated *arcA*^d 47 (former symbol *suG* 47 *pro*) (ref. 2) shows approximately 10-fold higher levels of both enzymes compared with those in the wild-type strain (Table 1). In heterokaryons and diploids *arcA*^d 47 is semidominant over the wild-type allele. By means of the haploidisation technique⁵ the *arcA* locus was assigned to linkage group VIII. The *arcA* locus is not linked to the structural genes for arginase and OTase.

We selected for mutants unable to use arginine as a source of proline and isolated mutants in the arginase and OTase structural genes, mutants defective in arginine transport (unpublished data), mutants hypersensitive to catabolite repression² and mutants designated by the *arcA*^r symbol. In *arcA*^r1 mutant the uninduced levels of arginase and OTase are the same as in the wild type, but neither enzyme is inducible by exogenous arginine. On the basis of recombination tests the *arcA*^r and *arcA*^d mutations seemed likely to be located within the same gene as no *arcA*⁺ recombinants were found among 600 progeny of the cross *arcA*^r × *arcA*^d. This assumption was strengthened by the results of studies on the ultraviolet-induced revertants of the *arcA*^r1 mutant. One of the revertants was found to exhibit all properties of the *arcA*^d47 mutant. By crossing this revertant to the wild type and *arcA*^d47 strains it was established that the reversion was due to mutation in or very close to the *arcA* locus. The *arcA*^r1 mutation is recessive to the *arcA*^d47 and *arcA*⁺ alleles.

The simplest interpretation of the properties of the *arcA*^r and *arcA*^d mutants is that the *arcA* gene specifies the product (inducer) which is necessary for expression of the arginase and OTase structural genes. In the wild type the inducer requires activation by the coinducer, arginine, whereas in the *arcA*^d47 mutant the inducer is active even in the absence of arginine. In the *arcA*^r1 mutant the inducer is inactive or it is not produced.

Table 1 Arginase and OTase activities in various mutants

No. Mutant*	Enzyme activity†			
	Arginase MM	OTase MM	MM + arg	MM + arg + NH ₄
(1) Wild type	0.20	7	110	30
(2) <i>arcA</i> ^r 1	0.20	5	5	5
(3) <i>arcA</i> ^d 47	4.0	50	105	95
(4) <i>suA25pro</i>	2.0	70	130	120
(5) <i>suD25pro</i>	2.0	75	140	130
(6) <i>arcA</i> ^r 1 <i>suA25pro</i>	0.20	10	22	—
(7) <i>arcA</i> ^r 1 <i>suD25pro</i>	0.15	6	7	—
(8) <i>arcA</i> ^d 47 <i>suA25pro</i>	4.0	180	190	—
(9) <i>arcA</i> ^d 47 <i>suD25pro</i>	4.0	200	200	—

Mycelia for enzyme assays were grown on standard minimal medium (MM) (10 g glucose l⁻¹ as carbon source, 10 mM sodium nitrate as nitrogen source) and transferred when necessary to media containing 5 mM arginine or 5 mM arginine and 5 mM ammonium tartrate for 6h.

* Genotypes of mutants: nos 1–4—*proA6 paba9 biA1*; nos 5, 7, 9—*proA6 adF9 y; phenA2*; nos 6, 8—*proA6 paba9 biA1; phenA2*.

† Units of arginase and OTase activity are that amount of enzyme which forms 1 μmol of urea and 1 μmol of glutamic γ-semialdehyde per min per mg protein respectively.

Arginase and OTase synthesis in *A. nidulans* is subject to both glucose and nitrogen catabolite repression. The mechanism of catabolite repression in fungi is not yet fully understood, but ammonium seems to be involved in nitrogen catabolite repression.⁶ One of the effects of ammonium is the prevention of induction of arginase and OTase by arginine⁶. Similar effects of ammonium on arginase and OTase induction were observed in yeasts^{7,8} and on induction of several other catabolic enzymes in *A. nidulans* and *Neurospora crassa*⁹.

The arginase and OTase levels in the *arcA*^d47 mutant are not fully derepressed and the synthesis of both enzymes can still be induced by exogenous arginine (data for OTase are given in Table 1). In contrast to the wild type, the presence of ammonium in the culture medium does not prevent induction of arginase and OTase in the *arcA*^d47 mutant. Assuming that the function of the *arcA* gene is interpreted correctly, it can be concluded that ammonium interferes with the process of activation of the *arcA* gene product (inducer) by arginine. As a result of the *arcA*^d47 mutation the inducer is able to function in the absence of arginine (although it retains some affinity for arginine) and at the same time becomes insensitive to the effects of ammonium.

Apart from the *arcA*^d47 mutation, mutations in six *supro* loci (designated respectively *A*, *D*, *E*, *H*, *J* and *L*) result in derepression of arginase and OTase to the level exceeding

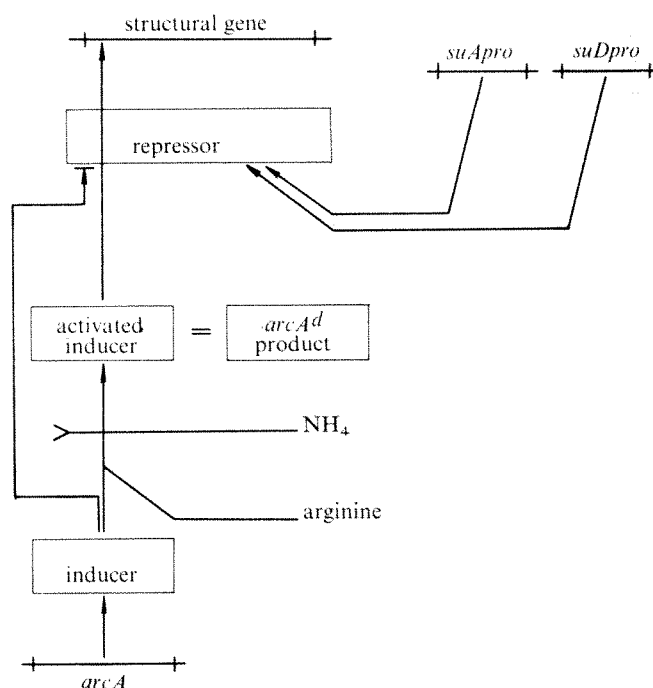

Fig. 1 Regulation of arginine catabolism.

approximately 10-fold the basal level of these enzymes observed in the wild-type strain¹. The levels of both enzymes are not repressed when *supro* mutants are grown in the presence of ammonium. All 25 mutations at these loci which we have studied are recessive and none of the loci is closely linked to any other or to the loci of the arginase and OTase structural genes. Two mutants, *suA25pro* and *suD25pro* were chosen and crossed to the *arcA*^d47 and *arcA*^r1 strains. The appropriate double mutants were selected from the progeny of these crosses and assayed for arginase and OTase activity. The results given in Table 1 can be summarised as follows: (1) The effects of *suA25pro* and *arcA*^d47 mutations are additive, as are the effects of *suD25pro* and *arcA*^d47. The level of both enzymes in double mutants corresponds to their maximal level observed in the wild type grown in the presence of arginine. (2) The *arcA*^r1 mutation cancels the effects of both *suA25pro* and *suD25pro* mutations and makes arginase and OTase

noninducible by arginine in *suA* and *suD* strains. The *arcA*¹ mutation is thus fully epistatic to the two suppressor mutations studied.

It can be concluded that the *suApro* and *suDpro* genes participate in the formation of a repressor which maintains the arginase and OTase synthesis at the low level observed in the wild-type strain grown in the absence of arginine. The function of the repressor is abolished by the activated inducer specified by the *arcA* gene. Activation of the inducer is necessary only to overcome the effects of repression exerted by the products of *suApro*, *suDpro* and possibly other *supro* genes: when the repressor is not active as in *suA25pro* and *suD25pro* mutants, the synthesis of arginase and OTase is derepressed despite the absence of arginine. On the other hand, inactivation of repressor alone is not sufficient to cause derepression of enzyme synthesis. Low levels of arginase and OTase in *arcA*¹ *suA25pro* and in *arcA*¹ *suD25pro* double mutants indicate that the presence of the normal product of the *arcA* gene is obligatory for derepression to occur. All above considerations are summarised in Fig. 1.

We have no information concerning the nature of the *suApro* and *suDpro* gene products. Thus we do not claim that these genes participate in formation of repressor equivalent to that of the *Escherichia coli* lactose system. This would be premature, especially knowing that in its formation not only *suApro* and *suDpro* but probably also four other genes are involved. Moreover, there is some information that mutations in these genes, in addition to controlling arginine catabolism, affect some other systems; for example they cause derepression of nitrate reductase synthesis (unpublished results). It was also found that the *suD19pro* mutation affects the synthesis of ornithine transcarbamylase¹⁰ and cancels certain effects of mutations in the *areA* gene which controls use of a variety of nitrogen sources⁹. It seems therefore that if *suDpro* and other genes of this group are responsible for formation of repressor of some kind, this repressor is highly nonspecific.

As pointed out by Gross¹¹, in fungi the positive rather than negative control of gene expression is the rule. The only exception so far was found by Wiame and his coworkers⁸ who proved the existence of operator genes in the arginine system in yeasts. The universality of positive regulation suggests that in fungi general regulatory mechanisms (those which control expression of genes concerned with many different enzymatic systems) can operate at the level of activation of inducers specific for structural genes of a single system. Such an interpretation was used in this paper to explain the effects of ammonium on the synthesis of arginine catabolic enzymes. We do not postulate that this is the only way in which ammonium affects the synthesis of catabolic enzymes. For example, ammonium also seems to participate in the mechanism responsible for maintaining the basal level of several enzymes^{2,6,12,13}. It is also probable that the inhibitory effect of ammonium upon induction of catabolic enzymes is mediated by the product(s) of particular gene(s), possibly including the *areA* gene which has recently been studied in several laboratories (see ref. 9).

Inhibition of allergic reactions by a novel phenanthroline ICI 74,917

FOR 4 yr we have been investigating the biological properties of a series of kynurenic acids (I) and bridged analogues (II), related to the chromone carboxylic acids, of which disodium cromoglycate (III) is an example. Some of the quinolone acids I and II were found to be as effective as disodium

cromoglycate in inhibiting passive cutaneous anaphylaxis (PCA) in rats^{1,2}. Compounds of much greater activity in PCA were however discovered among a series of tricyclic quinolone acids, the 2,8-dicarboxy-4,10-dioxo-1,4,7,10-tetrahydrophenanthrolines (IV)³. Here we describe the properties of one of the more active of these compounds, ICI 74,917 (IV, R = *n*-butyl). It can be prepared by the reaction of 1,3-diamino-4-*n*-butyl benzene with oxaloacetic ester and thermal cyclisation of the bis-anil to the phenanthroline-2,8

dicarboxylate which is then hydrolysed to ICI 74,917. It melts at 300° C (decomposition) and is insoluble in most organic solvents although its alkali metal salts are soluble in water. It may exist in tautomeric forms other than that indicated.

Administered intravenously as the sodium salt, at the time of antigenic challenge, ICI 74,917 inhibited PCA provoked by reaginic (IgE-like) antibody prepared according to Mota⁴ against egg albumin or according to Ogilvie⁵ against the nematode parasite *Nippostrongylus brasiliensis*. A comparison of the ID₅₀ (the dose required to produce a 50% inhibition of PCA) of each compound revealed that ICI 74,917 was some 300 times more active than disodium cromoglycate (Table 1).

In vitro, ICI 74,917 was not an antagonist of histamine or 5-hydroxytryptamine. When administered intravenously, it did not inhibit blueing reactions provoked in the normal rat by intradermal injections of histamine, 5-hydroxytryptamine or Compound 48/80 but PCA reactions induced in this species by heat-stable (IgG) homocytotropic and heterologous (Guinea pig and rabbit) antibodies were significantly and consistently inhibited to a slight extent (30%).

It seemed possible, on the basis of these findings that ICI 74,917 might prevent the release of inflammatory medi-

ators from mast cells which follows interaction of antibody and antigen. This hypothesis was supported by the demonstration that ICI 74,917, when present at antigenic challenge at concentrations between 10^{-8} M and 10^{-6} M, reduced significantly the amount of histamine liberated from rat peritoneal mast cells sensitised *in vitro* with reaginic antibody.

Fig. 1 Inhibition of allergic bronchospasm in the guinea pig by ICI 74,917. Groups of 10 animals were passively sensitised with guinea pig anti-egg albumin serum and challenged 18 h later with antigen (1 mg), and with saline or varying doses of ICI 74,917 in saline. Bronchospasm was assessed by the Konzett-Rössler technique as modified by Davies and Johnston⁷. Results are expressed as % inhibition of bronchospasm (\pm s.e.) 4 min after antigenic challenge compared with sensitised, control animals given antigen and saline alone.

ICI 74,917 also possesses anti-allergic activity in other species. In the mouse, PCA induced by a reaginic antibody prepared according to Mota⁶ was inhibited, but the amount (0.5–2.5 mg kg⁻¹ intravenously (i.v.)) of compound required to achieve a regular dose dependent inhibition (27 to 67%) was higher than that required in the rat. Although there was no evidence of bronchodilator activity in the guinea pig, the compound, administered intravenously, conferred partial protection against systemic anaphylaxis and at doses comparable to those necessary to inhibit PCA in the rat, reduced in a dose-dependent manner allergic bronchospasm (Fig. 1) in guinea pigs passively sensitised with an homologous nonreaginic antibody prepared according to Davies *et al.*⁷. On the other hand, ICI 74,917, even at relatively high doses, did not inhibit PCA induced with the same antibody, suggesting in this species, some tissue specificity for the compound. Disodium cromoglycate showed no activity in these models in the mouse or guinea pig at doses up to 50 mg kg⁻¹ i.v..

Table 1 A comparison of ICI 74,917 and disodium cromoglycate on reagin-mediated PCA

Compound	Antigen-antibody system	ID ₅₀ (mg kg ⁻¹ i.v. \pm 95% confidence limits)	Relative potency (\pm 95% confidence limits)
Disodium cromoglycate	Egg albumin	2.8 \pm 0.2	1.0
	<i>N. brasiliensis</i>	3.4 \pm 0.2	1.0
ICI 74,917	Egg albumin	0.009 \pm 0.0005	323 \pm 30
	<i>N. brasiliensis</i>	0.01 \pm 0.0006	308 \pm 24

These studies have shown that ICI 74,917 exhibits anti-allergic properties additional to those possessed by disodium cromoglycate in that it is effective in laboratory species other than the rat. ICI 74,917 may therefore be of value in the treatment of allergic conditions in man.

Regulation of clonal development of immune responding cells by antibody of maternal origin

PASSIVELY administered antibody can regulate homologous antibody production in adult animals but the mechanisms are not completely understood¹. Maternal antibody transmitted to the foetus also has such an effect². This effect is usually transient and reversible; animals regain the ability to respond to antigen after passively administered antibody is removed^{3,4}. Adoptively transferred spleen cells from donor animals previously exposed to antibody are also able to respond normally⁵. Mature B and T cells seem also not to be affected by exposure to passively administered antibody^{6,7}.

It is not known if passively administered antibody has any influence upon the clonal development of immune cells. So, we studied the effect of the administration of specific maternal antibody on the ability of progeny to mount antibodies against the appropriate antigen. This was undertaken because in certain species the progeny are exposed to maternal antibody *in utero* during the course of foetal clonal development of immune cells⁸. We found that clonal cells responding to at least some antigens may proliferate as a consequence of being exposed to homologous antibody during foetal or neonatal life.

Female C₃H/He mice were immunised several times with sheep red blood cells (SRBC) before mating. The progeny,

Table 1 Plaque-forming ability of normal and SRBC mice to SRBC in adoptive transfer experiments

Donor spleen	No. of mice	Average PFC in recipient spleens per 10 ⁶ donor spleen cells \pm s.e.
Normal mice	10	538 \pm 344
SRBC mice*	11	506 \pm 291

Spleen cells of 3-week-old normal or SRBC mice were transferred to syngeneic normal X-irradiated mice. Recipient mice were immunised intravenously with 4×10^8 SRBC 8 d before being assayed for their splenic PFC response. PFC to SRBC was assayed as described⁹. PFC in recipients that received either no antigen or no donor cells were negligible.

* Progeny mice whose mother had received SRBC immunisation several times before mating.

SRBC mice, were bled at 3 weeks of age and spleen cells were transferred to normal syngeneic X-irradiated mice. The numbers of plaque-forming cells (PFC) to SRBC amongst the recipient spleen cells were assayed 8 d after antigen injection. Spleen cells from progeny of nonimmune mothers were treated and tested in the same way as a control.

It was found that the number of PFC to SRBC amongst the spleen cells of recipient mice were similar whether recipients received donor spleen cells from normal or SRBC mice (Table 1). At the time of cell transfer, SRBC mice had a high titre of anti-SRBC antibody in their serum which should have been sufficient to suppress active production of antibody to SRBC. These results suggest that maternal antibody against SRBC does not affect the foetal development of specific immune responding cells.

When similar experiments were done using DNA as the test antigen different results were obtained. Female C₃H/He mice were immunised several times with denatured calf thymus DNA to attain high titres of anti-DNA antibody. The progeny, DNA mice, from immunised mothers were then treated in the same way as SRBC mice substituting DNA as the specific antigen. The numbers of PFC to calf thymus DNA amongst spleen cells from recipients who received spleen cells from DNA mice were three to four times those of the controls (Table 2). Although the number

Table 2 Plaque-forming ability of normal and DNA mice to DNA in adoptive transfer experiments

Donor spleen	No. of mice	Average PFC in recipient spleens per 10 ⁶ donor spleen cells \pm s.e.	
		Exp. 1	Exp. 2
Normal mice	3	40.1 \pm 2.7	41.2 \pm 12.9
DNA mice*	3	117.9 \pm 19.0	161.7 \pm 37.7

Experimental procedures are essentially the same as those in Table 1. Heat-denatured calf thymus DNA was conjugated with equal amounts of methylated bovine serum albumin and emulsified with complete Freund's adjuvant. Recipient mice were challenged to a single injection of antigen (100 μ g as DNA) subcutaneously. Anti-DNA PFC were assayed using SRBC coupled with DNA by chromium chloride¹¹. PFC in recipients that received either no antigen or no donor cells were negligible.

* Progeny mice whose mother had received DNA immunisation several times before mating.

of animals studied and the number of antibody-producing cells were small, the differences were significant.

Another experiment also showed the increased PFC response to DNA in DNA mice. Maternal anti-DNA antibody in DNA-mice became undetectable by 6 weeks of age. Normal and DNA mice were challenged with DNA at this age and the PFC response in their spleens was compared 4 d after DNA injection. As shown in Table 3, PFC in the spleen cells of DNA mice were much more than those of control mice.

The enhanced ability of DNA mice to respond to DNA is probably mediated by passively transferred maternal antibody, although the possible involvement of other factors such as passively transferred antigen, carrier protein, and adjuvant were not considered in these experiments. The observed effect of anti-DNA antibody (presumably maternal) in the progeny seems to be different from the suppressive effect of antibody on active antibody production in adult mice, as the enhanced ability to respond to DNA in DNA mice remained even after removal of antibody.

Increased PFC response to DNA in DNA mice may be interpreted as a result of maternal anti-DNA antibody influencing the clonal development of DNA-specific immune responding cells in the progeny. We do not know to what extent these observed effects of maternal antibody are

Table 3 PFC response in normal and DNA mice challenged to DNA

Group	No. of mice	Average PFC per spleen \pm s.e.
Normal mice	7	1,644 \pm 750
DNA mice	6	4,642 \pm 2,111

Six-week-old normal and DNA mice were challenged to a single injection of DNA and were assayed for their splenic PFC response 4 d after antigen injection.

general. Antigen selectivity clearly exists. DNA is a weak antigen, probably because of its self-antigen nature¹⁰. The clonal development of immune responding cells to DNA may be suppressed during ontogeny of the immune systems, and this may in some way be modified by maternal anti-DNA antibodies. Antigen selectivity and the mechanism of this phenomenon need further clarification. A detailed paper will be published separately.

Activation of suppressor T cells by tumour cells and specific antibody

IMMUNOSUPPRESSION by passively administered antibody has long been known (see ref. 1 for review) and as antibody can cause enhancement of tumour growth^{2,3}, particular attention has been paid to the role of antibody-mediated immunosuppression in tumour immunology. Hellstrom *et al.* have emphasised that blocking factors, most likely antigen-antibody complexes⁴, suppress cell-mediated immunity and thus play a major part in the progression of tumour growth⁵. Such blocking factors may be an important factor in the induction and/or maintenance of some forms of immunological tolerance⁶⁻⁸. But the mechanism remains obscure.

Some thymus-derived lymphocytes (T cells) may suppress

the immune response of other cells^{9,10}. These suppressor T cells¹¹, like antigen-antibody complexes, may play an important part in the induction of some forms of tolerance^{12,13}, and antigen-antibody complexes may exert their immunosuppressive effects indirectly by preferential activation of suppressor T cells. Since the effective cell-mediated immune response to tumours usually requires the presence of T cells, it is difficult to demonstrate an additional suppressor population of T cells by such manoeuvres as thymus deprivation, which may deplete effector as well as suppressor cells.

Previous studies have shown that hyperimmune isoantibody to leukaemia L-1210 can 'centrally' inhibit the development of spleen cell-mediated immunity in C57BL/6 mice¹⁴. Antibody was also shown to inhibit the development of macrophage-mediated immunity¹⁵. Mice treated with antibody lacked the enlarged vacuolated 'activated' macrophages which are usually observed in these mice 10 d after challenge with tumour. The peritoneal cells of mice pre-treated with antibody before inoculation with L-1210 were small, lacked stainable acid phosphatase granules, and showed no attached or engulfed tumour cells. Moreover, the addition of proved cytophilic antibody to L-1210 cells. The monocytes could, however, form rosettes with sheep erythrocytes¹⁵ or EL-4 leukaemia cells¹⁶ in the presence of specific cytophilic antibody. The suppression was long lived, lasting 14-18 d, and requiring specific antigen as well as antibody to be produced.

Since the assay for this macrophage function does not require the presence of T cells, we used it to investigate whether suppressor T cells are involved in passive enhancement of tumour growth. Our results suggest they do, since thymus deprivation completely eliminates the suppressive effects of passive antibody, as judged by the ability of macrophages to bind specific tumour cells in the presence of cytophilic antibody.

C57BL/6 male mice from Jackson Laboratories, Bar Harbor, Maine, were thymectomised when 7 weeks old or sham thymectomised. One week later all mice were given 850 rad of X irradiation from a Siemens stabilipan 250 kV source, at a dose rate of 85 rad min⁻¹. On the same day 5×10^6 bone marrow cells from 7-8-week-old syngeneic mice were inoculated into the tail vein.

Two experiments were performed; one 5 weeks after irradiation and the other after 13 weeks. The results of the two separate experiments were similar and the pooled results are given in Table 1. A single dose of 0.4 ml of hyperimmune antibody raised in C57BL/6 mice by multiple immunisations with 5×10^6 L-1210 cells was given intraperitoneally (i.p.) 1 d before tumour. Mice were then challenged i.p. with either 5×10^6 live L-1210 cells or 25×10^6 or 50×10^6 L-1210 cells, killed by previous treatment with mitomycin C (2 mg per 80×10^6 tumour cells at 37° C for 60 min).

Cytophilic antibody (0.3 ml) was injected with 2.5×10^6 L-1210 cells i.p. into mice 10 d later, 5 h before killing.

Fig. 1 *a*, Representative field from a 3+ positive slide. Thirteen macrophage cells surround three tumour cells in a clump. *b*, Representative field from a negative slide. Three macrophages without any attached tumour cells are present. Three tumour cells are also present. The dark cell in the middle is unidentifiable.

After killing the peritoneal cavity was lavaged with 6 ml of Fischer's medium. The lavage fluid was centrifuged at 1,000 r.p.m. for 6 min and the cell pellet was gently re-suspended. Covered wet-droplet preparations on a glass slide were coded and then examined 'blind' using a phase contrast microscope. Previous studies have shown that the assay can be done entirely *in vitro* and gives similar results. Results were given an arbitrary 'score' of 0 to 4+ after recording the percentage of macrophages with attached tumour cells and the number of tumour cells that attached to each macrophage. The appearance of the tumour cells and the macrophages (size, presence of refractile granules,

degree of vacuolation and the presence or absence of clumping were also recorded. A score of 0=less than 10% of peritoneal macrophages with attached tumour cells; 1+ = 10–30%; 2+ = 30–50%; 3+ = 50–75%; and 4+ = 75–100% with attached tumour cells.

At least two slide preparations were read for each experimental animal. The mean and standard deviation of the arbitrary scores were calculated for ease of comparison.

Pretreating mice with isoantibody without also giving tumour has no effect on the attachment of macrophages to tumour cells¹⁵. Also, the peritoneal macrophages of normal mice not given isoantibody and inoculated with tumour 10 d previously, bind the tumour extensively whether or not additional cytophilic antibody is given¹⁵. These controls were not repeated in the present studies.

The results (Table 1) show that more than 30% of the macrophages from sham-thymectomised, lethally-irradiated, bone-marrow-reconstituted mice which were otherwise untreated attached L-1210 cells (about 3–5 cells per macrophage) (Fig. 1a) in the presence of cytophilic antibody. If these mice were treated with viable or mitomycin C-killed tumour cells plus isoantibody 10 d before assay, less than 10% of the macrophages attached tumour cells (Fig. 1b). Significantly, pretreatment with isoantibody and L-1210 did not alter the capacity to attach L-1210 cells in the thymus-deprived mice which attached tumour cells in a way indistinguishable from those of the sham-thymectomised untreated ('normal') animals.

These data clearly demonstrate the thymus dependence of the ability of antibody and tumour cells, perhaps acting as complexes, to suppress the binding of tumour cells to macrophages in the presence of cytophilic antibody.

The mechanism by which the T cells exerted their suppressive effect on macrophages is not clear. Others have shown that lymphocytes can make factors which specifically arm macrophages¹⁷. Perhaps they can also make specific factors which act to disarm macrophages by serving as receptors which transmit an inactivating signal when triggered by antigen. Alternatively, the arming factors in excess may act in an inhibitory fashion. Whatever the mechanism, the results clearly show that at least one aspect of antibody-induced immunosuppression is indirectly mediated through T cells. Another form of T-cell dependent antibody-mediated suppression is that produced by anti-allotype antibody¹⁸. Previous work has shown that T cells can suppress the immune functions of other T cells and B cells^{9–12}. Macrophages must now be added to the list of cells affected by suppressor T-cell activity. The precise significance of inhibition of macrophage-mediated immunity in the enhancement phenomenon remains to be determined.

The way in which antigen and antibody, perhaps acting as complexes, activate the suppressor T cells is also unclear. One possibility is that the antibody changes the molecular configuration of the antigen. It is well known that the immunogenicity of antigen is highly dependent on the physical state of antigen²⁰ and in so doing, perhaps, change the T cell response to it. The demonstration by Chan and Sinclair that removal of the Fc fragment from antibody reduces its immunosuppressive qualities²¹ suggests another possible mechanism. Some T cells may have receptors for the Fc portion of some antibodies and the attachment of antigen-antibody complexes at this site might cause them to exert a suppressor function.

In any case, our results offer a possible bridge between two recent observations: the thymus dependence of tolerance induction to some antigens^{12,13} and the presence of immunosuppressive antigen-antibody complexes in otherwise tolerant mice^{6–8}. The suppressive complexes may act through the agency of suppressor T cells.

Polyanions and lipopolysaccharide acts on different subpopulations of B cells

WITH respect to maturation stage, function, and cell surface constituents, lymphocytes bearing immunoglobulin on their (B cells) comprise a heterogeneous population. It has been suggested¹ that binding of mitogens to membrane surface constituents triggers the events leading to stimulation of cell mitosis. The various B cell mitogens can be divided into different chemical classes and different types of mitogens presumably react with different membrane surface constituents. According to these assumptions we tested whether various B cell mitogens act on the same or on different subpopulations of B cells.

Two kinds of experiments were performed. First, spleen cells of nude mice (BALB/c nu/nu lacking functioning T cells) were cultured with optimal doses of various B cell mitogens or with a combination of two different mitogens (both added to the cultures in optimal doses). Second, BALB/c mice 8–10 weeks old were thymectomised. One week later the mice were lethally irradiated and injected with syngeneic bone marrow cells (TXBM-mice) as described earlier². Spleen cells derived from TXBM-mice were cultured at various times after irradiation and after injection of bone marrow cells (XBM-procedure) with dextran sulphate (DS), with lipopolysaccharide from *Escherichia coli* O 55: B5 (LPS, Difco) or with phytohaemagglutinin-P (PHA, Difco). The results and the experimental details are given in Tables 1 and 2.

As already reported^{3,4} polyanions, for example DS (molecular weight 5×10^5 , Serva, Heidelberg) and double-stranded

Table 1 Effect of combinations of DS, poly (I), poly (C) and LPS on activation of DNA synthesis in nude spleen cells

Mitogen	Dose (μgml^{-1})	c.p.m. per culture	Stimulation index
—	0	852	1.0
DS	50	14,850	18.0
LPS	50	10,640	12.5
poly (I), poly (C)	200	7,071	8.3
DS + LPS	50 + 50	31,950	37.5
DS + poly (I), poly (C)	50 + 200	9,031	10.6
poly (I), poly (C) + LPS	200 + 50	17,380	20.4

Spleen cells suspensions ($2 \times 10^6 \text{ ml}^{-1}$) in a total volume of 3 ml were cultured in RPMI-1640 medium (Biocult) supplemented with 5% fresh heat inactivated (56°C for 30 min) human serum; 1-glutamine (2 mmol ml^{-1}), penicillin (100 U ml^{-1}) and streptomycin ($100 \mu\text{g ml}^{-1}$). The cultures were incubated in a humidified atmosphere of CO_2 : air, 5 : 95 at 37°C for 48 h. The mitogens were dissolved in sterile saline (LPS boiled for 1 h) and 0.1 ml of each solution added to the cultures. Controls received saline instead of mitogens. Two μCi of tritiated thymidine (specific activity 2 Ci mmol^{-1} , Radiochemical Centre, Amersham) were added for the last 4 h of incubation. The radioactivity in the trichloroacetic acid-insoluble fraction was determined as described earlier². The results are expressed as c.p.m. per culture and as stimulation indices (c.p.m. in mitogen treated culture/c.p.m. in control culture). Each value represents the mean of c.p.m. detected in five individual cultures. Standard deviation was less than 10%.

homopolyribonucleic acids are B cell mitogens. As shown in Table 1, spleen cells gave an additive response to DS and LPS or to poly (I) + poly (C) and LPS, when both types of mitogens were added simultaneously to the cultures. These results indicate that LPS and polyanions probably act on different subpopulations of B cells. Since dose response studies (data not given here) showed that higher doses of polyanions gave a smaller response than the optimal doses used in this study, the decreased response of the cells to two different polyanions when they were given simultaneously may indicate that polyanions acts on the same subpopulation of B cells.

One week after the XBM procedure, spleen cells derived from TXBM mice responded to DS and to PHA but not to LPS. LPS-positive cells are first seen in the spleen 2 weeks after XBM-procedure. According to the kinetic studies (Table 2) we postulate that the B cell population responding to DS represents a less matured B cell population than the LPS-reactive B cells. Both populations, however, seem to belong to cells bearing

Table 2 Kinetics of appearance of DS-, LPS- and PHA-reactive cells in spleen of TXBM mice

Time after week XBM-procedure	Stimulation index		
	DS	LPS	PHA
1	6.4	0.7	2.9
2	15.9	2.1	4.7
5	8.4	28.4	5.3
7	10.2	10.1	5.8

Spleen cells derived from TXBM-BALB/c mice (1–7 week after irradiation and bone marrow injection) were cultured for 48 h and the incorporation of ^3H -thymidine into the DNA was measured. Cultures stimulated by PHA received $2 \mu\text{g}$ PHA per ml medium. For details see Table 1. The results are expressed as stimulation indices. Each value represents the mean of c.p.m. detected in three individual cultures. Standard deviation was less than 10%.

immunoglobulin on their surface since pretreatment of a normal spleen cell population by polyvalent rabbit anti-mouse- γ -globulin serum and complement (data not given here) destroyed the capacity of the cells to respond to both DS and LPS but not to PHA. On the other hand it has been shown³ that DS but not LPS stimulates DNA synthesis in bone marrow cells of mice. Moreover, the stimulation rate of bone marrow cells derived from TXBM mice by DS was significantly enhanced compared with the reactivity of normal bone marrow cells³. These results and the observation that DS stimulates mice fibroblasts *in vitro* (U. Saar and T. D., in preparation) indicate that the mitotic activity of DS is not restricted to lymphoid cells and that DS

may also be useful for studies on cell differentiation in other systems.

Brain-associated tumour antigens demonstrated by immunofluorescence

It has been reported that lymphocytes from patients with cancer react with a basic protein of myelin, suggesting that brain shares antigen(s) with malignant tumours¹. The brain also possesses an antigen in common with the thymus^{2–5}. Using a heterologous anti-brain serum we have investigated the presence of brain-associated antigens in tumour cells and in lymphoid cells.

Anti-rat brain serum was produced in rabbits by three subcutaneous weekly injections of 1 ml of brain homogenate, containing 10 mg nitrogen, in an equal volume of complete Freund's adjuvant⁶; the rabbits were bled 7 d after the third immunisation.

The rat tumours studied were: gliomas and schwannomas induced in the offspring of pregnant DA Agouti rats injected intravenously with ethylnitrosourea ($10 \text{ mg per kg body weight}$)⁶, spontaneous mammary carcinomas in inbred Agouti rats, a squamous cell carcinoma⁷ in inbred Wistar rats, and Walker carcinoma in outbred Hooded Wistar rats. Unfixed frozen sections, impression films and smears of brain, thymus, bone marrow, tumours and normal non-lymphoid tissues were examined by standard immunofluorescence procedures⁸. Cell suspensions from tumours, thymus, spleen and lymph node were made by gentle mechanical teasing in tissue culture medium 199. Liver and kidney cell suspensions were made by perfusion of the organs with 10 ml of calcium- and magnesium-free Hanks balanced salt solution containing 0.05% collagenase and 0.1% hyaluronidase, followed by incubation of the diced tissue in the same enzyme solution at 37°C for 30 min. Peripheral blood leukocytes, largely ($>90\%$) lymphocytes, were separated from heparinised blood by centrifugation in a Hypaque-Ficoll gradient⁹.

Sandwich immunofluorescence staining of cell suspensions and tissue preparations was carried out by procedures described in detail elsewhere^{8,10,11}. The conjugate was fluorescein isothiocyanate-labelled goat anti-rabbit globulin with a protein concentration of 0.8 g per 100 ml and a fluorescein: protein molar ratio of 4.2. Before use, it was absorbed with human liver powder and rat liver homogenate, so that by itself it gave no staining of the various microscopical preparations.

The unabsorbed anti-rat brain serum stained the membrane and cytoplasm of all the rat tissues examined. After absorptions⁸ with rat erythrocyte membranes, liver and lung

homogenates, bone marrow cells from thymectomised irradiated and bone marrow-reconstituted rats, and dilution 1:4, this antiserum stained both the white matter and the cytoplasm of neurones and glia in unfixed frozen sections and impression films of the brain. Neuronal cytoplasm staining was best seen in sections of the cerebellum where there was strong reaction with the granular layer. The antiserum also stained the surface membranes of 100% of thymocytes, 61% of peripheral blood lymphocytes, 32% of spleen cells, 12% of lymph node cells, 12% of normal bone marrow cells and less than 1% of bone marrow cells from thymectomised, irradiated and bone marrow-reconstituted rats. It also stained the cytoplasm of thymocytes in unfixed frozen sections, smears and impression films, but did not stain smears of bone marrow cells. In contrast, the antiserum stained neither the membranes of cell suspensions of liver and kidney, nor unfixed frozen sections of the following normal rat tissues: heart, muscle, liver,

homogenates of mammary carcinoma, glioma or kidney. Tumour cell membrane staining was inhibited by absorption of the antiserum with brain homogenate and cell suspensions of thymus and tumours (glioma or mammary carcinoma) but not by absorption with kidney cell suspensions. Tumour cell cytoplasm staining was inhibited by absorption with homogenates of brain or tumours (glioma or mammary carcinoma) but not by absorption with homogenates of thymus or kidney (Table 1).

The prevention of brain staining only by brain homogenates points to the presence of an organ-specific brain antigen. The staining of the membranes of thymocytes and thymus-derived lymphoid cells and the inhibition of thymocyte membrane staining by brain or thymic absorptions support the findings of others of "brain-associated thymus antigen". Our observations suggest that there is also a cytoplasmic thymic antigen common to brain and thymus. In addition there seem to be at least two brain-associated tumour antigens: the first is shared by brain and the cell membranes of tumour cells and thymocytes, because tumour cell membrane staining by our antiserum is inhibited by absorption with brain homogenate or thymocyte suspension; the second is shared by brain and the cytoplasm of the tumour cells investigated since tumour cytoplasm staining was inhibited only by absorption with homogenate of brain or either of the two tumours used.

We thank Professor R. C. Nairn for advice and criticism, Dr E. P. Guli for identification of the neural tumours, Dr H. A. Ward for reading the manuscript and Margaret Share for technical assistance.

kidney, testis and skin. Moderate to strong membrane and cytoplasm staining in 100% of cells was, however, observed in all the tumours tested: gliomas, schwannomas, mammary carcinomas, squamous cell carcinoma and Walker carcinoma (Fig. 1). In all cases, no staining was observed in the parallel control tests with preimmune serum, absorbed in the same way as the test serum.

The staining of brain sections was inhibited only by serum absorption with brain homogenates. However, thymocyte membrane staining was inhibited by serum absorption with rat brain homogenate or thymocyte cell suspensions but not by cell suspensions of mammary carcinoma, glioma or kidney, and thymocyte cytoplasmic staining by absorption with homogenates of brain and thymus but not by

Susceptibility of xeroderma pigmentosum cells to chromosome breakage by adenovirus type 12

DNA repair-deficient microbial systems have attracted considerable attention because they offer an insight into the genetic control of sensitivity towards mutagens and carcinogens¹. These studies have become highly relevant to man with Cleaver's discovery² that cells of most patients with xeroderma pigmentosum (XP) have a reduced level of DNA repair synthesis following ultraviolet-irradiation or exposure to several chemical carcinogens³⁻⁶. The impaired repair capacity of XP cells seems to result in their greater sensitivity towards the lethal⁶⁻¹⁰ and chromosome-damaging action¹¹⁻¹² of those physical and chemical carcinogens which induce irreparable DNA alterations. On the other hand the behaviour of XP cells does not differ from that of controls when treated with several potent alkylating mutagens and carcinogens^{5,10,12,13}.

To further characterise the response of DNA repair-deficient cells towards carcinogens and mutagens which belong in different categories, we have examined the effect of infectious and impaired human adenovirus type 12 (AD12) on cultured fibroblasts of three unrelated XP patients and three control subjects. AD12 was used because it readily infects cultured human cells, it replicates within the cell nucleus, it has a capacity to induce chromosome breaks in mammalian cells, including humans cells¹⁴⁻¹⁷, and it forms intranuclear inclusion bodies (IB) which can be used to identify virus-producing cells^{15,16,18,19}. Since the repair capacity of the three XP cultures varied, we examined further whether different degrees of repair deficiency give rise to different sensitivities towards the chromosome-damaging effect of infectious and ultraviolet-impaired AD12.

Fig. 1 Effect of ultraviolet irradiation on the capacity of AD12 to form IBs in three XP cell cultures (XP-E, XP-C, XP-K) and control. Samples were taken 48 h after infection. Virus suspensions were spread in a thin layer in a 60 mm Petri dish and irradiated under constant agitation with a Sylvania germicidal lamp (G15T8). At a distance of 7 inch this gave a dose of 30 ergs mm⁻² s⁻¹. Following irradiation the virus preparation was immediately added to the fibroblast cultures. The virus absorption time was 4 h at 37° C. The original nonirradiated AD12 preparation had an input multiplicity of 50 TCD₅₀ per cell. In each sample 2,000 to 2,100 nuclei were screened for the presence of IBs. Two coverslip cultures were used for each sampling point. ○, Controls (average of three nonaffected persons); ●, XP-E; △, XP-C; ■, XP-K.

Cultured fibroblasts were obtained from small skin punch biopsies of three unrelated XP patients and three control persons of comparable age. The stock cultures were kept in 10 cm diameter plates (Falcon plastic) placed in a CO₂ incubator and were fed Eagle's minimum essential medium (MEM) supplemented with 20% foetal calf serum (FCS) and antibiotics. For the experiments monolayers of cells were grown on glass cover slips (20 × 20 mm) which were kept in small plastic plates. The level of DNA repair synthesis, which was estimated by measuring the unscheduled uptake of ³HdR³, was about 21% for XP-E, 32% for XP-C and 56% for XP-K as compared to that found in three control subjects following ultraviolet irradiation. The stock preparations of AD12, prototype strain Huie, contained 10⁷ TCD₅₀ per 0.2 ml as determined by titration in human embryonic kidney cells. The AD12 preparations seemed to be free of PPLO and adeno-associated virus (AAV), as judged by electron-microscopic examination. Cells with replicating virus were identified by the presence of intranuclear inclusion bodies (IB) which are the replication site of adenovirus^{15,16,18,19}. The frequency of IB parallels results obtained on plaque assays^{16,20} and is dependent on the input multiplicity of the virus. IB and chromosome aberrations were analysed on preparations which were pre-treated with citrate solution, fixed with ethanol-acetic acid (3:1) and stained with a 2% solution of aceto-orcein.

The frequency of XP cells which support viral replication was compared with that in control cultures by counting the proportion of fibroblasts containing IB. In samples taken 30, 48, 72 and 96 h after infection with nonirradiated AD12 the frequency of cells containing IB in the three XP cultures examined depended on the ratio of viruses to cells and closely resembled that of controls. But there was a marked difference between XP cells and controls following infection with ultraviolet-irradiated virus. Relatively small doses of ultraviolet-irradiation which did not alter the frequency of IBs in control cultures reduced the capacity of AD12 to replicate and form IBs in the XP cells (Fig. 1). The capacity of ultraviolet-impaired AD12 to form IB was abolished faster in XP cells with a severe repair deficiency than in those with a less affected DNA repair capacity.

There was a slight increase in the frequency of IB-containing XP cells with time after infection with ultraviolet-irradiated (90 to 1,800 ergs mm⁻²) AD12, but even after 96 h their frequency did not reach the level found in cell populations of nonaffected persons. The extent of recovery of the replicative capacity of ultraviolet-impaired AD12 also depends on the degree of repair deficiency of the host cell. For example, ultraviolet doses of more than 1,800 ergs mm⁻² destroyed the capacity of the AD12 to recover its replicative potential in XP-E cells, whereas a slight recovery occurred in the less repair-deficient XP-C and XP-K cells and a restoration of about 60% took place in cells of nonaffected persons.

The extent of AD12-induced chromosome aberration was estimated by counting the number of metaphase plates with at least one chromatid or chromosome break or one chromatid exchange and by calculating the average number of chromosome aberrations per metaphase plate. There was no significant difference between the frequency of XP cells with chromosome aberrations and that of controls when infected with the same numbers of nonirradiated AD12 and sampled 30, 48, 72 or 96 h after infection. But the behaviour of the three XP cell cultures (XP-E, XP-C and XP-K) departed from that of the controls following infection with ultraviolet-irradiated AD12. Virus preparations irradiated with relatively small doses of ultraviolet were less capable of inducing chromatid and chromosome breaks in XP cells during the first two days after infection (Table 1). The frequency of chromosome aberrations was lower in those XP cells which had a severe DNA repair deficiency than in XP cells with a less impaired repair system. This pattern of survival of a viral function, which can be clearly observed in early samples after infection, closely resembles

that of IB formation in XP and normal cells following infection with ultraviolet-irradiated AD12 (Fig. 1).

In the XP cells examined the chromosome damaging action of ultraviolet-irradiated AD12 seemed to become restored at a later stage after infection (Table 1). The severity of chromosome breakage was also greater in samples taken 72 or 96 h after infection. In the 48 h samples chromatid breaks (Fig. 2a) were the major type of aberration, whereas fragmentation of the entire chromosome complement (Fig. 2b), which leads to the formation of micronuclei (Fig. 2c), predominated in the later samples. The IB-forming capacity of AD12 which received a dose of $3,600 \text{ ergs mm}^{-2}$ was either not restored (XP-E and XP-C cells) or showed only a slight recovery (XP-K cells) within the 96 h period.

Fig. 2 Part of a metaphase plate of an XP-E culture infected with ultraviolet-irradiated AD12 (720 ergs mm^{-2}). *a*, Sampled 30 h after infection. Several chromatid and chromosome breaks. *b*, Sampled 96 h after infection. Fragmented chromosome complement. *c*, Part of a cell with multiple micronuclei of an XP-E culture infected with ultraviolet-irradiated AD12 (720 ergs mm^{-2}) and sampled 96 h after infection.

Controls and XP cells seemed to differ in the extent of chromosome damage rather than in the type of chromosome aberrations which followed infection with nonirradiated or ultraviolet-irradiated AD12. Chromosome fragmentation occurs in the examined XP cells as well as in controls (Table 1). Furthermore the nonrandom distribution of chromosome aberrations which was observed in cultured fibroblasts of normal persons¹⁵ and patients with Edward's syndrome¹⁷ also occurred in XP cells following infection with nonirradiated or ultraviolet-irradiated AD12. For example following infection with ultraviolet-irradiated (180 ergs mm^{-2}) AD12 59%, 67%, 58% and 65% of all chromosome aberrations accumulated in chromosome 1 and 17 of XP-E, XP-C, XP-K and controls respectively, although their combined length was just over 10% of the entire chromosome complement. Furthermore most

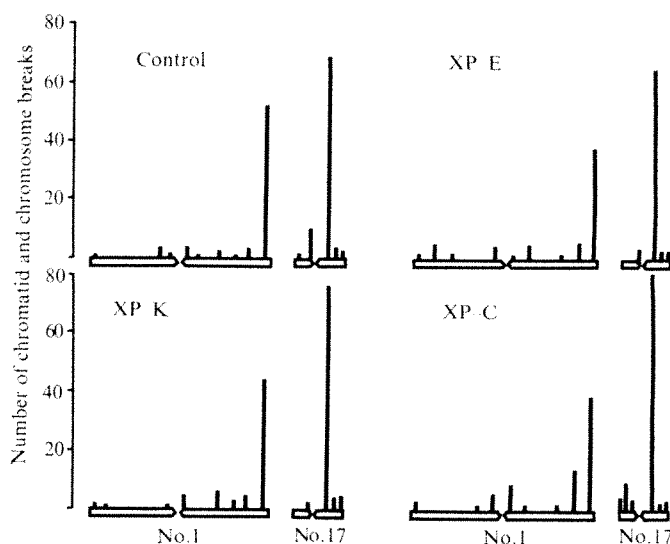

Fig. 3 Distribution of chromatid and chromosome breaks along chromosome 1 and 17 of controls and XP cells (XP-K, XP-E, XP-C) following infection with ultraviolet-irradiated (180 ergs mm^{-2}) AD12. Samples were taken 30 h after infection. For each sample, 60 cells with chromosome aberrations were analysed.

chromatid aberrations were located near the end of chromosome 1 and in the region of the secondary constriction of chromosome 17 (Fig. 3), which agrees with previous observations on cells with a normal¹⁵ and trisomic karyotype¹⁷.

Thus the repair of ultraviolet-irradiated viral genomes, and hence the restoration of replication and chromosome-damaging function, occur at lower levels in XP cells than in host cells with an unimpaired DNA repair system. But even in XP cells ultraviolet-irradiated AD12 induces a relatively high frequency of chromosome aberrations, which are manifested because the impaired virus cannot replicate and thus does not cause cell lysis. The data also show that the chromosome-damaging function is more readily restored than the replicative capacity of the virus. This may be because the first property requires only a part of a functional genome²¹. Furthermore, the degree of survival of these two viral functions depends on the level of DNA repair capacity of the host cells. These results can be compared with the reduced T antigen formation and cell transformation in XP cells infected with ultraviolet-impaired SV40²² and the diminished virus production following infection with ultraviolet-irradiated herpes simplex virus²³. The marked increase in chromosome damage at the third and fourth day after infection with ultraviolet-irradiated AD12 is probably caused by a delayed recovery of viral function, either due to a slow-working excision repair in XP cells or to an exchange

Table 1 Frequency and type of chromosome aberrations of xeroderma pigmentosum cells and controls following infection with ultraviolet-irradiated ($3,600 \text{ ergs mm}^{-2}$) AD12

type of repair between viral genomes in the host cell.

In conjunction with previous reports, this study provides evidence that the sensitivity of XP cells varies towards different physical, chemical and viral carcinogens and mutagens (see ref. 24 for review). Similarly, cells of patients with Fanconi's anaemia have an elevated sensitivity to some but not all mutagenic agents²⁵. Cells of patients afflicted with XP and those with Fanconi's anaemia differ in their response towards the same carcinogens. Such selective sensitivities of certain human groups will make the assignment of carcinogen and mutagen levels that are safe or tolerable to all human beings a difficult, if not impossible, task.

This work was supported by grants from the National Research Council of Canada and the National Cancer Institute of Canada. We thank Drs B. K. Fisher, Calgary, J. Brown, Edmonton and G. B. Goodman, Vancouver for skin biopsies of XP patients.

the flies are old^{11,12}. Russell¹³ reported an increase in induced monosomy in mice by examining the progeny of matings with sex-linked markers. But many aneuploids may be lethal and the dosages used by Russell were large enough to cause loss of chromosomes by breakage. Recent advances in the technique of culturing mouse oocytes *in vitro* (ref. 14, modified by E. P. Evans and C. E. Ford) have made it possible to circumvent these difficulties by examining meiotic chromosomes in second metaphase. The following experiment was designed to examine the effect of low doses of whole-body irradiation on chromosome segregation during first meiotic division in the oocytes of young female mice.

(C3H×ICR/Swiss) F₁ hybrid females, aged 3 and 6 months, were exposed to 10 r., 20 r. and 30 r. whole body γ irradiation from a ¹³⁷Cs source at a focal distance of 51 cm with a rate of 29 r. min⁻¹. The dosage was kept low to minimise chromosome breakage. During exposure, the mice were held in pie-shaped compartments of a round plexiglass container. Equal numbers of control mice were handled in identical fashion but were not irradiated. The mice and their paired controls were killed and their ovaries removed within one week of exposure to radiation. No gonadotrophic hormones were used to stimulate oocyte maturation or superovulation.

The oocytes were teased out of the ovaries and those containing a germinal vesicle were incubated in foetal calf serum for 18–23 h to obtain cells in second metaphase. They were then transferred into a hypotonic solution of 1% sodium citrate for 25 min and those in which the germinal vesicle had disappeared were prepared for chromosomal analysis. A maximum of five oocytes were carefully placed on a microslide, excessive hypotonic solution was removed and a tiny amount of fixative (3:1 methanol:acetic acid) was dropped on the cells and quickly blown dry under the heat of a 25 W bulb. The chromosomes were stained with Giemsa. The slides were coded, before the cells were scored, by three technicians. The number of cells on each slide was recorded so that all cells or remnants of cells were accounted for during the analysis.

Metaphase II chromosomes were clearly analysable in 1,149 irradiated oocytes and 1,054 controls. All identifiable chromosome breaks occurred in the centromeric region and could have resulted from premature separation of the chromatids or rupture during slide preparation. They were slightly more common among the irradiated cells (Table 1), but a significant increase was observed only after exposure to 30 r. There were no acentric fragments and small chromatid breaks, if present, could not be identified because of the characteristic shape of metaphase II chromosomes.

Six of the irradiated oocytes had an extra chromosome, that is, 21 chromosomes (Fig. 1). All other oocytes on the same slides were found and those with analysable metaphase chromosomes were positively identified as having 20 chromosomes. It is unlikely, therefore, that the extra chromosome in these six oocytes had strayed from other cells. Since metaphase II chromosomes cannot be karyotyped, it is not possible to identify the extra chromosome in these cells. No oocytes with an additional chromosome were found among the controls. The difference between irradiated and control is statistically significant ($P=0.02$, Fisher exact test).

Chromosome loss during slide preparation was most probably the cause of our finding oocytes with less than the haploid number of 20 chromosomes. Cells with fewer than 19 chromosomes have not been tabulated. For each oocyte with 21 chromosomes a complementary cell with 19 chromosomes must have been produced to form the polar body. The reverse should also hold true in the absence of preferential segregation of one type of chromosome complement into the polar body, that is, a similar number of polar body cells with 21 chromosomes could have resulted from the abnormal segregation that produced oocytes with 19 chromo-

Radiation-induced nondisjunction in mouse oocytes

BECAUSE chromosomal trisomy is found with relatively high frequencies in congenital malformations and spontaneous abortions in man, the aetiology of abnormal segregation is a pressing problem. One possible factor is exposure of women to diagnostic X rays^{1–8}. Experiments with *Drosophila melanogaster* indicate that nondisjunction can be induced by exposure of females to X rays^{9,10} especially if

Table 1 Frequencies of numerical and structural aberrations in second metaphase oocytes of mice irradiated *in vivo* compared with nonirradiated controls

**Fig. 1** Oocytes in metaphase II with 21 chromosomes from mice irradiated *in vivo*.

somes. Since the latter cannot be distinguished from among the total number of oocytes with chromosome loss, the total frequency of nondisjunctional events can be estimated to be approximately double the number of oocytes with 21 chromosomes, that is, 12, or 1%.

The absence of hypermodal cells among more than 1,000 nonirradiated oocytes in our sample agrees with Russell's conclusion¹³ from phenotypic ratios that spontaneous nondisjunction during first meiotic division in the female mouse is exceedingly rare. On the other hand, examination of metaphase II oocytes of a C₃H inbred strain by Röhrborn¹⁵ gave a spontaneous rate of 2.3% with extra chromatids among 128 metaphase II oocytes obtained from females after mating with vasectomised males and not pretreated with hormones. In a relatively limited sample reported by Yamamoto *et al.*¹⁶, no pure trisomy was observed among foetuses of young mice, irradiated and nonirradiated, but both spontaneous and induced nondisjunction was observed among the progeny of aged mice. These conflicting reports probably reflect strain variations as well as differences in experimental design.

Human epidemiological studies have produced contradictory evidence on the effect of radiation on chromosome segregation. But most with negative results show a slight though insignificant increase in nondisjunction. One notable exception was the report on the effect of the atomic bombs in Japan² but cytogenetic investigations are now beginning to reveal a significant increase in sex chromosome aneuploidies among the children of exposed parents¹⁷. The human situation has emphasised the need for experimental

confirmation. The results of our experiment indicate that nondisjunction can be induced in young female mice by exposure *in vivo* to low doses of radiation.

We thank Drs C. E. Ford and E. P. Evans for the technical procedures used in this experiment and for reviewing our photographs of chromosome spreads. Technical assistance was provided by T. K. Ho and W. S. Tsuchida. This work was supported by a grant from the Medical Research Council of Canada.

Very long stretches of free DNA in chromatin

THE arrangement of histones along the DNA in chromosomes has been studied using digestion of the chromatin with DNase¹⁻⁴ and titration of the chromatin with polylysine^{5,6} or certain dyes^{7,8} as probes. The precision of these probes is limited by the extent to which DNA partially covered with histones will react with the enzymes or titration agents used^{7,8}. Furthermore, it has been noted that histones are redistributed along or between DNA fibres under conditions arising during the normal course of isolation and handling of the chromatin⁹⁻¹². This phenomenon may have strongly influenced the results obtained previously.

Fig. 1 Long stretches of completely free DNA in DNP-F₁. Mice carrying Ehrlich ascites tumour cells were injected intraperitoneally with a mixture of methyl-³H-thymidine and ¹⁴C-lysine to obtain a double-labelled chromatin¹⁰⁻¹². Less than 0.1% of the total ¹⁴C counts were in DNA and 0.1-0.2% of the total ³H counts were in protein. The specific radioactivity of the ³H-DNA in the ¹⁴C, ³H-chromatin was usually 2×10^4 - 3×10^4 c.p.m. μg^{-1} . The ¹⁴C/³H ratio was usually about 0.6.

We have tried to examine directly the distribution of histones in the chromatin under conditions that minimise the redistribution of histones¹⁰⁻¹². Our method is based on the direct detection and quantitation of the free DNA segments by equilibrium centrifugation of formaldehyde-fixed deoxyribonucleoproteins (DNP) in CsCl gradients¹¹⁻¹⁵. The use of highly labelled chromatin enables work at low DNP concentrations thus minimising aggregation of the DNP^{11,12}.

Double-labelled chromatin (³H-DNA, ¹⁴C-protein) was used throughout our work. Briefly, unsheared chromatin was prepared from mouse Ehrlich ascites tumour cells which were simultaneously labelled *in vivo* with methyl-³H-thymidine and L-¹⁴C-lysine^{11,12}. The purified chromatin¹⁰⁻¹² was washed and suspended in 1 mM MgCl₂, 1 mM Na₂HPO₄, pH 7.8 buffer to a final concentration of 20-50 μg DNA ml⁻¹. Purified total yeast tRNA was added to this suspension to a final concentration of 1 mg ml⁻¹ and the mixture was incubated at 0° C for 3-4 h (ref. 10). The swelled gel was solubilised by treatment in a Dounce homogeniser and the resulting soluble ¹⁴C, ³H-DNP lacking histone F1 and most nonhistone proteins (DNP-F₁) was separated from the tRNA-¹⁴C-protein complexes and from the free tRNA by gel chromatography on Sepharose 2B (refs 10-12). No degradation of histones (as monitored by polyacrylamide gel electrophoresis^{10,11}) could be detected for up to 48-64 h at 0-4° C in either the chromatin gel or the soluble unfixed DNP-F₁.

Soluble ¹⁴C, ³H-labelled DNP-F₁ with an average chain length of about 10 kbases (1 kbase \equiv 1000 bases or base pairs) was fixed with formaldehyde and centrifuged to equilibrium in CsCl (Fig. 1). The majority of the DNP is banded at a density of 1.46 g cm⁻³ with a prominent shoulder at higher densities up to the density of the free DNA (1.70 g cm⁻³) (Fig. 1a). Thus, even in the sample containing high molecular weight DNA one could observe a significant fraction of material which contained much less protein than the main component.

When the formaldehyde-fixed DNP-F₁ is sheared to an average chain length of about 0.5 kbase (Fig. 1d) the DNP is banded in two homogenous peaks with a negligible amount of material of intermediate density. One peak has the density of free DNA (1.70 g cm⁻³) and the other has a density of 1.46 g cm⁻³ (Fig. 1d). The first band (1.70) does not contain any ¹⁴C-label (protein). The second band (1.46) is characterised by a nearly constant ¹⁴C/³H ratio throughout the peak area; thus the width of this band is determined almost entirely by diffusion. It should be noted that no protein is removed from the fixed DNP upon shearing in either formaldehyde-free or formaldehyde-containing buffer¹¹⁻¹⁴.

The average length of the stretches of free DNA was estimated from experiments in which the intensity of shearing was varied (Fig. 1). When less intensive shearing was used only a fraction of the free DNA was separated from the DNP-F₁. Under these conditions some of the material is distributed between the densities of the two bands (Fig. 1b and c; compare d). The fraction of the

The ¹⁴C, ³H-DNP-F₁ was obtained as described in the text, then fixed in 1% formalin¹¹⁻¹⁴ and thereafter sheared to the required average chain length by mild or strong sonication or by passage through the water-cooled French press. Appropriate controls have shown that the results depended only on the final average length of DNA obtained but not on the particular method of shearing used. The samples were centrifuged in CsCl at 45,000 r.p.m. for 70-75 h in the SW50.1 rotor (Spinco) at 10° C (refs 11 and 12).

Fig. 2 Free DNA molecules in the sheared chromatin. *a*, Sucrose gradient centrifugation. The ^{14}C , ^3H -chromatin¹⁰⁻¹² was washed in 5 mM TEA-HCl, pH 7.8, then suspended in the same buffer to a final DNP concentration of $10\text{--}20\ \mu\text{g DNA ml}^{-1}$ and thereafter sheared to an average DNA length of about 0.5 kbase by a double passage through the water-cooled French press¹⁰⁻¹². The sheared sample was made 1% in formalin and thereafter was centrifuged through a linear 5–40% (w/v) sucrose gradient in the same buffer (35,000 r.p.m.; 3.5 h at 5°C in the SW40 rotor). *b*, As *a* but before layering on to gradient an equal volume of 0.30 M NaCl, 4 mM MgCl_2 , 5 mM TEA-HCl, pH 7.8 was added to the sheared chromatin. After 15 min at 0°C the sample was fixed in 1% formalin and thereafter centrifuged as above. *c*, CsCl equilibrium pattern of the sheared chromatin fixed in 5 mM TEA-HCl, pH 7.8 (see *a*). *d*, CsCl equilibrium pattern of the sheared chromatin fixed in 0.15 M NaCl, 2 mM MgCl_2 , 5 mM TEA-HCl, pH 7.8 (see *b*). \bullet , ^3H -DNA; \circ , ^{14}C -protein; \blacksquare , $^{14}\text{C}/^3\text{H}$; X, density. Arrows in *a* and *b* indicate the position of a dense sucrose shelf.

To achieve a 90% recovery of the DNP in *d*, CsCl centrifugation was carried out in the presence of 0.5% Sarcosyl NL97. Free DNA was recovered quantitatively either with or without Sarcosyl (data not shown).

material of intermediate density consists of DNA-histone complexes linked to remaining stretches of the free DNA. This material is almost undetectable when shearing is more intensive (Fig. 1*b–d*). The lengths of DNA molecules isolated from CsCl gradients were determined by sucrose gradient centrifugation in the presence of internal sedimentation markers (data not shown). One can estimate that the number average length of stretches of free DNA in the DNP-F1 is ~ 4 kbases. The variability in length of free DNA segments in the DNP-F1 remains unknown. It seems, however, that there are few, if any, segments of free DNA longer than ~ 10 kbases (since no free DNA is present in the unshereed DNP-F1 preparation; Fig. 1*a*) and there are almost no segments of free DNA shorter than 1 kbase (since shearing to ~ 0.5 kbase results in an almost complete separation of free DNA segments; Fig. 1*d*). These estimates would indicate the maximal and minimal values while the actual variability of the chain length of free DNA in the DNP-F1 may be, of course, much lower.

The average length of histone-covered DNA in the DNP-F1 is about four times that of the free DNA (since free DNA constitutes 20–22% of the total DNA; Fig. 1*d* and thus equals about 14–16 kbases. It may be estimated that a stretch of 16 kbases of DNA covered with four histone fractions to a protein/DNA ratio of 1.1 (ref. 14) would be occupied by about 8×10^2 histone molecules (assuming an average molecular weight of 13,500 for the histone). These four histone fractions are nearly uniformly distributed within the histone-covered stretch of DNA, as the fragmentation of DNA to ~ 0.5 kbase (corresponding to ~ 25 bound histone molecules) reveals no heterogeneity in histone distribution within histone-covered 'blocks' (Fig. 1*d*).

It was shown previously, that if the unfolding of chromosomal DNP is carried out in the absence of Mg^{2+} ions all DNA-bound histones may be redistributed¹². This particular type of redistribution is completely blocked in already unfolded DNP preparations. If the unfolding-induced dedistribution of histones is allowed, it leads to a considerable decrease of the average length of free DNA segments in the unfolded, histone F1-depleted DNP¹².

The implications of the above findings will be discussed below (see Fig. 5).

Chromatin which was hydrodynamically sheared in a low (0.005) ionic strength buffer lacking divalent cations, sediments in a sucrose gradient as a single peak with a significant internal heterogeneity (Fig. 2*a*). The same DNP, when fixed with formaldehyde and centrifuged to equilibrium in a CsCl gradient, is banded as a single peak with even higher internal heterogeneity (Fig. 2*c*).

The main result of this part of the work is that addition of approximately physiological concentrations of NaCl and/or MgCl_2 to the sheared, unfixed chromatin preparation results in the appearance of a bimodal distribution of the DNP after centrifugation in either sucrose or CsCl gradient (Fig. 2). For example, after a shift to 0.15 M NaCl, 2 mM MgCl_2 , 5 mM triethanolamine (TEA)-HCl, pH 7.8, a significant (18–19%) proportion of completely free DNA molecules appears in the sheared chromatin (Figs 2*b, d* and 3). The average length of either total or free DNA in the experiment presented in Fig. 2 equals about 0.5 kbase. If the shearing of chromatin is less intensive, producing DNA chains with average length of 2–3 kbases, free DNA molecules are still present in the sheared chromatin after addition of NaCl and/or MgCl_2 but their percentage is decreased to 2–3% of the total DNA (data not shown).

An additional feature of the sedimentation pattern of the sheared chromatin in 0.15 M NaCl, 2 mM MgCl_2 (Fig. 2*b*) is that DNP particles, after liberation of the free DNA, sediment 20–30 times faster than the sheared chromatin before addition of NaCl and/or MgCl_2 (Fig. 2*b*; compare Fig. 2*a*). Electron microscopy has shown that this effect is

Fig. 3 Percentage of free DNA molecules in the sheared chromatin as a function of the ionic strength of solution. Each point was obtained by calculating the percentage of the free DNA in a CsCl equilibrium pattern of the sheared chromatin (Fig. 2c and d) which was preincubated in 5 mM TEA-HCl, pH 7.8 plus stated concentrations of NaCl and MgCl₂.

due to a collapse of the DNP accompanied by some aggregation of the DNP (unpublished data).

Percentage of free DNA molecules obtained from sheared chromatin is increased from zero in 5 mM TEA-HCl, pH 7.8 to 26% in 0.24 M NaCl, 2 mM MgCl₂, 5 mM TEA-HCl, pH 7.8 (Fig. 3). At sufficiently high (0.10–0.25 M) NaCl concentrations Mg²⁺ is not necessary for the appearance of free DNA; the same result could be obtained also with NaCl/Na-EDTA mixtures.

After a shift to 0.15 M NaCl, 2 mM MgCl₂ a small fraction (5–7%) of the DNP was reproducibly found cose-dimenting with free DNA molecules in the upper part of the sucrose gradient (Fig. 2b). This slowly sedimenting DNP banded in CsCl at 1.48–1.50 g cm⁻³ and could thereby be separated from the free DNA (Fig. 2d and unpublished data). The significance and origin of this material remains unclear.

Ehrlich ascites tumour cells labelled in the usual manner (see above) were suspended in 0.15 M NaCl, 2 mM MgCl₂, 5 mM TEA-HCl, pH 7.8 and passed once through a water-cooled French press under a pressure drop of about 1.5 kbar. The preparation was fixed in 1% formalin within a few seconds of shearing and thereafter centrifuged to equilibrium in CsCl gradient (Fig. 4). About 10–12% of the total DNA obtained is banded in the region of free DNA (Fig. 4). Appropriate controls (unpublished) have shown

Fig. 4 Free DNA molecules in homogenate of whole cells. *a*, An aliquot of the ¹⁴C,³H-labelled ascitic fluid was immediately diluted ~200 times into 0.15 M NaCl, 2 mM MgCl₂, 5 mM TEA-HCl, pH 7.8, then sheared to an average DNA length of about 0.5 kbase by a single passage through a water-cooled French press and thereafter fixed in 1% formalin within a few seconds after shearing. The sample was centrifuged to equilibrium in CsCl as described in the legend for Fig. 1. ●, ³H-DNA; ○, ¹⁴C-protein; X, density.

that most if not all free DNA is of nuclear origin. A reproducible, but yet unexplained feature of the CsCl pattern of the whole cell homogenate is the relatively high density of the main DNP peak (1.45 g cm⁻³ compared with 1.41–1.42 g cm⁻³ for purified sheared chromatin; Fig. 2c and d). These data indicate that in homogenates of whole cells under physiological ionic conditions long molecules of the free DNA are present.

At the present time it is unclear whether the very long stretches of completely free DNA discovered in this work have a functional significance with regard to transcription or whether they are structural features of the chromosome irrelevant to transcription. Studies on the renaturation of the free DNA and hybridisation of pre-mRNA to free DNA are in progress and should clarify this question.

Fig. 5 Possible mechanisms of formation of free DNA molecules in the sheared chromatin. *a*, An experimentally observed mode of arrangement of histones other than F1 along unfolded chromosomal DNA (see Fig. 1 and the text). *b*, Generation of free DNA molecules in the sheared chromatin according to an 'asymmetric hairpin' model of DNA packing in a chromomere (see the text). *c*, Alternative model for the generation of free DNA molecules from sheared chromatin. Each DNP particle contains only one DNA molecule (see text for details).

At present we would like to consider another question: if there are only DNP particles in the sheared, soluble chromatin and no free DNA molecules (in the absence of NaCl and/or MgCl₂; see Fig. 2) what is the mechanism of generation of free DNA molecules on shifting to physiological ionic conditions? There are two explanations (Fig. 5b and c). According to the first model shearing of chromatin in a low (~ 0.005) ionic strength buffer lacking divalent cation produces DNP particles which contain two

(or more) noncovalently linked DNA molecules per particle. Such DNP particles are interpreted as fragments of the 'asymmetric hairpin' (Fig. 5b). One branch of the hairpin is thought to contain tightly supercoiled DNP whereas the other branch is in a relatively extended form. Addition of 1–2 mM $MgCl_2$ and/or 0.1–0.2 M NaCl induces separation of the branches, the final result being the liberation of free DNA molecules (which correspond to the extended branch) and of the supercoiled DNP particles (Fig. 5b). The asymmetric hairpin model of DNA packing in the chromatin was suggested to explain the observed distribution of histones other than F1 along unfolded chromosomal DNA (Fig. 5a) and also to explain a particular type of histone redistribution which occurs only at the moment of DNA unfolding in the chromatin but not after it (ref. 12; see also above). Furthermore, it should be noted that the average length of histone-covered plus histone-free DNA stretches (~20 kbases; see Fig. 5a) is comparable with the average length of transcriptional units in higher eukaryotes^{16–17}. Although the asymmetric hairpin model (Fig. 5b) is formally consistent with the present experimental data, an alternative model (Fig. 5c) now seems more likely. According to this model, each DNP particle in the sheared chromatin contains only one DNA molecule. In the presence of 1–2 mM $MgCl_2$ and/or 0.1–0.2 M NaCl, interactions between different DNP particles, for example, during 'dimer' or aggregate formation (Fig. 5c) induce an 'asymmetric' redistribution of proteins between DNP particles in the dimer or in aggregates of higher order. As a result dissociation of such a complex produces one molecule of free DNA and one or a few molecules of DNA associated with increased amount of protein (Fig. 5c). At present a more detailed model is not possible.

The second model (Fig. 5c) is consistent with all results obtained with sheared chromatin (Figs 2 and 3 and unpublished data) including the dependence of the final percentage of free DNA on the ionic strength of solution (Fig. 3). Work is now in progress to distinguish between the two models (Fig. 5b and 5c).

Although the *in vivo* significance of the long free DNA segments in the chromatin is not yet understood, it is clear that the fine structure of chromatin is strongly dependent on the ionic conditions of the medium. One should be careful when attempting to assess the significance of results of earlier studies on chromatic structure, which were carried out mainly at low ionic strength^{16,17}.

We thank V. V. Bakayev and A. A. Bayev, jun. for collaboration at later stages of the work, Dr V. N. Soyfer for providing ultracentrifuge facilities and N. N. Dobbert for technical assistance.

Erratum

In the article 'Relative-distance Machian theories' by J. B. Barbour (*Nature*, **249**, 328; 1974) paragraph 7, line 5 should read:

of particles, and their derivatives $\dot{r}_{ij} = dr_{ij}/d\lambda$ with respect

Equation (1) should read:

$$L = \Psi \Gamma \quad (1)$$

where

$$\Gamma = (\sum_{i < j} m_i m_j r_{ij}^2)^{1/2}, i = 1, \dots, N (\dot{r}_{ij} = dr_{ij}/d\lambda)$$

$$\Psi = \sum_{i < j} m_i m_j / r_{ij}$$

Paragraph 7, penultimate line should read:

pendent of the time parameter (a sum like $(\Psi + \Gamma)d\lambda$ would

Equations (2) and (3) and the intervening explanation should read:

$$L = \Psi [\sum_{i < j} m_i m_j (\dot{x}_i^2 - 2\dot{x}_i \dot{x}_j + \dot{x}_j^2)]^{1/2} \quad (2)$$

and the Euler-Lagrange equations

$$\frac{d}{d\lambda} (\partial L / \partial \dot{x}_i) = \partial L / \partial x_i$$

are

$$\frac{d}{d\lambda} \left\{ \frac{\Psi m_i}{\Gamma} \left[\sum_{j \neq i} m_j (\dot{x}_i - \dot{x}_j) \right] \right\} = \frac{\Gamma \partial \Psi}{\partial x_i}$$

We can now specialise both λ ; taking

$$d\lambda = ds = (\sum_{i < j} m_i m_j dr_{ij}^2)^{1/2}, \text{ i.e. } \Gamma \equiv 1,$$

and the coordinate system, taking it such that

$$\sum m_i \ddot{x}_i = 0 \text{ (here } d\lambda = ds)$$

In these special frames, which are distinguished by the uniquely determined relative motion, the equations of motion simplify to

$$M \frac{d}{ds} (\Psi m_i \dot{x}_i) = \frac{\partial \Psi}{\partial x_i} \quad (3)$$

In the last line, for ψ read Ψ

Equation (4) and the next line should read:

$$m_i d\dot{x}_i/dt = (1/M\Psi) \partial \Psi / \partial x_i \quad (4)$$

where $\gamma = 1/M\Psi$ is a gravitational constant that is determined.

Page 329, paragraph 5, line 2 should read:

linear in the \dot{r}_{ij} s to L (gyroscopic-type forces) or multiplying L

Equation (5) should read

$$m_i d\dot{x}_i/dt = (1/M\Psi) \partial \Psi / \partial x_i + (1/M\Phi) \partial \Phi / \partial x_i \quad (5)$$

Biological differentiation -a new journal.

Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon - differentiation.

The first five issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.

Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.

Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Bieseke, J. S. Morgante and M. C. Garrido.

The principle of sequential dependence in cellular differentiation. P. A. Riley.

Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.

Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.

Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.

The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.

DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.

Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.

The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

Essays on the Nervous System

A Festschrift for Professor J. Z. Young

Edited by R. Bellairs and E. G. Gray

The range and depth of the topics in this book bear testimony to the influence of the man to whom it is dedicated. The essays are by leading scientists who have at some time in their lives been guided by, or collaborated with, J. Z. Young. Topics covered range from problems of development, pathology, and sensory and motor systems in peripheral nerves, to neuroendocrinology, peripheral and central pathways of the visual system, synaptology, and higher mechanisms of the central nervous system. Illustrated £11.50

Optical Methods in Ultracentrifugation, Electrophoresis, and Diffusion

with a Guide to the Interpretation of Methods

P. H. Lloyd

This book is concerned with the optical systems which are used in the ultracentrifuge and similar equipment in order to determine the distributions of solutes within transparent solutions. It includes detailed descriptions of the systems, and advice on alignment and how to extract the required information from the optical patterns. £3.95 *Monographs in Physical Biochemistry*

Theory of Elementary Atomic and Molecular Processes in Gases

E. E. Nikitin

Translated by K. J. Kearsley

The experimental investigation of non-equilibrium processes has shown that the calculation of the rate constants of chemical reactions, and their interpretation in terms of molecular parameters, demands a knowledge of the elementary stages of energy transfer in collisions. This book gives an account of the theory of molecular reactions on the basis of the relevant inelastic collision theory and the transition-state method. £14.75

Guthrie and Honeyman's Introduction to Carbohydrate Chemistry

Revised by R. D. Guthrie

For this new edition the text has been completely restructured, rewritten, and up-dated. Some classical carbohydrate chemistry has been omitted and this has enabled the section on glycosides to be expanded, carbohydrate antibiotics to be introduced, and a new chapter on structural studies and systems to be added. Fourth edition. £4 paper covers £1.50

Oxford

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me:

1 NATURE BINDER (I enclose £1.85)

3 NATURE BINDERS (I enclose £5.00)

(Payment may be made in any currency at the current rate of exchange)

Prices applicable only to orders received before the 30th June 1975.

Orders can only be serviced if accompanied by remittance, cheques should be made payable to Macmillan Journals Limited.

reviews

Since India met Eurasia

Ecology and Biogeography in India
Edited by M. S. Mani. (Monographiae
Biologicae, Vol. 23.) Pp. xix+773.
(Junk; The Hague, 1974.) 190 guilders.

INDIA (including Pakistan, Ceylon (now Sri Lanka), Nepal, Sikkim, Bhutan and Burma) provides a particular fascination to biogeographers, for it is the arena where a southern continent, detached from the disintegrating Gondwana continental block in the vicinity of south-east Africa and Madagascar apparently before the Maestrichtian towards the end of the Cretaceous period, finally traversed the Tethys Sea and collided with the southern shores of Eurasia perhaps in the Oligocene. The Indian Peninsula and Ceylon is the surviving fragment, but the Laccadive, Maldive, Chagos and Mascarene archipelagos represent submerged mountain summits of a larger part that collapsed as the great scarp of the western Ghats rose, consequent on the underthrusting of the northern margin of this continental plate beneath the southern margin of Eurasia; the other consequences of this underthrust have been the creation of Ganges-Indus plains and the massive Tertiary orogene that lifted the Himalayas.

It may be supposed that two tropical Cretaceous faunas and floras, having evolved in isolation, met then for the first time: an essentially insular and probably largely oceanic rain forest biome from the south, and a much more diversified continental array in the north among which were nevertheless the once vast but already retreating rain forests which stretched as far as western Europe in the Eocene, whose heirs now clothe the hills of western Malesia and south-east Asia. Subsequently the uplift of the Himalayas has created whole new environments for colonisation and, with the Pleistocene glaciations, has radically altered regional climate, while man has for long and increasingly destroyed or impoverished the Indian environment.

It is the biogeographers' task to explain the distribution of modern biomes in terms of past events, and to trace the origin, migration and diversification of their component taxa. His only direct evidence is palaeontological, which in India is almost completely lacking between the lower Cretaceous and Miocene, and in the Peninsula

decidedly scant thereafter. He must therefore fall back on an unavoidably speculative approach; but, by careful analysis of the phylogeny and ecology of selected groups, whose ecology, behaviour and structure prevent rapid and distant dispersal in relation to their distribution, deductions from repeating patterns can be made. Here he is aided by the rich and distinctive biomes of the Mascarenes, including Madagascar, which contain representatives of many groups that are unable to traverse any but the shortest breaks in their chosen habitat, and which provide valuable comparison with those of the Andaman and Nicobars to the north-east and of northern continental origin.

Professor Mani's massive compendium largely fails to do this: it suffers from inadequate integration of the contributions from different authors, and overreliance on evidence from coincidence of modern distribution patterns alone, presented by lists of species whose ecology, and phylogenetic relationships where they exist, are either not discussed or are overgeneralised. The five introductory chapters on physiography, geology, climate and soils present valuable detail, but lack integration; as one example in many, a section on the microclimate within selected Indian crops is in no way integrated with the theme of the book. The editor's own chapters in particular suffer from lack of maps to summarise the mass of geographical detail and place names quoted. The five chapters on vegetation are particularly thin on ecology and contain many errors of detail. Ceylon is said to contain few endemic genera and species, yet in fact almost one third of the angiosperm species are endemic; *Impatiens* and *Apostasiaceae* are wrongly stated not to occur in Malesia; *Shorea* is described as a characteristic genus of the western Ghats forests, yet the only species in fact occurring, *S. roxburghii*, is extremely local and at the edge of its range there. The absence of tropical Amentiferae—Fagaceae, Juglandaceae, Myricaceae and Hamamelidaceae—and the extreme poverty of Ericaceae and Coniferae is a salient feature of the peninsula and Ceylon demanding phytogeographic discussion, but there is none; the single native peninsular conifer is merely cursorily mentioned as *Podocarpus latifolius* in one

chapter, *Decussocarpus latifolius* in another. Nowhere does the contrasting biogeography and ecology of forest and grassland in the peninsular mountains receive the interpretation it deserves, and indeed these mountains are stated to lack altitudinal zonation which is quite incorrect.

The editor is a zoologist, and the main emphasis is zoological, the five chapters on regional biogeography being in fact entirely zoogeographical. This is reasonable and must depend on availability of authors (though their titles are misleading), but once again the integrated approach is lacking. The book's introduction stimulates the reader with controversial statements dogmatically presented but he is ultimately disappointed to find that, though they are often repeated, their substantiation is never realised: where is the evidence that the original Gondwana flora and fauna were evolutionary "stagnant" or "degenerating" when the Asiatic land connection became established? Indeed, though extensive descriptions of subsequent migrations in and out of the peninsula are included, where in the whole book are the taxa of acclaimed Gondwana origin, upon which this discussion must depend, convincingly identified by reasoned argument? One is led to suspect that, in spite of disclaimers, the evidence lies merely in the evocative but probably irrelevant relict distribution patterns of a wide range of species of clearly different affinities (and origins?) in peninsular biomes that have become fragmented in Pleistocene to recent times.

Yet the evidence is there for the searching. An integrated approach would, for instance, compellingly suggest that the mighty dipterocarp trees, whose present centre of distribution is in the western Malesian rain forests which they so distinctively dominate, are extraordinarily successful immigrants whose origin must be sought in the so-called degenerate and stagnant Gondwana biomes. The distinct distribution of interfamilial links such as the genus *Axinandra*, as well as the isolated and distinctive Nepenthaceae, demand discussion in relation to their ecology. Four chapters are in fact provided on the biogeography of specific animal groups; among them P. K. Sen-Sarma's treatment of the termites, and K. C. Jayaram's of the freshwater fishes, amphibians and reptiles, con-

taining ideal taxa for biogeographical analysis (unlike the butterflies of D. J. Holloway, which are likely to be of too recent origin to have existed in the peninsula before it became disconnected from Africa). Centres of origin should be traceable, but the discussion never reaches a sufficiently detailed level to convincingly do so. Professor Hilary Cruz's work on the ecology of the extraordinary endemic agamid genera in the hill forests of wet zone Ceylon could, for instance, have provided the basis for such a discussion but his work is not mentioned.

The biogeography of the Indian region is not, of course, that of the peninsula alone; separate chapters are devoted to the Indo-Gangetic plain, and the Himalayan region. But though much information is presented as in the rest of the book, these chapters are marred in the same manner. The chapters on the impact of man, and the ecology of 'tribal' man (by P. Lal) are welcome and useful, as are those on recent faunal impoverishment (A. K. Mukherjee), the ecology of vertebrates of the Indian desert (I. Prakash) and the mammals of Assam (G. V. Kurup).

The book is well designed and printed, though spelling errors, particularly in scientific names, are not infrequent.

P. S. ASHTON

Anatomy of experiments

Design of Experiments: A Realistic Approach. By V. L. Anderson and R. A. McLean. Pp. xvii+418. (Statistics: Textbooks and Monographs.) (Dekker: New York, February 1974.) \$19.75.

I HAVE long contemplated the value of a book that would discuss in detail a few experiments in which statistical concepts were vital to the design, the analysis and the interpretation. The declared objective of the book under review is "to express rather complex ideas on how and why scientific investigators should design experiments". Is this the book I want?

Certainly it has many merits. The authors employ a wide range of examples to illustrate the theory and practice of experimental design, choosing these largely (but not entirely) from manufacturing industries of which they obviously have much experience. For the teacher, the examples analysed fully and others outlined as problems for the student will prove useful sources of ideas. Nevertheless, I was disappointed to find attention concentrated on questions that can be answered in terms of currently available theory of linear models for observations. On the structure of analysis of variance and on variance components,

the presentation is good. Little is said about reasons for choosing particular designs. The interpretation of results remains on the statistician's desk, and is not carried to the field of application. Computational methods and problems are not mentioned: even the existence of standard programs and the desirable features of computer input and output are neglected. The anatomy of analysis of variance is thoroughly displayed, but the developmental and operational physiology of experimentation remains unexplained.

The book proceeds through standard designs, from completely randomised to lattices and factorials, in a manner at times refreshingly different from other texts. Without entering deeply into combinatorial problems, clear accounts are given of the partitioning of sums of squares. The dependence of analysis on randomisation and of significance tests on variance components is well emphasised, and the emphasis on the inference space is often illuminating. The text is enlivened by many comments that reflect the authors' familiarity with the particular examples, increasing my regret that they did not choose to make that familiarity a distinctive feature at the expense of some of the more conventional algebra. Had they done so, they might have let the reader see the severe limitations of the Newman-Keuls and other multiple comparison tests which so seldom represent any realistic model of data: they might also have illustrated the full interpretation of analyses of transformed data. The final chapter on response surfaces is an interesting brief survey, tantalising because too short to allow critical comparison of methods and objectives.

D. J. FINNEY

Plant becomes soil

Biology of Plant Litter Decomposition. Edited by C. H. Dickinson and G. J. F. Pugh. Vol. 1: Pp. xiv+1-244+46. Vol. 2: Pp. x+245-775+75. (Academic: London and New York, March 1974.) Vol. 1: £7; Vol. 2: £10.50.

RECYCLING of elements bound in living matter is essential to the continuation of life in our, at present, virtually closed global ecosystem. Since plants form the bulk of the world's biomass and, at least on land, the bulk of this biomass is recycled by the decomposition of plant litter rather than by consumption by herbivores, there can be no doubt as to the importance of the subject matter of these volumes. The excellent introductory chapter on 'Litter—Interface of Animate/Inanimate Matter' gives a broad and stimulating view of the whole field of decomposition studies. Some later chapters, by the nature of their narrower

topics, seem by comparison more mundane in their approach to the ecological issues. Following the introduction, the work is in three parts.

In the first part, plant litter decomposition is treated on the basis of different types of plant litter. Thus there is a chapter on lower plant litter, so important in the transition from rock to soil, followed by chapters on decomposition of herbaceous litter, angiosperm tree leaf litter, coniferous leaf litter, wood and roots. Finally, in part I is a chapter on the nature and decomposition of digested plant litter in the form of animal dung and in the faecal pellets from certain soil fauna. It seems artificial to exclude from consideration in the work the decomposition of plant material which has actively been detached from plants by herbivores or by man for feeding to his herbivorous livestock. Such lines of thought, however, lead to the large, but dubiously separable areas of biodeterioration and ruminant nutrition.

In part 2, the chapters survey different groups of organisms involved in plant litter decomposition ranging from bacteria, actinomycetes, terrestrial fungi, aquatic fungi, protozoa, nematodes, oligochaetes, microarthropods, macroarthropods and molluscs, to aquatic crustaceans. The emphasis in these chapters varies: some provide a brief introduction to the classification of the group whereas others assume the reader's familiarity with the group and devote attention directly to the ecological significance of the organisms in litter decomposition.

This approach to ecological problems of plant litter decomposition seems less thought provoking for the general reader than is the approach through litter types or the chapters in part 3 where decomposition of plant litter is discussed in relation to the environment in which decomposition takes place. These last chapters cover decomposition both on the surface of soil and in the depth of soil, in fresh water and in marine environments. The two final chapters discuss special environmental problems of the breakdown of agricultural crop debris and urban waste. Peat and coal are economically important deposits of partly decomposed plant debris. Surprisingly, these are largely ignored in the environmental chapters, though a forthcoming review on peat, by one of the contributors, may account for part of this omission.

The editors have performed a considerable service in bringing together and indicating the relevance of some 2,000 references. I suspect that the work will be appreciated as a source book mainly by students, though researchers in this field will glean grains of information.

R. C. CODNER

Amoral concepts of biology

Philosophy of Biological Science. By David L. Hull. Pp. xi+148. (Prentice-Hall: Englewood Cliffs, N. J. March 1974.) \$6.95.

In this book, Professor Hull sets out at once to explain to students of philosophy what he regards as the most important laws and concepts of modern biology, and to initiate biologists into a philosophical approach to their problems, therefore assuming in his readers little prior knowledge of either discipline. Hull freely acknowledges the difficulties he has experienced in attempting this in lecture courses addressed to mixed classes of biology and philosophy students, and admits that the aim is a large one for so small a book. It can at least be said that he has achieved his initial aim of making the exposition intelligible to relatively unprepared readers. Students taking courses of the type that Professor Hull delivers will doubtless find this book useful, even though his bibliography is short, highly selective and almost exclusively American.

The extent to which modern professional biologists look to philosophy for guidance in their scientific thought and activity, or to which modern philosophers look to biology as a testing ground for their views on the methods and logic of science, are probably both rather small. One has the impression that biologists tend to develop an interest in philosophy after their main scientific work has finished, generally looking for systems of thought which would justify *post facto* the ways in which they have been thinking. Most philosophers of science, at least within the dominant positivist schools, take the Comtean view, of physics as the paradigmatic science and of biology as a relatively immature and secondary study. It is doubtful whether Professor Hull's book will have any significant influence in changing this situation; neither philosophers nor biologists will find in it any very compelling new insights. Like another recent author in this field, Michael Ruse, Hull seems concerned mainly to provide a respectable articulation of the current American 'conventional wisdom' on the subject. His method of exposition consists in posing a series of philosophical questions about biology, which he proceeds to discuss serially, usually without reaching any very conclusive answers.

Hull's exposition has some very notable omissions—for example, though he is a member of the editorial board of the journal *Systematic Zoology*, and has contributed to it and other journals a series of articles on the theory of biological classification, this topic receives no specific attention in

the book—although most experienced botanists, zoologists and bacteriologists would admit the centrally important role of classification in their sciences (a role with no real parallel in physics), and Michael Ruse devoted two whole chapters to it. Admittedly, one important question posed—but not finally answered—by Hull, does involve the theory of systematics; this question is, to what extent are taxa individuals, with names analogous to proper names, and therefore not permissible in what Hull would recognise as 'laws'? Furthermore, though evolutionary theory is considered at some length, Hull makes no reference to the scientific nature and status of geology—of which it would be quite possible to consider the biological sciences as subordinate parts—nor does he consider the epistemological problems posed by the palaeontologists' claim to knowledge of the organisms of the remote past.

Pride of place in Hull's exposition of biology is accorded to classical and molecular genetics, as domains of what he would accept as scientific 'law'. Yet no reference is made to the profound critique of this conception of genetics by a very eminent geneticist, as expressed in the article "Axiom and Process in Genetics" by C. D. Darlington (*Nature*, 234, 521–5; 1971). Darlington drew attention, among other things, to the nature of the genotype as the embodiment of race history, and to the dual nature of time, as cyclic and as unidirectionally progressive. Almost the only reference to the nature of time in Hull's book is the offhand remark "Both space and time are now viewed as organisational properties of material bodies"—one of the few ontological assertions he makes. Even the second law of thermodynamics, which might call into question this assertion as far as time is concerned, is mentioned only in dismissing the claim by some authors that organisms can violate it.

Professor Hull's omissions have I think a definite tendency—that of excluding from consideration anything which might raise ontological or moral problems. Recent Anglo-Saxon schools have generally equated philosophy with epistemology, dismissing ontology as "metaphysics" and treating ethics as not properly part of academic philosophy. Hull's failure to consider the moral problems posed by modern biology, and especially by modern medical research, is perhaps a little old-fashioned; there is a rapidly growing general consciousness of these moral issues, not least among students. The issues concern, not merely the ethics of experimentation on human beings, but also the proper relations of man to non-human organisms.

The shortcomings of this book are

shared, to a greater or less extent, by most recent treatments of the subject, and should be attributed less to the author than to the general intellectual climate in which he writes. The essential virtue which Professor Hull can claim is that he at least poses a number of profoundly important questions, the serious pursuit of which by students might lead them far beyond his own exposition—which, after all, is an end that any teacher should be proud to have achieved.

R. A. CROWSON

Spoonful of saccharin

Sensory Processes: The New Psychophysics. By Lawrence E. Marks. Pp. x+334. (Academic: New York and London, February 1974.) \$17.50; £8.25.

PEOPLE who use saccharin to sweeten their tea may have noticed a surprising thing: halving the concentration of sugar in a solution reduces its sweetness far more than halving an equally sweet (although much weaker) concentration of saccharin. This is one of many examples that demonstrate differing relationships between sensory magnitude and physical stimulus. How does one measure sweetness, brightness, pitch, odour? It has been shown, particularly in the pioneering work of the late S. S. Stevens, that asking subjects to assign numbers to sensation strength leads to a power function with an exponent dependent upon the stimulus and sensation considered. Lawrence Marks draws a clear distinction between this, the "new" psychophysics, and sensory physics, the "old" psychophysics, in which the observer is simply a detector of threshold, masked threshold, or null point, with measured quantities all in the physical domain. He describes and attempts to interrelate the various psychophysical procedures such as fractionation, category rating, and magnitude estimation and discusses the influences of extraneous factors. The senses are each considered under the headings of sensitivity, temporal and spatial factors, and qualitative aspects. Although one detects a certain antipathy towards the "old" psychophysics it is a carefully reasoned and comprehensive account and shows great concern for validation of the approach. Unfortunately his rather detached attitude coupled with the large number of references makes difficult reading in parts and a certain amount of repetition is inherent in the organisation he has adopted.

Although the new psychophysics gives insights into sensory processes not obtainable in any other way the field has a certain contrived air to it. We do not generally use our senses, or num-

failed, is not that it uses abstract models and traces interdependence between variables, but that it has sometimes been pseudo-planning, confined to a ceremonial superstructure, without being geared to where the action is.

The authors argue for the central importance of the annual budget. Though it is obviously true that no plan can be implemented unless it is integrated into the annual budget, there is a danger of mistaking a necessary, though minor, condition for the strategic one. Budgets are, at best, annual public expenditure plans. A focus on fiscal magnitudes, though essential for proper public accounting, obscures and evades the real activities. Links between fiscal (or even financial) expenditures and results are tenuous, especially in underdeveloped countries. There are no fixed coefficients between money expenditure and land reform, population policy, incomes policy, education, public health, nutrition. Foreign exchange budgeting, manpower budgeting, raw material budgeting are just as important as fiscal budgeting and even they do not exhaust the range of necessary policies. Proper public accounting is necessary to ensure, negatively, that public money is not spent extravagantly or corruptly, but it cannot ensure, positively, that it is spent according to social priorities and that the necessary complementary actions are taken. Budgeting is to planning what bookkeeping is to business management: without it, management is impossible; but with the best book-keeper in the world, a firm can go bankrupt. These points are not enough stressed by the authors, who see the plan essentially as a many-year public capital budget.

Much is made of the need for redundancy. In a piece of exquisite jargon, the authors write: "Broadly speaking, we can regard social poverty as a lack of functional redundancy" (Page 49). But there is a vast difference between reserves (which serve a purpose) and redundancies. A more analytical and quantitative approach would have made the distinction clear. It is now well known that in poor societies, not only unskilled labour, but also capital and technically trained professional manpower are redundant: but, alas, they are not reserves.

The authors make a large number of entirely fair and commonsensical criticisms of planning. "If we were asked to design a mechanism for decisions to maximise every known disability and minimise any possible advantage of poor countries, we could hardly do better than comprehensive, multi-sectoral planning" (Page 293). The need for unavailable information, for political stability, for consistent aims are cited as unattainable condi-

tions. But perhaps the most serious criticism of planning is omitted, viz. that its very success, measured by coherence and consistency, becomes an obstacle to adaptation and innovation. Plans introduce an additional rigidity into societies already inflexible. Plans, for this reason, in spite of their declared intentions, are elements strengthening conservatism.

The conclusion is not, however, reliance on *laissez-faire* and the free play of market forces. The authors rightly point to the need for a combination of contingency planning, continuous budgeting and rolling planning, so that there can be adequate and speedy responses and adaptations to unforeseen events, both favourable and unfavourable.

The authors treat planners and planning as part of the social and political environment which they are supposed to plan. Planning the planners is not an invitation to an infinite regress but a reminder that there must be continuous mutual adaptation between plan objectives and social constraints.

PAUL STREETEN

Details of sense organs

The Ultrastructure of Sensory Organs. Edited by I. Friedmann. (North-Holland: Amsterdam and London; American Elsevier: New York, 1974.) Dfl.90; \$32.70.

THIS collection of four essays is less general than the title implies; only vertebrates are described. Of their sense organs only taste buds (R. G. Murray), the organ of Corti (H. Engström and H. W. Ades), the vertebrate retina (R. F. Dunn) and the olfactory mucosa (P. P. C. Graziadei) are included. The preface indicates the intention of the articles to summarise "the immense and rapid progress that has been made in electron microscopy" for "anatomists, physiologists, pathologists and clinicians". Only Engström and Ades make some attempt to meet the latter two classes of busy people part way. Anatomists are best treated in that all the articles provide descriptive anatomical accounts while remaining substantially innocent of physiological commentary or synthesis of the two approaches.

Thus the essays have to be judged not as summaries of the contributions ultrastructural studies are making to understanding of the mechanisms of action of the organs treated, but as summaries of anatomical information available up until about 1970-71. Most of the summaries are competent but, perhaps because of editorial direction, they all seem of rather even emphasis; so that exciting new developments and the relative importance, or accuracy, of different and differing observations are

hard to discern. Perhaps the main point of the articles was to provide a review of the literature together with an atlas of ultrastructure. There are numerous electron micrographs including a fair number, especially of the retina, that have not previously been published. For the non-specialist in a particular sense organ the essays provide a reasonably readable guide to the literature of the past twenty years. There are useful summary tables of data, for example in the article on the retina. But for the readership suggested, and given that the articles are purely anatomical, a greater use of summary diagrams, perhaps at the expense of some of the electron micrographs, would have been more helpful to ready comprehension. The essays are probably most useful for someone beginning an interest in the structure of a particular sense organ. Most people are likely quickly to prefer the more detailed and often more synthetic articles of the currently appearing *Handbook of Sensory Physiology*.

B. B. BOYCOTT

Computers in mathematics

Computer Approaches to Mathematical Problems. By Jurg Nievergelt, J. Craig Farrar and Edward M. Reingold. Pp. xii + 267. (Prentice-Hall, Englewood Cliffs, 1973.) \$8.95.

AFTER an introductory chapter on languages, including some remarks on the parenthesis notation and the polish notation, there is a chapter on combinatorial computing. This includes a discussion of block designs, latin squares, scheduling and tiled rectangles; and also an account of various graph algorithms, for shortest paths, spanning trees and sorting. There follows a chapter on the use of computers in game playing and decision making and another chapter on random numbers and their use in Monte Carlo methods and in simulation. Computing in number theory is next considered and there is a review of the position in the computing of $\sqrt{2}$, e and π . For example, in 1967 the value of π was computed to 500,000 decimal places. Finally there is a section on the use of computers in calculating large prime numbers. The largest known Mersenne prime, by 1971, is $2^p - 1$ where $p = 19937$. The book closes with a chapter on logic and computers.

This book will be of particular interest to the mathematician interested in the use of computers in pure mathematics. But in this connection, it is a little surprising to find no reference to the use of computers in the theory of finite groups. It will also be relevant for students of operational research mathematics.

L. S. GODDARD

Comprehensive mineralogy

Modern Mineralogy. By Keith Frye. Pp. ix+325. (Prentice-Hall: Englewood Cliffs, NJ, 1974.) £6.50.

MANY new mineralogy textbooks have appeared during the past decade; most have been devoted to specialised subjects and these have tended to replace the earlier type, which aimed at providing for the whole of a student's requirements up to the level of the first degree. With advance of knowledge and the need to explain quite sophisticated techniques even in an elementary book, it is no longer possible to provide a comprehensive text at an adequate level without making the volume unduly expensive, cumbersome and forbidding. Specialised books necessarily contain a much fuller treatment than the average student requires at an early stage but the rapid escalation in book prices has now reduced their attraction for purchase by students. To some extent this has restored the need for a new type of comprehensive text and this book is a valiant attempt to meet just this need. It is selective, it omits much of the conventional crystallographic introduction, and its stated purpose is to provide a sound physically-based approach through familiar atomic theory and crystal structures in a logical sequence, and to introduce the student to present-day concepts of mineral formation and equilibrium. How well does it measure up to these rigorous requirements?

There are seven chapters and a 25-page tabular appendix of data on 150 common minerals. Chapter one is a fairly conventional crystal-chemical introduction that considers the nature of chemical bonds, close packing, ionic radii, simple model structures, defects and solid solution. It is pleasant to note the attention paid here to chemical and structural defects, to dislocations and to the evolution of grain boundaries. Chapter 2 provides a systematic account of the crystal structures found in minerals; again it follows a conventional treatment except where the model-structures theme is developed attractively by way of stuffed derivatives to explain many common rock-forming silicates. There follows in chapter 3 an all-embracing exposition of crystal symmetry, including lattices, point groups, the stereographic projection, crystal morphology, twinning and mineral habits, in 60 glorious pages. Logic seems to have quite deserted the author at this stage, for crystal structures have already been explained and many of the topics introduced (such as space groups) are certainly not needed for what follows. Chapters 4 and 5 are shorter; they are concerned with physical properties and the interaction of radiant energy

with crystalline material. Topics dealt with here include mechanical behaviour, radioactivity, surface properties (but not pyro- and piezo-electricity) colour and lustre, atomic absorption, justification of the optical indicatrix, and the principles of X-ray diffraction. Although this is attractively presented, as in chapter 3 it is difficult to understand why so many principles are explained, albeit briefly, when no attempt is made to show how to use them. This middle part of the book is rather like Hamlet without the Prince of Denmark!

Chapter 6 is probably the best part of the entire book; it is excellent. Beginning with a concise and lucid explanation of the phase rule, it passes on to consider phase diagrams. It deals mostly with crystallisation and melting relations in binaries and ternaries, but regrettably does little on 3-phase triangles or on working out detailed courses of crystallisation. It then introduces isothermal and isobaric sections (used in the final chapter) and then passes on to a brief consideration of a quaternary system with a vapour phase. The final chapter spans an even vaster canvas—the whole of petrology! It begins with an enunciation of the principles of geochemistry and mineral formation and then proceeds to consider the classification and petrogenesis of igneous, sedimentary, and metamorphic rocks as well as some aspects of ore deposits. Although much of the treatment here is skilfully conceived as a consummation of all that has gone before, the familiar symptoms of extreme compression and a plethora of quite difficult new concepts, criticised earlier, here becomes a veritable disease. This must render the chapter virtually useless to an elementary student as a first reading. The repeated misuse of 'lattice' for 'structure' here is deprecated. I cannot see any value in the appendix, which is not sufficiently comprehensive to be of much use for identification yet takes up valuable space.

The diagrams are clear and well drawn but a few minor errors were noted (Fig. 6.13a). Separate author, mineral name and subject indexes are provided.

The author deserves full credit for producing an original, thoughtful and always interesting book which omits much of the irrelevant and otiose morphology still on offer in many. I do not wish to be pejorative but far too much has been attempted, the result being a book that is not really adequate as a crystallography, mineralogy or petrology text. It does not explain how to determine a point group, analyse a stereogram, use a polarising microscope or obtain information from an X-ray photograph. It does not explain the detailed reading of phase diagrams or

how to describe a rock. Nevertheless it contains much information of value not easily found elsewhere and sections can be strongly recommended as further reading by more mature students and as a source of good ideas for elementary teaching. The author has demonstrated his ability to explain difficult ideas clearly, but the book would have fulfilled its rôle as a mineralogy text better if the final chapter and appendix had been omitted, the space saved being used to explain practical aspects of optics including some mention of reflected light, to expand the X-ray section, and to say more on solid solution in rock-forming minerals.

I. D. MUIR

Microscopy for all

The Encyclopedia of Microscopy and Microtechnique. Edited by Peter Gray. Pp. xi+638. (Van Nostrand Reinhold: New York and London, January 1974.) £16.25.

IN recent years methods of microscopy and microtechnique have expanded at such a rapid rate that it is almost impossible to remain abreast of current developments in all but a small area of specialisation. This not only makes the provision of extensive reference books essential, it renders the task of their compilers almost impossible. The present book is, as the editor states in the preface, an attempt to cater for the needs of all who use the microscope, not only in the medical and biological sciences, but also among the "atmospherologists, bakers, chemists, metallurgists, textile workers, the manufacturers of paints and those who examine paintings". With such an implied wide-ranging coverage in mind, the need for interdisciplinary communication (especially with regard to such a basic tool as microscopy) is clearly apparent and the attempt is praiseworthy. In practical terms, however, it seems that it is not entirely successful. One wonders what the textile worker or paint manufacturer who uses the microscope will gain from the inclusion of a long description of the morphology and systematics of the annelids.

An attempt to cover the whole spectrum of possible microscope usage must fall far short in some fields and it seems that the basic fault of this book lies here. Had the coverage been limited to the instrument and to basic preparative techniques, the value of the book to all users of the microscope would have been increased and the topics could have been covered in more detail.

Most of the articles in this book (provided by about 180 specialists) are short, only one or two pages in length,

and so cannot provide more than a very superficial coverage of the subject. There is, however, a list of references after most articles which serves as an introduction to sources which provide more detailed information. As might be expected, there is a considerable variation in the standard of the individual articles. Some provide an excellent thumb-nail sketch of the subject whereas others contrive to say very little indeed. The production quality is good and there are surprisingly few misprints for such a large book (although some inconsistencies have crept in, Abbe's name being rendered variously as Abbé or Abbee for example). The index is an essential feature of any reference book and in this case it is perfectly adequate.

S. BRADBURY

Raman analysis

Applications of Laser Raman Spectroscopy. By Stanley K. Freeman. Pp. xi+336. (Wiley: New York and London, January 1974.) £9.75.

THIS new book on the applications of Raman spectroscopy is the most significant modern volume to survey the analytical value of laser Raman spectroscopy. It includes a compendium chapter on the principles behind the Raman and related effects and others on experimental technique, a long section on qualitative analytical applications and concludes with chapters on synthetic and biopolymers and the value of Raman methods in pollution studies.

Molecular vibrations are normally studied by infrared absorption and Raman scattering. Since the vibrations characteristic of a complex molecule are themselves complex, these two techniques can, in principle, provide excellent fingerprints of analytical value. Infrared spectroscopy has been used routinely in this way for more than thirty years but Raman spectroscopy has not. Forty years ago Raman spectroscopy was thought to have immense analytical potential but it became clear in the later 1930s that experimental limitations severely restricted the versatility of the method. The relatively recent advent of the laser and sophisticated commercial spectrometers have improved the situation dramatically with the result that Raman spectroscopy is now playing an invaluable part both as an analytical tool (in the broadest possible sense), in structural chemistry, solid state physics and many other diverse areas.

In his book, Freeman selects some of the analytical applications of Raman spectroscopy and discusses these in considerable detail. Since other books exist covering infrared and Raman

spectra of crystals, and reviews abound in other detailed areas, he quite rightly spends most of his time on the area in which he is best known and which is worst surveyed elsewhere: the use of Raman spectroscopy for functional group identification in organic analysis. In this area, the book is unique and contains a wealth of otherwise unpublished data and the significant results of years of experience. In fact, it can be truthfully said to be the logical successor to the classic books in this field by Hibben and Kohlrausch, both published before 1940!

In the chapters on polymeric and biological compounds the coverage is again chemical and analytical rather than structural and little space is spent in considering the niceties of vibrational theory and structural consequences thereon. But in the context of the book as a whole, this is entirely relevant. The section on pollution monitoring and Remote Raman techniques is also valuable in that it surveys a field which is very diversely covered in the literature.

My initial reaction to Freeman's book was most unfavourable since the title is misleading. Nowhere convenient does the author point out that to him "applications" mean analytical ones, thus many will be disappointed by the narrow coverage and extravagant claims on the dust cover. Further, the production quality is reminiscent of a cheap paperback. But once the first chapter is digested and the general tenor of the coverage grasped, the book endears itself to the practicing chemical vibrational spectroscopist.

P. J. HENDRA

Aluminium analysed

Analytical Chemistry of Aluminum. By V. N. Tikhonov. Translated by J. Schmorak. Pp. x+303. (Analytical Chemistry of the Elements.) (Halsted, Wiley: New York, Toronto and Chichester; Israel Program for Scientific Translations: Jerusalem, January 1974.) £9.55.

THIS latest volume in the series of monographs dealing with the analytical chemistry of the elements, and sponsored by the USSR Academy of Sciences through the Vernadskii Institute of Geochemistry and Analytical Chemistry, is concerned with aluminium (*sic*).

The contents follow the general pattern established in previous volumes. A short preliminary chapter details relevant information about the occurrence, the physical and chemical properties of aluminium and its compounds, particularly the properties of complexes of the element with organic compounds which have found use as

analytical reagents. Chapter 2 contains an extensive account of chemical and physicochemical methods for the determination of aluminium, in which gravimetric, titrimetric, photometric and fluorimetric methods are given comprehensive coverage, rather less space being devoted to polarography, radioactivation and spectroscopic methods. Chapter 3 deals with the separation of aluminium from accompanying elements by precipitation with inorganic and organic reagents, by extraction, by a variety of chromatographic methods and by mercury cathode electrolysis. Chapter 4 treats the determination of aluminium in natural and industrial materials such as minerals, ores and industrial concentrates, soil, water and organic substances, metals and alloys. Chapter 5 brings the text to a conclusion with a description of methods for the determination of impurities in high-purity aluminium. The bibliography of work cited in the text contains over 1,300 entries. As with the earlier volumes in this series, the translation has been expertly done.

As the third most abundant element in the Earth's crust, aluminium is present in most natural and fabricated materials. Although its chemistry and hence its analytical chemistry is not particularly complicated, a vast literature on methods for its determination, particularly in the presence of interfering elements, now exists. Surprisingly, no attempt has been made to review this information since 1942, when Fischer contributed a monograph on the subject in the *Handbook of Analytical Chemistry* by Fresenius and Jander. The present text deals mainly with the literature up to 1968 with occasional later references, none, of course, beyond 1971, the year of publication of the original Russian version, and covers all known methods for the determination of aluminium.

There can be no doubt about the value of this type of monograph to the practising analyst. Many of the problems associated with the analysis of aluminium—the ignition temperature of aluminium oxide, the pH for precipitation of aluminium 8-hydroxyuolate, the difficulties of the complexometric titration, the volatilisation of aluminium for AAS, the best photometric reagent for a particular purpose—all are given thorough and realistic treatment. Although this book is essentially a review of existing literature, perhaps a major benefit is its presentation of Russian work not readily accessible to analytical chemists in the Western World. As a comprehensive and authoritative source of information on the analytical chemistry of aluminium, it must assume the premier role.

W. I. STEPHEN

Science in the media

Two contrasting looks at the place of science reporting in the media—one from each side of the Atlantic—have recently combined to provide an insight into the delights and pitfalls of science journalism, while showing how different these are in different countries. In Britain, the BBC Radio 3 programme "The Communicators" looked at science reporting in its issue of July 27. Here, the emphasis was squarely on the difficulties involved in getting a science story into the British national press at all.

The situation in this respect has deteriorated over the years, as the long serving science correspondent of the Daily Express recalled. With shortage of newsprint and a feeling that the public is to some extent disenchanted with hard science, it is all too easy for science journalists to fall into the trap of overdramatisation, at least in the eyes of the scientists. Several scientists interviewed in the programme expressed their concern about sensational reporting—one was distressed by a comment from one of the people making a documentary about typhoid that "we are in this game to entertain the public, not to educate them".

Such concern about sensational and inaccurate reporting is also felt on the other side of the Atlantic, to judge from an 'occasional paper' on *Science in the Newspaper* which has recently been published by the American Association for the Advancement of Science. But in many other respects the situation in the USA seems far different from that in Britain, giving the lie, perhaps, to any suggestion that sensational reporting arises because of the difficulty of getting any science story into print.

Science in the Newspaper itself is an odd mixture; contributions from award winning writers discussing their craft rub cheek by jowl with 'scientific' investigations of science reporting, complete with jargon and footnotes. Whether by accident or design, this neatly emphasises one point: the scientists certainly do need help in communicating their ideas to anyone outside a restricted circle of specialists.

Perhaps the most worrying contribution describes the result of a survey of what scientists think about science in the newspaper. The scientists had been asked to check for errors published in stories about their own work, and in more than 25 per cent of the cases they noted such damaging errors as misquotations, misleading headlines, omission of relevant information and excessive brevity.

But are the criteria scientists apply too strict, bearing in mind the audi-

ence for which the articles were intended? When one respondent objected that in a report of the drop out rate of college students the first sentence said that more than half of the college students 'failed to obtain degrees' when it should have been qualified to add 'within four years', the criticism seems valid; but, we are told, the report in question did actually contain the important qualifications in its next sentence. That was not good enough for the scientist whose work was being described, but I would find it difficult to see his objection as one to worry the reporter who made the 'error'.

The point is, of course, that newspaper readers, by and large simply speak a different language from scientists, and that the journalist is literally in the position of interpreter. So many of the irritations felt by scientists are on the same level as the quibbling among multinational organisations about exactly how a French word in an agreement, say, should be translated into German.

This interpretative role is made abundantly clear in the most heartening article in *Science in the Newspaper*. The *National Enquirer* is an American weekly that was until a few years ago, we are told, a 'scandal sheet'. But now the *Enquirer* has changed its image, become a 'family newspaper' and just about quadrupled its circulation, to 4 million. And in that large circulation paper, science has a vital role.

In one recent 48 page issue mentioned, five per cent of the space was given up to science or medical stories. The treatment of these stories is dramatic, and successful in reaching a wide audience who respond with floods of letters. Not all the scientists whose work makes the pages of the *Enquirer* are pleased—Dr Sol Spiegelman, of Columbia University's Institute of Cancer Research, is quoted in *Science in the Newspaper* as being particularly unhappy about the treatment he received from the *Enquirer's* reporters.

But you can't please all the people all the time, and if a paper like the *Enquirer* can, by and large, encourage its readers to accept science as a valuable part of modern society which deals with problems that are relevant to the man in the street, the science journalists are doing their job. The success of the *Enquirer's* science policy ought to make some British popular newspapers rethink their attitude to science; the scientists might not always approve of the result, but then, non-scientists do not always approve of the activities of scientists.

The message from both of these slightly narcissistic looks in the mirror

emphasises a feeling which already exists in both the USA and the UK. Science today must be relevant to the problems of today, and what is more it must be seen to be relevant.

JOHN GRIBBIN

Easy listening science

Over the past few weeks Saturday morning listeners to BBC Radio 4 have been having a taste of up to the minute reports from the scientific world. "Science Now", as its title suggests, has been keeping its audience abreast of the latest developments in science and techniques involved in anything from building a skyscraper from the top downwards to the possible hazard to the public from the development of new strains of mutant cells.

The BBC's radiophonic workshop provides a snappy piece of introductory music which sets the tone for a tightly packed programme of comment, interview and discussion. The presenter, Brian J. Ford, manages to maintain the tempo throughout, and it is this which seems to make the programme such easy listening.

Each thirty minute programme can cover a range of scientific topics acceptable both to working scientists and to the man in the street with an interest in science. When 'test tube babies' hit the headlines recently, "Science Now" covered the subject and brought out the implications in non-sensational terms. As Brian Ford said, the work represents "an interesting development, but not by any means a terrifying prospect".

In the same programme the question of how massive the Universe is and the eventual slowing down of its expansion, was discussed. But as seems inevitable in any science programme today, medical items receive a good share of attention. Audience response indicates the understandable popularity of medicine, but it does seem a little unfortunate that this sometimes serves to divert a large proportion of the very limited air time available for science (see *Nature*, 250, 362; 1974) away from 'hard science'.

Still, a complete edition of "Science Now" was devoted to applied science and included oceanography, crop irrigation, building methods, cancer research and an exhibition to celebrate the discovery of oxygen 200 years ago.

Where the programme differs from some of its predecessors is in the amount of comment provided by the presenter, either with or without contributions from a second party. This is a significant and worthwhile development, since often the caution of a

scientific paper, which might be the peg for an item, masks an exciting development. Equally, of course, Ford has scope to comment about developments, such as the 'test tube baby' story, where exciting publicity has masked the reality of a small and cautious scientific step, forward.

Given that such a programme must, to a large extent, reflect the personal approach of presenter and producer, "Science Now" is doing a good job. It seems unfortunate, however, that it is broadcast only once a week, at a time when many would be listeners must be involved with the ritual of

weekend shopping and/or sport. Although much of the same ground is covered by *New Scientist* or the national press, it would still be good to have a second opportunity to hear the programme, perhaps on a weekday evening.

SALLY OWEN

obituary

Chu K'o-Chen

CHU K'O-CHEN, one of China's most distinguished scientists, Vice President of Academia Sinica, died last February at the age of 84. When I first met him in 1944 he was President of Chekiang University, then in exile in the little town of Mei-t'an in Kweichow Province. One could soon glimpse the qualities which endeared him to generation after generation of Chinese scientists—a real lover of the things of the intellect and of Nature—small of stature, kindly, judicious and compassionate.

His original training in geography, meteorology and astronomy was gained at the University of Illinois in 1917 and subsequently at Harvard. After he returned to China he became Director of the National Meteorological Institute of Academia Sinica at Nanking. Later on, after the Second World War, he was called from Chekiang University to become one of the Vice Presidents of the newly reconstituted National Academy of Sciences. Apart from his early publications in geography and the

techniques of meteorology, he acquired a life-long interest in phenology (historical meteorology). Thus it came about that Chu K'o-Chen led a whole group of scientists in the study and analysis of China's climatic changes over more than 5,000 years.

Another great interest of Chu K'o-Chen was the history of astronomy in Chinese culture. He published a number of papers on such subjects as the origin of the twenty-eight lunar mansions (*hsiu*) and the development of calendrical science. It was natural, therefore, that he should exercise a beneficial influence on such studies in China, and he was one of the founders of the Institute of the History of Science some years ago in Peking, where it occupies the lovely old buildings of a former Manchu prince's palace.

Many Western scientists who have worked in China have been greatly indebted to Chu K'o-Chen for his kindly understanding and never failing help. Two pictorial reminiscences of him come especially to my mind. First at Ts'un-yi, giving a warm welcome to

some wandering European scientists in 1944 with the aid of the delicious *pao-tzu* (stuffed dumplings) made in that place and cooked traditionally on beds of pine needles. Secondly, at the International Congress of the History of Science at Florence in 1956, Chu K'o-Chen led a distinguished Chinese delegation. When we all went out to Vinci to pay our respects at the farm where Leonardo was born, and to visit the castle of the little town with its museum of Leonardo's inventions, we, as an international convention, received an unexpectedly enthusiastic welcome from the *podestà* and the people of Vinci. They regaled us with a splendid lunch and with an al fresco supper where they pressed upon us flasks of the excellent local wine. The Chinese and Japanese delegates, having come from so far away to pay homage to Leonardo, were particularly appreciated by the *cittadini*, and the sight of Chu K'o-Chen and his colleagues leaving for the bus with as many flasks as they could possibly carry remains one of my happiest recollections in the world of international science and its history.

Announcements

Awards

Alasdair Muir Breckenridge has been awarded the **Paul Martini Award 1974** by the Medizinisch Pharmazeutische Studiengesellschaft eV, Frankfurt.

Chaim Leib Pekeris has been awarded the **1974 Vetlesen Prize in Earth Sciences** by the University of Columbia.

Appointments

Bernard Salvage has been appointed to a personal chair of high voltage engineering at **Heriot-Watt University**.

W. A. Cramond has been appointed Principal and Vice-Chancellor of the **University of Stirling**.

Errata

In the article "Elongation factors for chloroplast and mitochondrial protein synthesis in *Chlorella vulgaris*" by O. Ciferri and O. Tiboni (*Nature new Biol.*, **245**, 209; 1973) some of the references in the text were wrongly numbered. The following corrections should be made: in Table 1 and Fig. 1, 3 should be 6; 4, 7; 5, 8; 6, 9; 7, 10; in Fig. 2, 9 should be 12; in the text on pages 210 and 211, 10 should be 13; 11, 14; 12, 15; 13, 16; 14, 17; 15, 18; 16, 19; 17, 20; 18, 21; and 19, 22.

In the article "Dietary preference and diseases of age" by M. H. Ross and G. Bras (*Nature*, **250**, 263; 1974) an error appeared in Table 1. The third number down in the penultimate column should read 77" not 7".

Corrigenda

In the article "Early visual adaptation in goldfish retinal ganglion cells" by A. J. Afanador and A. J. Adams (*Nature*, **250**, 346; 1974) the last line of the legend to Fig. 2 should read " 0 corresponds to $7.2 \times 10^{15} \text{ s}^{-1} \text{ cm}^{-2}$ ".

The following corrections should be made to the article "Platelet contractile regulation in an isometric system" by I. Cohen and A. de Vries (*Nature*, **246**, 36; 1973): line 41, $0.2 \text{ g min}^{-1} \text{ cm}^{-2}$; line 43, 1.8 g cm^{-2} ; Fig. 1 "... expressed in g cm^{-2} "; Fig. 2 ordinate Tension (g cm^{-2}) legend, "... expressed in g cm^{-2} "; Fig. 2 ordinate Tension (g cm^{-2}); Fig. 4 legend, Clot contraction model.

Gas Analysis Instrumentation

Anthony Verdin

The detection and analysis of gases and vapours has become essential in many areas of modern life; noticeably industrial safety and control of the environment. As a result a whole class of physio-chemical methods has come into existence. The author draws on his fourteen years of experience in the field to supply the only wide-ranging view of all types of equipment presently available. Both academics and industrialists will find it indispensable.

£9.50

Electrical Breakdown in Gases

Edited by J. A. Rees

The electrical breakdown of gases has been studied in the laboratory since before the start of this century and it is sixty years since Sir J. S. Townsend wrote his monograph *The Theory and Ionisation of Gases by Collision*. In that time the subject has been widely studied and a great deal of progress has been made in understanding many aspects of the problem. J. A. Rees has selected the major papers in this field and has linked them with comments and an introduction. Reprinted from the original sources, the papers together provide a unique introduction to the ionisation of gases.

£7.95

Introduction to Space Charge Electron Optics

G. A. Nagy and M. Szilagyi

This introduction to space charge electron optics is an updated translation of an original Hungarian publication which presents to the West for the first time a comprehensive survey of the vast work carried out in this field in the USSR and Eastern Europe. It is however more than just a summary of literature as it also contains the solution of many problems and so points the way to future developments.

£9.00

Macmillan

THE ALGAE

Second Edition

V. J. Chapman and D. J. Chapman

A completely rewritten and updated second edition of this successful student text. Information included ranges from a taxonomic survey of the principal divisions, classes and orders of the algae to a discussion of such topics as Ecology, Physiology and Bio-geography. Although the overlying approach of the book is general rather than specific few student texts are so comprehensive in their coverage.

£6.95

EVOLUTION AND PLANTS OF THE PAST

Harlan P. Banks

A wide-ranging discussion of a number of important aspects of palaeobotany. The basis of the approach is an examination of the way in which plants have developed from the earliest times, but in contrast with the more traditional approach, in which each group of plants is examined separately, this book looks at each geological period and treats its fossil flora as a whole. 'Dr. Banks' successful blend of scholarship and zest is manifest, and this book can be thoroughly recommended to students of palaeobotany'.

APPOINTMENTS VACANT

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (UNIVERSITY OF READING)

INFORMATION OFFICER

An information scientist, preferably with a degree in microbiology or biochemistry, is required to take part in the new information service of the Institute.

Appointment will be in the Scientific Officer Class, with a starting salary dependent on qualifications and experience. Present scales Scientific Officer £1,592 to £2,675; Higher Scientific Officer £2,461 to £3,371. At least five years' relevant post-qualifying experience is required for appointment in the higher grade. The post is pensionable.

Apply on forms obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT. Quote reference 74/20. (630)

SYDNEY HOSPITAL

New South Wales

Australia

Staff Specialist in Intensive Care

Applications closing September 15, 1974, are invited from suitably qualified medical practitioners for the position of Staff Specialist In Charge of the Intensive Care Unit at Sydney Hospital.

Teaching at both undergraduate and postgraduate levels is an integral part of the position.

Salary and conditions are those set out in the Hospital Specialist (State) Award (range \$A15,203 to \$A21,006). The Award is presently under review. The limited right of private practice is available under the terms laid down by the Health Commission of New South Wales in circular 72/78. The terms allow earnings up to 16 per cent of base rate salary.

Under certain circumstances The Board may give consideration to two part time appointments to this post. Further enquiries may be directed to The Director of Anaesthesia.

Sydney Hospital is a 460 bed teaching hospital of the University of Sydney. It conducts a wide range of medical, surgical and special surgical services and is accredited for post graduate training in general and special medicine and surgery.

The Director of Anaesthesia will be visiting the United Kingdom in August/September. Applications in writing, stating age, training, experience and the names of three referees should be directed as follows:-

1st copy to Dr F. R. Berry, C/- Bank of New South Wales, 9-15 Sackville Street, London.

2nd copy by airmail to The General Medical Superintendent, Sydney Hospital, Box 1614, GPO, Sydney, 2001, New South Wales. (610)

SUBSCRIPTION – REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of a twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

POSTAL CODE

Registered No. 785998 England. Registered Office: 4 Little Essex St. London WC2R 3LF

Pharmacologist/Toxicologist

Servier Laboratories is a subsidiary of a French Pharmaceutical group with an international reputation for research based products and is located in attractive modern offices to the West of London, close to Perivale Central Line underground station.

A vacancy has arisen for a Pharmacologist who has several years post qualification experience in both Pharmacology and Toxicology, and who has acquired knowledge of submissions in this field to registration Authorities.

He or she will be responsible to the Research and Development Manager for the planning and organising of pharmacological and toxicological studies throughout the U.K. This will involve regular contact with outside research specialists. There will also be close liaison with our French parent Company, involving some travel to Paris and a working knowledge of French would therefore be an advantage but is not essential. The provision of a company car will be considered depending on the amount of travelling involved and other benefits include annual bonus, four weeks holiday a year, pension and life assurance scheme, B.U.P.A. and the opportunity to work flexible hours.

Applications to Malcolm Townsend, Personnel Manager, telephone 01-998 2939 or write to him at Servier Laboratories Ltd., Servier House, Horsenden Lane South, Perivale, Greenford, Middx UB6 7PW (715)

LABORATORIES LIMITED

servier

MATERIALS SCIENTIST

Department of Biomedical Engineering,
Institute of Orthopaedics (University of London),
Brockley Hill, Stanmore, Middlesex HA7 4LP.

A vacancy exists for a Materials Scientist to study basic factors concerned with lubrication, wear, fatigue and corrosion of plastics and metals used in the manufacture of orthopaedic implants. Applicants must be graduates in materials science or in an allied discipline and have had reasonable experience in the types of technological problems with which the post is concerned.

The post is grant aided and will be for three years in the first instance. The commencing salary will be £3636 rising to £3990 (plus London Allowance). Further details can be obtained from Professor John T. Scates, to whom application should be made with curriculum vitae and two referees by 14th September 1974. (717)

CHARING CROSS HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON)

The Animal Unit requires a RESEARCH ASSISTANT to collaborate with the Veterinarian in charge in the establishment of a quality control laboratory. The post would be suitable for a graduate or similarly qualified person with a background in microbiology or a relevant biological science. Starting salary not less than £1,350 depending upon experience.

For further information please contact: Head of Animal Unit, 55 Aspenlea Road, London W6 9HH. Telephone 01-385 7709. (628)

"METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS. The work consists of editing, indexing, and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, 1 Carlton House Terrace, London SW1Y 5DB. (633)

UNIVERSITY OF BRITISH COLUMBIA DEPARTMENT OF PHARMACOLOGY

Two assistant or associate professors to be appointed by July 1, 1975;

- (a) one PHARMACOLOGIST, PhD and/or MD;
- (b) one CLINICAL PHARMACOLOGIST, MD and PhD or equivalent plus specialty qualifications.

Salary to be negotiated. Duties include teaching and research. Applications including curriculum vitae and the names of three referees to be sent to Dr. M. C. Sutter, Head, Department of Pharmacology, University of British Columbia, Canada, V6T 1W5, by December 1, 1974.

An Equal Opportunity Employer, M/F. (702)

WEST BERKSHIRE HEALTH DISTRICT MEDICAL PHYSICS TECHNICIAN

for the modern Isotope Laboratory at the Royal Berkshire Hospital, Reading, for interesting work in the chemistry and physics of medical isotope techniques. Post will be on Grade V or Grade IV (£1,308 to £1,677 or £1,530 to £1,953). Day release for further training possible. (Normally O.N.C. or 2 'A' levels required).

Reading is a pleasant University town offering easy access to London, Oxford, Windsor, Henley and attractive surrounding countryside.

Written applications with relevant details and naming 2 referees to the Hospital Secretary, Royal Berkshire Hospital, London Road, Reading, Berkshire. (642)

MEDICAL RESEARCH COUNCIL VIROLOGY UNIT INSTITUTE OF VIROLOGY UNIVERSITY OF GLASGOW

A vacancy exists for an Immunologist on the scientific staff of the M.R.C. Virology Unit. Applicants should be experienced in immunological techniques and able to take responsibility for the immunological side of investigations with herpes virus. A considerable interdisciplinary effort, using a combination of biochemical, genetical and virological techniques is already under way and it will be the candidate's role to add immunological know-how and bring an immunological attitude of mind to the combined approach. The Immunologist would have the full time services of a technician.

The appointment in the first instance, will be for 3 to 5 years on the non-clinical scientific staff with salary starting at an appropriate point on the Grade II scale (expected scale from October 1974, £2,019 to £3,636) F.S.S.U.

Applicants should send a Curriculum Vitae giving full details of qualifications and experience, and the names of three referees to Professor J. H. Subak-Sharpe, Institute of Virology, University of Glasgow, Glasgow G11 5JR by September 20, 1974. (728)

MEDICINAL CHEMISTRY

Career opportunity for experienced HNC/graduate

Our Chemical Research Department is concerned with programmes of synthesis directed towards the discovery of novel therapeutic agents for a range of human and veterinary conditions.

We need an additional experienced H.N.C./graduate to become a key member of one of our research teams.

The person we have in mind will have a wide knowledge of synthetic organic chemistry with an outstanding ability and record of achievement as an experimentalist in this field.

He/she will have had approximately ten years post-

qualification experience in the pharmaceutical industry and be used to supervising and training junior staff.

The ideal applicant will command a starting salary of c. £3,000 p.a. (plus threshold payments). Salaries are reviewed annually and a bonus scheme is in operation.

Other terms and conditions of employment include pension and death benefit scheme, sickness benefit scheme, assistance with removal costs and flexible working hours.

Our modern laboratories are situated in a pleasant rural coastal area at Sandwich, Kent.

Pfizer

Applications, giving age and brief details of experience should be addressed to:—

**G. Marshall, Personnel Officer, Central Research,
Pfizer Limited, Sandwich, Kent CT13, 9NJ (720)**

UNIVERSITY OF GLASGOW POSTDOCTORAL RESEARCH APPOINTMENTS

Applications are invited from Organic Chemists for two Postdoctoral appointments tenable from October 1, 1974.

The first is for one year for research on the Biosynthesis of Fungal Antibiotics at a salary of £2,247 per annum. F.S.S.U.

The second is for two years for research on the Biosynthesis of a Novel Fungal Metabolite at an initial salary of £2,247 rising to £2,412 per annum. F.S.S.U.

Further details may be obtained from Dr. N. J. McCorkindale, Department of Chemistry, The University of Glasgow, Glasgow, G12 8QQ.

In reply please quote Ref. No. 3520 M. (724)

UNIVERSITY OF WARWICK RESEARCH TECHNICIANS

The Department of Biological Sciences has vacancies for a permanent appointment and also one to three year contract posts for technicians in the Microbiology and Virology Research Laboratories. Applicants should have experience in microbiology and/or biochemistry and possess appropriate qualifications. Salary on the Technician Grade 3 scale £1,650 by £54 to £1,920 p.a. plus threshold payments. Applications in writing to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 1/D/74 by August 21, 1974. (725)

DUDLEY AREA HEALTH AUTHORITY

Applications are invited for the post of BASIC GRADE BIOCHEMIST in the Group Biochemistry Laboratory at the Guest Hospital, Dudley. The successful applicant would be expected to contribute significantly to the routine service offered by the department as well as to the expansion of the service. Whitley Council conditions of service apply. Candidates may visit the department by arrangement with Mrs. P. A. Jones, Principal Biochemist, Telephone Dudley 53304 Ext. 7.

Applications, quoting names and addresses of two referees to: Hospital Secretary, The Guest Hospital, Tipton Road, Dudley. (722)

KINGSTON POLYTECHNIC RESEARCH ASSISTANT SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES

to study ultrasonically induced damage in biological material and the mechanisms by which this occurs.

Applicants should be honours graduates in a physical science or biology. You would be encouraged to register for a higher degree. Salary £1,427 to £1,537 (under review).

Application forms and further details from Appointments Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel. 01-549 1366. (743)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH

(Ref: CH/123/A1)

Applications are invited for an S.R.C. Postdoctoral Assistant to join a research group concerned with the dynamical properties of liquids and solutions. The project involves a study of molecular motion in liquids by computer simulation of molecular dynamics. Applicants should have experience in a related area of chemistry, physics or mathematics and also experience with computer programming. The appointment will be for up to two years with a minimum starting salary of £2,118 per annum, plus F.S.S.U.

Applications, including a curriculum vitae and the names of two referees, should be sent to the Registrar, U.M.I.S.T., Manchester M60 1QD to arrive not later than September 7, 1974. (719)

MEDICAL RESEARCH COUNCIL VIROLOGY UNIT INSTITUTE OF VIROLOGY UNIVERSITY OF GLASGOW

Applications are invited from post-doctoral graduates in biology, cell biology, biophysical, genetics or microbiology to join a research group concerned with human adenovirus genetics and oncogenicity. Experience in virus genetics or animal cell culture is not a prerequisite, but would be an advantage. The post is tenable for a period of three years from October 1, 1974 and the salary will start at an appropriate point on the Grade II scale (expected range from October 1974 — £2,019 to £3,636 per annum) F.S.S.U.

Applicants should send a Curriculum Vitae giving full details of qualifications and experience, and the names of three referees to Professor J. H. Subak-Sharpe, Institute of Virology, University of Glasgow, Glasgow G11 5JR by September 20, 1974. (727)

UNIVERSITY OF NEWCASTLE UPON TYNE MICROBIOLOGICAL CHEMISTRY RESEARCH LABORATORY

Applications are invited for the position of Research Associate in this unit which is concerned with chemical and biochemical aspects of bacterial cell walls and membranes. Applicants should possess a Ph.D. or equivalent qualification. The work involves a study of the mechanism of biosynthesis of teichoic acids and related compounds in bacterial membranes under the direction of Professor J. Baddiley, F.R.S. Experience in most aspects of biosynthesis, enzymology or microbial biochemistry would be appropriate. The position which is supported by the Science Research Council is for three years and is in the salary range £2,118 to £2,412 with F.S.S.U. and is available from October 1 or as soon thereafter as convenient.

Applications should be made to Professor J. Baddiley, Microbiological Chemistry Research Laboratory, The University, Newcastle upon Tyne NE1 7RU, giving full particulars and the names of two referees. (731)

DORSET AREA HEALTH AUTHORITY

EAST DORSET HEALTH CARE DISTRICT

SENIOR CHIEF TECHNICIAN

IN BIOCHEMISTRY

A vacancy exists for a senior chief technician in the above department (situated at Poole General Hospital).

Applicants should have a high level of experience in automated techniques, some experience of on-line computer application would be an advantage. The laboratory has a throughput of approximately 750,000 tests per annum, 95% via the automation section. The laboratory has full computer back up for on-line working of analytical equipment and data processing.

Further information and job description can be obtained from Dr. J. H. Johnstone, Consultant Biochemist, Poole 5100 ext. 474 or Mr. Butcher, Principal Chief Technician, Bournemouth 35201 ext. 351.

Application forms etc. can be obtained from the District Administrator, District Office, Royal Victoria Hospital, Shelley Road, Boscombe, Bournemouth, Dorset BH1 4HX. Closing date August 31, 1974 (716)

Senior Microbiologist Tate & Lyle Research Centre Reading University

A Microbial Cell Physiologist is required to work in an established multi-disciplinary team conducting basic and development studies into the biosynthesis of bacterial metabolites. Tate & Lyle group research and development, sited within Reading University Campus, enjoys active participation in university activities and has excellent research facilities, including fully instrumented fermentation equipment.

Applicants must possess a PhD. Expertise in a field of appropriate research together with an interest in the genetic and physiological control of metabolite production by micro-organisms would be an advantage.

Competitive starting salary is negotiable and excellent fringe benefits are provided. Career prospects include opportunities both in research and commercial fields.

If interested, please write describing past research and future aspirations both in terms of research and personal development to:

Group Management Services Dept
(Ref N)
Tate & Lyle Limited,
21 Mincing Lane
London EC3R 7QY

(748)

UNIVERSITY OF NEWCASTLE UPON TYNE ELECTROCHEMISTRY RESEARCH LABORATORIES

RESEARCH ASSOCIATE

A post-doctoral Research Associate is required to work on the evaluation, and further development of a range of novel ion sensitive electrodes. The successful applicant will join an established group under the direction of Dr. J. V. Dobson. An electrochemical background is desirable.

A wide range of equipment, including facilities for working at elevated temperatures and pressures is available.

The appointment is for two years commencing in the Autumn of 1974 and is in the salary range £2,118 to £2,412 depending on age and experience.

Applications or requests for further information should be sent to Dr. T. Dickinson, Department of Physical Chemistry, The University, Newcastle upon Tyne NE1 7RU. (732)

MEDICAL RESEARCH COUNCIL

Laboratory Animals Centre

Senior Technical Post

Application are invited for post of Senior Technician (Animal) in charge of Isolation Area of the Laboratory Animals Centre, which includes Germ-Free Unit, quarantine room, sheep and goats and experimental animals. This interesting and varied post requires a Fellow of I.A.T. with experience in germ-free technology, a wide knowledge of animal husbandry techniques and the management of staff. Ability to liaise with staff of all levels essential.

Salary range £2,220 to £3,021 plus £126 London Weighting; 4 weeks annual leave plus official holidays; Superannuable post; social club.

Apply to Chief Technician's Office, Medical Research Council, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4HF. (721)

UNIVERSITY OF NEWCASTLE UPON TYNE ELECTROCHEMISTRY RESEARCH LABORATORIES INORGANIC/STRUCTURAL CHEMIST

A post-doctoral Research Associate is required to work on the preparation and characterisation of ionically-conducting solids. The successful applicant would join an existing group investigating the electrochemical properties of solid electrolytes. A wide range of experimental facilities are available.

The appointment is for two years commencing in the Autumn 1974 and is in the salary range £2,118 to £2,412 depending on age and experience.

Applications or requests for further particulars should be sent to Dr. T. Dickinson, Department of Physical Chemistry, The University, Newcastle upon Tyne NE1 7RU. (733)

UNIVERSITY OF NEWCASTLE UPON TYNE ELECTROCHEMISTRY RESEARCH LABORATORIES

JUNIOR RESEARCH ASSOCIATE

A Junior Research Associate is required to work on a variety of novel electroanalytical devices. The successful applicant will join an existing group under the direction of Dr. J. V. Dobson which is developing electrochemical techniques for the analysis of gases and solutions.

Preference will be given to applicants possessing some knowledge of electronics and being prepared to learn to operate simple machine tools and assist in the experimental work.

The appointment is for an initial period of one year, as from autumn of 1974, but is renewable for at least a further two years. A salary of £1,569 by £81 is payable.

Applications or requests for further information should be sent to Dr. T. Dickinson, Department of Physical Chemistry, The University, Newcastle upon Tyne NE1 7RU. (735)

UNIVERSITY OF DUNDEE

Department of Biological Sciences

Applications are invited from Honours graduates in Botany, Biology, Agriculture or a related discipline for a post as

RESEARCH ASSISTANT

for work on an investigation of the contribution of Myrica to the nitrogen economy of natural ecosystems.

The project is supported by a N.E.R.C. grant and the post is available for three years. The salary will be in the region of £1,500 per annum.

Further information is available from Dr J. I. Sprent of the Department of Biological Sciences. Applications, quoting reference Est/51/74, and including the names of two referees, should be sent to: The Secretary, The University, Dundee DD1 4HN as soon as possible. (744)

UNIVERSITY OF NOTTINGHAM

FACULTY OF AGRICULTURAL SCIENCE

Applications are invited from suitably qualified graduates for the position of **DEMONSTRATOR IN ANIMAL PHYSIOLOGY** in the Department of Physiology and Environmental Studies.

Duties include assistance in practical and tutorial classes in animal physiology. The person appointed will be required to participate, under the supervision of Dr. T. B. Mepham, in a research project on the control of metabolism in the lactating mammary gland, using isolated perfused gland preparations. Where appropriate the person appointed will be expected to register for a higher degree.

The salary will be within the range £1,611 to £1,758 per annum. Applications by letter to the Staff Appointments Officer, University of Nottingham, University Park, Nottingham, quoting the names of two referees. Closing date, August 31. (736)

THE CITY UNIVERSITY

DEPARTMENT OF CHEMISTRY

S.R.C. RESEARCH TECHNICIAN

A Technician is required in Organic Chemistry to assist in an investigation into the 'Mechanism of Aromatic Sulphonation in Aqueous Sulphuric Acid', a project supported by the S.R.C. for three years from October 1, 1974.

Initial salary up to £1,704 per annum plus £228 London Allowance depending on age, qualifications and experience.

Application with names of two referees, as soon as possible, to: Dr R. G. Coombes, Department of Chemistry, The City University, St John Street, London EC1V 4PB. (739)

North East London Polytechnic

Department of Applied Biology

Applications are invited for the post of:

Senior Lecturer in Pharmacology

The successful applicant will be responsible for the first year of the two year part-time MSc course (CNA). He will also be required to teach on the BSc Applied Biology course (CNA). Applicants should possess a good honours degree in a suitable specialism (Pharmacology, Physiology, Biochemistry or Pharmacy), and have had extensive post-graduate experience.

Salary scale:

Senior Lecturer £3,643 to £4,330

Further details and application form from:

The Academic Staffing Officer,
Ref. S/CF 131
North East London Polytechnic,
Forest Road, London E17 4JB.
Tel: 01-527 2272.

for return by: August 30, 1974. (742)

Veterinarian for Mastitis Research

Applications are invited for an established post in the Veterinary Research Laboratories of the Department of Agriculture at Stormont.

Applicants should hold a Veterinary degree. Some postgraduate experience in practice and laboratory work would be an advantage.

The successful candidate will be specially assigned to work on mastitis in cattle. Collaborative research opportunities are available and educational and field extension work will be required.

The salary scale is:

Veterinary Research Officer (Grade II)—£2,852 to £3,610

Veterinary Research Officer (Grade I)—£3,610 to £4,365

Grading and starting salary will be related to qualifications and experience. And a cost of living supplement is payable.

Please write or telephone for an application form and further information, quoting Ref. SB 215/74/N to Civil Service Commission, Clarendon House, Adelaide Street Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned to arrive not later September 10, 1974.

DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

Applications are invited from suitably qualified persons for the following posts:-

- LABORATORY TECHNICIAN—BIOCHEMISTRY**
Grade 4. £1,848 to £2,163 per annum.
To assist research involving chemical synthesis and evaluation of novel compounds and to assist with undergraduate practical classes. Ref: 274/T/NA.
- LABORATORY TECHNICIAN—BIOCHEMISTRY/MICROBIOLOGY**
Grade 4. £1,848 to £2,163 per annum.
To be responsible for technical support to medical and science undergraduate Biochemistry/Microbiology classes and provide some support for related research. Ref: 275/T/NA.
- LABORATORY TECHNICIAN—PHARMACOLOGY**
Grade 3. £1,650 to £1,920 or Grade 4. £1,848 to £2,163 per annum, according to qualifications and experience.
To provide technical support for Science undergraduate Pharmacology/Mammalian Physiology classes and research. Ref: 276/T/NA.
- PHOTOGRAPHIC/REPROGRAPHIC TECHNICIAN**
Grade 3. £1,650 to £1,920 or Grade 4. £1,848 to £2,163 per annum.
To provide a departmental photographic service, to produce slides, and to prepare diagrams, graphs and illustrations. Ref: 277/T/NA.
- LABORATORY TECHNICIAN—RADIOISOTOPIC SERVICES**
Grade 3. £1,650 to £1,920 per annum.
To be primarily responsible for radioisotopic facilities in the Analytical Services Unit. Experience of instrumentation and/or chemistry/biochemistry. Ref: 279/T/NA.
- ELECTRON MICROSCOPY TECHNICIAN**
Grade 2B. £1,524 to £1,794 per annum.
To join a unit providing Electron microscopy services. Some experience of E.M. work and/or histology. Ref: 281/T/NA.

Cost of living allowance currently £2.40 per week payable in addition to salary shown.

Posts 1-4: Related experience, an appropriate qualification (minimum O.N.C. or equivalent) and enthusiasm are required for these established appointments. Graduates in appropriate disciplines are welcome to apply for posts 1-3.

Posts 5-6: Minimum qualification for these posts O.N.C. or equivalent in appropriate subjects.

Applications giving details of age, qualifications and experience and the names of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting appropriate reference number. (730)

ROYAL POSTGRADUATE
MEDICAL SCHOOL
JUNIOR TECHNICIAN

required in a Biochemistry Laboratory. Post suitable for candidate attempting entrance to university in 1975. Other candidates holding GCE "O" levels in Maths, English and two Science subjects will also be considered. Day release available for further study. Salary according to age and qualifications. Applications to the Secretary, RPMS, Hammersmith Hospital, DuCane Road London W12 0HS, quoting ref. no. 2/146N. (712)

ROYAL POSTGRADUATE
MEDICAL SCHOOL
JUNIOR TECHNICIANS
(2 Posts)

required from October 1, 1974 to assist with research into muscle diseases. Posts suitable for School Leaver holding a minimum of GCE "O" level passes in English, Maths and two science subjects.

Salary according to age and qualifications. Applications to the Secretary, RPMS, Hammersmith Hospital, DuCane Road, London W12 0HS, quoting ref. no. 6/254N. (711)

NEW ZEALAND
DEPARTMENT OF SCIENTIFIC AND
INDUSTRIAL RESEARCH

The Applied Biochemistry Division of the Department of Scientific and Industrial Research, Palmerston North has a vacancy for a mycologist-fermentation scientist in the carbohydrate research group. The group is involved in research on the production of mould extracellular enzymes and their use in the degradation of wood waste, and would also aim to contribute to a more fundamental study of the lignin-carbohydrate relationship in plant cell walls.

Qualifications: Ph.D with 2-3 years research experience, and with a sound knowledge of fungi.
Salary: Up to NZ\$9,339 p.a. dependent on qualifications and experience.

Passages: Fares for appointee and his immediate family, will be paid.

Incidental expenses: Up to NZ\$120 for a single man and NZ\$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, SW1Y 4TQ, with whom applications will close on September 16, 1974.

Please quote reference P/T 116 when enquiring. (714)

NATIONAL INSTITUTE FOR
BIOLOGICAL STANDARDS
AND CONTROL

HAMPSTEAD, LONDON NW3 6RB

Medical or post-doctoral biochemistry graduate needed in Division of Hormones and Blood Products to help in setting up W.H.O. and other reference standards for certain substances important in medicine, including peptide hormones, which are estimated by radioimmunoassay.

The work involves wide collaboration with scientists in a variety of disciplines. There are excellent opportunities for research.

Appointment on M.R.C. salary scale for non-clinical scientific staff £1,830 to £3,708 plus London Weighting £162 p.a. University or N.H.S. superannuation.

Further information available on request to the Institute.

Applications, addressed to the Director of the Institute, should arrive by the end of September 1974. (745)

MEAT RESEARCH INSTITUTE
BACTERIOLOGIST

required to study the origin, spread and survival of salmonellae and other food-poisoning organisms which may contaminate carcass meat, and improve methods for their demonstration and recovery. The successful applicant will also be expected to participate in an established programme of research on factors which inhibit u.v. growth of bacteria.

Salary range: Scientific Officer £1,592 rising to £2,675; Higher Scientific Officer £2,461 rising to £3,371. There is a non-contributory superannuation scheme.

Applicants will be expected to have a first or upper second class honours degree. Starting salary according to qualifications and experience but for entry to the H.S.O. scale, applicants must have at least two years postgraduate research experience.

Application forms, Secretary, Meat Research Institute, Langford, Bristol BS18 7DY. (741)

Pharmaceuticals
Division

Information
Scientist

Applications are invited for a Science Graduate to join a team providing current awareness and information retrieval services to research scientists. The applicant should have a sound knowledge of organic chemistry. A reading knowledge of German would be an advantage.

Mechanised information systems are in operation.

Previous experience is not essential, but the successful applicant must be prepared to meet the challenge of mechanisation in information work and also show a keen interest in the pharmaceuticals industry.

Pharmaceuticals Division is attractively situated in rural North Cheshire within easy reach of main road and rail routes. Conditions of service, career opportunities and assistance given to married men in moving home are designed to attract and retain staff of high calibre.

Please write, asking for an application form to:

Miss K E Webster, Personnel Officer
ICI Pharmaceuticals Division
Mereseid, Alderley Park,
Nr. Macclesfield, Cheshire.

UNIVERSITY OF LONDON
CHARING CROSS HOSPITAL
MEDICAL SCHOOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited from graduates in science or medicine for a research post (17 months initially but probably continuing) to join a group working on the possible use of lipid vesicles (liposomes) in drug administration and in enzyme replacement therapy in disease. The applicant should be under 30 years; salary according to age and qualifications but on the lectureship scale. Experience in the field of tissue culture would be an advantage. The group is based in the new laboratories of Charing Cross Hospital Medical School in Fulham.

Applicants should send a curriculum vitae and the names of two referees as soon as possible to Professor Brenda E. Rymann, Department of Biochemistry, Charing Cross Hospital Medical School, Fulham Palace Road, London, W6 8RF.

(718)

THE GRASSLAND RESEARCH
INSTITUTE

MURLEY, MAIDENHEAD BERKSHIRE
SCIENTIFIC OFFICER/HIGHER
SCIENTIFIC OFFICER

is required in the AGRONOMY DEPARTMENT to assist with husbandry investigations on the yield and quality of grass and forage crops, with particular relevance to the efficiency and nitrogen usage and/or the management of grass/legume mixtures.

Minimum qualifications:—Pass degree or equivalent in agriculture or a relevant science and preferably experience of field and laboratory investigation on grassland plants.

Salary: Scientific Officer £1,592 to £2,675 per annum; Higher Scientific Officer £2,461 to £3,371 per annum, plus cost of living supplement.

At least 5 years post graduate experience will be required for appointment in the higher grade. There is a non-contributory Superannuation Scheme.

Applications to the Secretary by September 30, 1974, giving curriculum vitae and the names of three referees. Reference 2/1/2.

(740)

UNIVERSITY COLLEGE GALWAY
JUNIOR LECTURESHIP IN BOTANY

Applications are invited for the above post. Salary scale £2,478 by 99 (10) to £3,468 p.a. plus Family Allowances. Applications will be particularly welcome from candidates with a specialised knowledge of Irish vegetational history.

The closing date for receipt of applications is **September 12, 1974**. Prior to application, further information should be obtained from the Registrar of the College.

(738)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY
EXPERIMENTAL OFFICER

Applications are invited for the above post (financed by the Science Research Council) to work with a group on some aspects of Affinity Chromatography. Applicants should hold a good honours degree in Chemistry or Biochemistry, and have experience in either nucleotide chemistry or enzymology. The appointment will be on the scale £1,764 to £2,553 per annum, and it is hoped that the successful applicant will take up the post by October 1, 1974.

Application forms may be obtained from the Registrar, The University of Liverpool, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276175.

(766)

UNIVERSITY OF SYDNEY
LECTURESHIP/SENIOR
LECTURESHIP IN BIOCHEMISTRY

Preference to candidates with teaching and research experience in fields of metabolism of animal tissues.

The position advertised is a permanent one, but it may be filled at the Lectureship level for three years in the first instance, with possibility of permanency after that time or in certain cases return fares.

Salary ranges—Lecturer: \$A9,002 to \$A12,352 p.a.; Senior Lecturer: \$A12,643 to \$A14,724 p.a. Applications, including curriculum vitae, list of publications and names of three referees, by September 16, 1974 to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information is available. Further information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

(764)

AUSTRALIAN ATOMIC ENERGY COMMISSION
RESEARCH ESTABLISHMENT

Lucas Heights—near Sydney

Deputy Controller Safety

An experienced safety specialist is required to fill the position of Deputy Controller Safety within the Safety Section of the Australian Atomic Energy Commission Research Establishment, Lucas Heights, N.S.W., Australia. The Safety Section covers a broad spectrum of safety activities including:—

- radiological protection,
- critically safety,
- reactor safety,
- non-ionising radiation protection,
- industrial safety.

This is a senior position and the appointee will be expected to have had a number of years of relevant safety experience and to have a strong interest in safety management. He will be required to assist in the management of the Safety Section, to undertake specific work in one or more of the above mentioned safety activities and to maintain a broad interest in the others.

The minimum qualifications required are a University degree or diploma of a standard acceptable to the Commission. It is anticipated that an appointment will be made within the grade of Scientific Services Officer, Class IV, \$A13,299 to \$A14,202, but an appointment to a higher grade will be considered for an applicant who is better qualified and more experienced than envisaged in this advertisement.

Application forms may be obtained by writing to the Counsellor (Atomic Energy), Australian High Commission, Canberra House, 10-16 Maltravers Street, London WC2R 3EH.

(754)

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS

Applications are invited for a Post-Doctoral Research Assistantship beginning October 1974. The research programme, directed by Dr. D. L. Weaire, is the study of structural models of Amorphous Solids, and involves the use of computational methods.

The appointment is funded by the Science Research Council, and is for a period of three years.

Commencing salary not more than £2,118 per annum.

Applications, consisting of a brief curriculum vitae and the names of two referees, should be sent to Professor Harpe, Department of Physics, Heriot-Watt University, Riccarton, Currie, Midlothian, EH14 4AS. (757)

HERIOT-WATT UNIVERSITY
DEPARTMENT OF CHEMISTRY

Post-Doctoral Research Assistantship

Applications are invited for a Post-Doctoral Research Assistantship, sponsored by the Science Research Council, to study photochemistry in the vacuum ultraviolet region in collaboration with Dr. P. John. The appointment is tenable for two years, commencing October 1, 1974. The salary will be in the range £2,247 to £2,412, plus F.S.S.U.

Applications consisting of a brief curriculum vitae and the names of two referees, should be sent to Dr. P. John, Department of Chemistry, Heriot-Watt University, Riccarton, Currie, Edinburgh EH14 4AS. (758)

NORTHERN RIVERS COLLEGE OF ADVANCED EDUCATION LISMORE, N.S.W., AUSTRALIA

The Northern Rivers College of Advanced Education is a multi-purpose institution located in Lismore, on the far north coast of New South Wales.

The college is temporarily housed in the form of Lismore High School Building, adjacent to the business section, whilst new buildings are to be erected on a site of over 100 acres at Lismore Heights on the outskirts of the city.

The College has three schools; Teacher Education, Business Education, and recently the Department of Cultural and Scientific Studies has been upgraded to a School.

Applications are now invited for the following positions:-

SCHOOL OF CULTURAL AND SCIENTIFIC STUDIES

PRINCIPAL LECTURER

The successful applicant will be expected to encourage the development of programmes within the School, continue negotiation on the possibilities of transfer courses in Engineering and possibly Science, with a large metropolitan tertiary institution and maintain service courses for the School of Teacher Education and the School of Business Education.

The applicant, as well as having the academic background of leadership in tertiary work, should also have the appropriate qualifications in the Physical Sciences or allied fields. It is expected, although not essential, that a Doctoral Degree would be the minimum academic qualification.

SALARY: \$A15,744 range \$A16,389

SCHOOL OF TEACHER EDUCATION

PRINCIPAL LECTURER

EARLY CHILDHOOD EDUCATION

This position requires a person with appropriate academic qualifications and training and experience in Early Childhood Education, with an understanding of developmental needs of children in child care centres as well as in pre-school centres. It is expected that applicants training and experience should cover the childhood area from 2 to 8.

The successful applicant would be working mainly within the School of Teacher Education, contributing where appropriate to present courses and would be involved in planning and innovating the educational area related to children of early age.

It may also be expected that such a lecturer would initiate the planning of a proposed new school related to this age group to be established in due course.

SALARY: \$A15,744 range \$A16,389

SCHOOL OF CULTURAL AND SCIENTIFIC STUDIES

SENIOR LECTURER

A vacancy will exist at the beginning of 1975 for a Senior Lecturer with academic qualifications in Government, Public Administration, Management and Urban Affairs. This Senior Lecturer will be required to assist the Head of the School in co-ordinating the work and development of the School and to co-operate with other schools by providing courses for their students.

Assistance in the development of the academic reputation of the College will also be required.

SALARY: \$A12,643 range \$A14,724

SCHOOL OF BUSINESS EDUCATION

SENIOR LECTURER

DATA PROCESSING

The successful applicant would need minimum qualifications, Degree or Diploma in a relevant area with experience in programming several languages. Lecturing experience is desirable and marketing as a major area would be an advantage. It is anticipated that the initial semester unit for 1975 will provide for over 60 students and the applicants will be required to develop courses in programming and system analysis.

A Wang Mini Computer configuration will be used initially, with a Main Frame P.D.P. 11/45 planned within the new building programming in the tri-ennium.

SALARY: \$A9,002 range \$A12,352.

The successful applicants will be appointed as employees of the College. Conditions of employment are similar to those enjoyed in Universities and Colleges of Advanced Education, and include four weeks' recreation leave annually and sick leave, with a staff Housing Scheme available.

Provision exists for the granting of study leave after suitable periods of service, and access is available to the N.S.W. State Superannuation Scheme, subject to certain conditions.

Assistance is available to persons residing outside Lismore N.S.W. towards removal expenses.

Applications stating age, qualifications, experience, marital status, and the names and addresses of three referees, together with a recent photograph, should be lodged with the undersigned by Thursday, September 14, 1974.

Postal applications should be sent to P.O. Box 157, Lismore, N.S.W. 2480.

I. D. K. WREN

SECRETARY.

(768)

CENTRAL PUBLIC HEALTH LABORATORY

Honours Science Graduate required by the Standards Laboratory for Serological reagents for work with viral diagnostic reagents.

Applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London, NW9 5HT. (749)

SEALE-HAYNE COLLEGE LECTURER IN ANIMAL PRODUCTION

Applications are invited for the above appointment. The salary will be based on the Lecturer Grade I or II Scales. Further details may be obtained from and applications should be sent to: The Principal, Seale-Hayne College, Newton Abbot, Devon. (750)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSICS

Applications are invited for a Postdoctoral research appointment in theoretical physics, available from October 1, 1974. The successful applicant will work on the theory of the electronic structure of liquid metals under the supervision of Professor J. L. Beeby. Previous experience in many-body theory or solid state theory is desirable. The salary will be in the range £2,118 to £2,580. For application forms or further details please write to: Professor J. L. Beeby, Dept. of Physics, University of Leicester, Leicester LE1 7RH. (752)

SENIOR BIOCHEMIST

A leading British pharmaceutical research organisation has a vacancy for a SENIOR BIOCHEMIST with a few years postdoctoral experience to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for an Application Form from The Secretary, Biorex Laboratories Limited, Biorex House, Canonbury Villas, London N1 2HB. (759)

RESEARCH ASSISTANT required to work on radioimmunoassay in the Department of Obstetrics and Gynaecology. The post is funded by the International Planned Parenthood Federation and the successful applicant would continue the work for the Federation which is carried out in the departmental laboratories. The balance of the work planned would enable a suitably qualified person (1st or 2nd class honours degree) to register for a Ph.D. in the University of London. Salary £1,797 to £2,259 plus London Weighting. Apply in writing with curriculum vitae to the Secretary, University College Hospital Medical School, University Street, London, W.C.1. (753)

UNIVERSITY OF LONDON KING'S COLLEGE DEPARTMENT OF PHYSIOLOGY

Applications are invited for two posts of lecturer in Physiology. The Department of Physiology is engaged in teaching medical, dental and science students and has a rapidly expanding research programme especially in the areas of membrane transport and electrophysiology. Applicants should have an active research interest either in one of these areas or in some other aspect of basic physiology including such interdisciplinary fields as genetic, development, or behavioural physiology. A medical qualification although desirable is not essential.

Salary Scale £2,118 to £4,896 per annum plus £213 London allowance p.a. The starting salary will be at an appropriate point on the scale F.S.S.U. benefits will be payable.

Application forms and conditions of appointment are available from the Registrar, University of London, King's College, Strand, London WC2R 2LS and should be returned to him by September 21, 1974. Quoting reference N16/8. (755)

STATE OF KUWAIT Kuwait University Administration Department

NOTICE

Applications are invited for the following posts for the academic year 1974/1975:-

1. Laboratory Technician at the Geology Museum of the Faculty of Science with a B.Sc. degree and not less than three years experience in this field.
2. Chief Laboratory Technician (male, married) required to take charge of teaching and research laboratories of an expanding Department of Zoology. The successful candidate will be highly experienced and preferably a Fellow of the Institute of Medical Laboratory Technicians (F.I.M.L.T.).
3. Chief Animal Technician (male, married) required to take charge of small Animal Unit in the Department of Zoology. The candidate should be highly experienced and preferably a Fellow or Associate of the Institute of Animal Technicians (F.I.A.T. or A.I.A.T.).
4. Senior Technician or Technician required to join a newly established Immunology Unit in the Department of Zoology. Experience in general immunological and/or tissue culture techniques preferred.
5. Laboratory Technician in educational methods for the Department of Education with a degree from a recognized college or institute majoring in technical education (painting and handicraft) and educational methods. Applicants must have a good command of English.
6. Supervisor in audio-visual methods for the English Language Center. Applicants must be qualified with a diploma or M.A. degree in T.E.F.L. as well as majoring in educational methods with enough experience.

Salaries commence at a minimum of K.D. 200/- per month (tax free), according to qualifications and experience. K.D. = \$2.90.

Applications should be addressed to Kuwait University, Kuwait, with photostatic copies of the academic qualifications and experience, including all details pertaining to the post applied for, present employment and salary, aside from full address of each applicant.

Deadline for all applications is September 5, 1974.

(765)

POSTDOCTORAL RESEARCH ASSISTANT IN ORGANIC CHEMISTRY

Applications are invited from research workers with experience in organic chemistry for a post-doctoral research assistantship. The appointment is for three years, salary on M.R.C. scale (£2,058 by £165 to £2,388). The work is in collaboration with Dr. A. J. Kirby and Dr. D. M. Blow and will involve the synthesis of phosphonate analogues of oligopeptides for evaluation as enzyme inhibitors. Applications, with curriculum vitae and the names of two referees, to Dr. S. G. Warren, University Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW. (767)

UNIVERSITY OF IBADAN NIGERIA

Applications are invited for the following posts in the Faculty of Medicine:

LECTURER IN NUTRITIONAL BIOCHEMISTRY

in the Department of Biochemistry. Applicants should hold a Ph.D. in the general field of Human Nutrition.

Salary scales: Lecturer (Proclinical) N2,760 to N4,830 p.a. (£1 sterling = N1.46). The British Expatriates Supplementation Scheme is unlikely to be applied to this appointment. Family passages; various allowances; superannuation scheme; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than September 12, 1974 to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (772)

UNIVERSITY OF READING

Research Assistant required in Department of Microbiology to work on the preparation and properties of a ribosomal vaccine derived from Bordetella Pertussis. The project will involve a study of both humoral and cellular responses to the vaccine. Salary from £1,616 or the equivalent of a Research Council Studentship if the candidate is accepted for a higher degree. The project is supported by Medical Research Council funds. Applicants, who should be graduates with a 1st or 2nd Class Honours degree in Microbiology or a related subject, should apply to Dr A. I. Tiffin, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ, giving a brief curriculum vitae and the names of two referees. (Ref. MM41). (777)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

PLANT PATHOLOGIST

required to measure the prevalence, dispersal and effects of splash dispersed pathogens, particularly those attacking cereals in reduced cultivation systems.

Appointment in grade of Higher Scientific Officer £2,461 to £3,371 or Senior Scientific Officer £3,157 to £4,441 (minimum qualifications: 1st or upper 2nd class honours degree and not less than 2 years' appropriate post-graduate experience, or 4 years for S.S.O.). There is a non-contributory superannuation scheme.

Applications, with names of two referees and quoting Ref. No. 234 to the Secretary by September 9, 1974. (779)

Guy's Hospital

Department of Clinical Physics
and Bioengineering

Electronic Engineer or Physicist—Senior Grade

Applications are invited from engineering and physics graduates with not less than four years postgraduate experience in applied electronics research. The successful applicant will be expected to become involved in the development of new measurement techniques in a variety of clinical situations. A knowledge of digital circuit and/or computer methods would be an advantage. Excellent facilities in new department. Salary Scale £2,964 to £3,843 plus London Weighting plus Threshold Allowance.

Electronics Technician/ Engineer Medical Physics Grade III

Applications are invited for the post of Electronics Technician/Engineer to join a small team engaged upon the maintenance, repair, and calibration of a wide range of electromedical equipment.

Candidates should have an O.N.C., H.N.C. or equivalent in electronics with at least three years experience in maintenance and servicing of electronic instruments. Salary Scale £1,719 to £2,211 plus London Weighting plus Threshold Allowance.

Application Forms available from the Personnel Officer, Guy's Hospital, St. Thomas Street, London SE1 9RT. Telephone 01-407 3662 Ext. 68. (770)

UNIVERSITY OF READING TECHNICIAN (Grade 5)

required for Media and Glassware Preparation Unit in the Plant Science Laboratories. Experience in the preparation of complex media and administrative competence required. Applicants should have H.N.C./Degree in Microbiology or related subjects. Salary scale £2,007/£2,382 p.a. Apply in writing quoting Ref: T.N.69 to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. (776)

CONSERVATION OFFICER SUSSEX TRUST FOR NATURE CONSERVATION

has vacancy at a starting salary of £1,800 to £2,200 p.a. Car ownership essential. Applications by September 7 to, and for further information from: The Hon. Secretary Woods Mill Henfield, Sussex. (783)

UNIVERSITY OF NEWCASTLE UPON TYNE TEMPORARY LECTURESHIP IN PSYCHOLOGY

Applications are invited for the above post, tenable from a date as soon as possible until July 31, 1977, in the Department of Psychology. The department is especially interested in persons whose interests are in the field of Personality; but suitable candidates with other interests should not be dissuaded from applying.

It is expected that an appointment will be made in the lower part of the scale £2,118 to £4,896 according to age, qualifications and experience. Membership of F.S.S.U. required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne NE1 7RU with whom applications (3 copies) together with the names and addresses of three referees should be lodged not later than September 9, 1974. Please quote reference N. (787)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

DEPARTMENT OF MEDICAL
MICROBIOLOGY

RESEARCH ASSISTANT

required in the above Department for an investigation into the biochemistry of meconium in connection with Cystic Fibrosis. Candidates should have a Degree in Biochemistry or an allied science. The appointment will commence in October, 1974 and will be for three years; salary on the scale for Junior Scientific Officers (£1,497 to £2,259). Applications, with a brief curriculum vitae and the names and addresses of two referees to the Registrar, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN from whom further particulars are available. (788)

UNIVERSITY OF GLASGOW

DENTAL HOSPITAL AND SCHOOL

RESEARCH ASSISTANTSHIP IN DENTAL BIOCHEMISTRY

Applications are invited for a RESEARCH ASSISTANTSHIP IN DENTAL BIOCHEMISTRY, tenable for a period of up to four years from October 1974.

Candidates should have an Honours Degree in Biochemistry, Microbiology or an allied subject. There will be an opportunity to apply to register for a higher degree.

The work will be mainly concerned with the synthesis of glucans by extracellular bacterial enzymes.

Salary scale £1,500 by £75 to £1,725. F.S.S.U.

Applications, including curriculum vitae and names of two referees, should be sent to Dr J. A. Beeley, University of Glasgow Dental School, 378 Sauchiehall Street, Glasgow G2 3JZ, from whom further information may be obtained.

In reply please quote Ref. No. 3527M. (792)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of (a) PROFESSOR or (b) SENIOR LECTURER IN CROP PROTECTION in the School of Agricultural Sciences. Candidates should possess a higher degree, extensive teaching experience to undergraduate and postgraduate students, extensive research preferably related to problems of tropical agriculture and experience in academic administration and extra-curricular activities. Appointee will be expected to teach the basic course in Crop Protection which consists of lectures and practicals in Entomology, Plant Pathology and Nematology. For this reason, a broad background of training and experience is necessary. Research interests can be in any Crop Protection discipline, but applicants should be able to carry out field orientated investigations leading to the protection and increased production of Zambian agricultural crops.

Salary scales: Professor K7,400 to K7,800 p.a. Senior Lecturer K5,600 to K6,600 p.a. (£1 sterling = K1.53). The British Government may supplement salary in range £954 to £1,152 p.a. (sterling) for married appointees or £78 to £204 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by air mail, not later than September 5, 1974 to the Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars of these appointments may be obtained from either address. (791)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF MICROBIOLOGY

TUTORIAL ASSISTANTSHIP

Applications are invited for a S.R.C. Postgraduate Tutorial Assistantship for work on the synthesis of inducible, membrane-bound, respiratory enzymes in bacteria. Preference will be given to candidates with biochemical qualifications. The appointment will be for two years only in the salary range £1,500 to £1,581 per annum.

Applications, giving a brief curriculum vitae and the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0627. Closing date September 13. (790)

UNIVERSITY OF ABERDEEN

RESEARCH ASSISTANT IN PHYSIOLOGY

Applications are invited for above post in **Invertebrate Physiology** to work on either invertebrate behaviour under high pressure or the cytology of invertebrate neurones under high pressure. The post offers wide opportunities for research to a suitable graduate; no experience of high pressure methods is required.

Salary in range £1,494 per annum by 87 to £1,668. Appointment is supported by the S.R.C. for three years.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by August 30, 1974. (785)

GLASSHOUSE CROPS RESEARCH INSTITUTE

requires

SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER

in

MICROBIOLOGY DEPARTMENT

for work on nutrition and growth of mushrooms. Applicants should have degree or equivalent qualification in microbiology, botany or biochemistry. Practical experience in Microbiology or biochemistry an advantage.

Salary within scale £1,592 to £2,675 (S.O.) or £2,461 to £3,371 (H.S.O.) according to qualifications and experience. Contributory superannuation scheme with additional allowance of 5½% of gross salary to offset contributions.

Further particulars from Secretary of the Institute, Worthing Road, Rustington, Littlehampton, Sussex, to whom applications giving full biographical details and names and addresses of two referees should be sent by September 12. Please quote N84. (784)

UNIVERSITY OF LEEDS ASTBURY DEPARTMENT OF BIOPHYSICS

Applications are invited from suitable qualified physical chemists or physicists for a Postdoctoral Research Assistantship to investigate the Light Scattering Rayleigh Line-width of Gelling Systems. The appointment will be for one year in the first instance at a salary of £2,118 to £2,247 with F.S.S.U., depending upon age and experience. Candidates should have an interest in the general field of polymers. Applications giving a brief Curriculum vitae, etc., and naming two referees, should be sent as soon as possible to Dr D. B. Sellen, Astbury Department of Biophysics, The University, Leeds LS2 9JT. (775)

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Advertisement No. 10/74

It is proposed to appoint Chief Editor in the Publications and Information Directorate, New Delhi.

Job requirements:— It is a top management post in the editorial field of Science & Technology. The duties involve overall charge of editing and production of scientific and technical journals published by the C.S.I.R. (b) building up the background information for the publication of the "Wealth of India" series; and (c) publication of monographs, reports of seminars and conferences and other scientific and technical literature.

Qualifications and Experience: Candidates should have appropriate qualifications in Science/Technology and proven literary excellence and experience of editorial work of high standard. Candidate should give evidence of competence in management of publications and their production.

Salary/Conditions of Service: The salary scale attached to the post is Rs. 1,600 by 100 to 1,900 (likely to be revised). Initial pay will be fixed according to merits. The person selected will be appointed on contract for a period of six years, which would be confirmed after an initial period of two years of satisfactory service. Other conditions of contract will be supplied on request.

Age limit: Below 50 years relaxable in special cases. Scientists/Technologists interested may obtain a standard proforma for sending their curriculum vitae from the Chief (Administration), Council of Scientific & Industrial Research, Rafi Marg, New Delhi-1. They can also obtain a brochure on the aims and objects and latest annual report of the Directorate. Completed curriculum vitae proforma must be received in this office on or before 21.8.1974.

"Canvassing in any form and/or bringing in any influence, political or otherwise, will be treated as a disqualification for the post."

THE INSTITUTE OF ORTHOPAEDICS (University of London)

Royal National Orthopaedic Hospital
234 Great Portland Street,
London W1N 6AD

Applications from graduates in either medicine or science are invited for the whole time post of

RESEARCH ASSISTANT in the Department of Morbid Anatomy

The appointment is for one year in the first instance, and is renewable annually. Salary on the appropriate scale for lecturer (£3,135 to £4,041 Clinical; £2,118 to £3,462 Non-Medical) according to qualifications and experience. Superannuation under F.S.S.U.

The post will provide opportunity for research in the general field of bone structure and bone pathology, under the supervision of Prof. H. A. Sissons. For a medically-qualified pathologist it will also provide training and experience in orthopaedic pathology. Further information can be obtained from Prof. H. A. Sissons.

Applications, together with the names of two referees, should reach the Secretary, at the above address, by September 30 1974. (798)

Soil Scientist

Applications are invited for a permanent post in the Agricultural and Food Chemistry Research Division of the Department of Agriculture. The successful candidate may be required to undertake teaching duties in the Faculty of Agriculture, The Queen's University, Belfast.

The successful candidate will join a team engaged in research and specialist advisory work in chemical, physio-chemical and physical properties of soils and soil/crop relationships.

The appointment may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level, and the qualifications required are as follows:

SSO Over 25 and under 32 years of age with a first or second class Honours Degree in Chemistry, Biochemistry, Agricultural Chemistry or Soil Science and at least 4 years postgraduate experience preferably in physio-chemical or pedological aspects of Soil Science.

HSO Under 30 years of age with an Honours Degree as above and at least 2 years relevant postgraduate experience.

SO Under 27 years of age with an Honours Degree as above.

Salary scales: SSO £3,157 to £4,441
HSO £2,461 to £3,371
SO £1,592 to £2,675

Entry point to the relevant salary scale will be related to qualifications and experience, and a cost of living supplement is payable.

Please write or telephone for an application form, quoting Ref. SB 216/74/N to the Secretary, Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned not later than September 10, 1974. (781)

**NORTHERN IRELAND
CIVIL SERVICE**

UNIVERSITY OF LEEDS DEPARTMENT OF ANIMAL PHYSIOLOGY AND NUTRITION

Applications are invited for a post of RESEARCH ASSISTANT to undertake work on the mode of action in sheep of the growth stimulating effect of long daylength. The work will involve radioimmunoassay of hormones in plasma samples taken from sheep kept in different daylengths and following various surgical and hormone treatments.

Salary equivalent to a Research Council postgraduate award.

Application forms and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 41/14/D). Closing date August 27, 1974. (774)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF BIOLOGICAL SCIENCES RESEARCH ASSISTANT

Applications are invited from graduates with interests in natural product chemistry, protein chemistry and/or biophysics to investigate the structure of certain scleroproteins of molluscan origin. The appointment is supported by the Science Research Council for a period of two years, commencing October 1, 1974, on the salary scale £1,404 to £1,509 plus F.S.S.U.

Further particulars may be obtained (quoting reference L.840/C) from the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW to whom applications (three copies), naming three referees, should be sent not later than August 31, 1974. (778)

UNIVERSITY OF SUSSEX SCHOOL OF BIOLOGICAL SCIENCES

Postdoctoral Research Assistants

required for project on:—

- The biochemical basis of plasma membrane modifications associated with cell transformation.** Experience with membrane enzymes, enzyme isolation and purification of glycolipid biochemistry would be an advantage. The project is supported by the Cancer Research Campaign, it is for one year in the first instance and is renewable. Salary will be on University Lecturer scale up to £3,400 a year according to experience and qualifications.
- The changes in the biochemistry of the cell nucleus induced by chemical carcinogens.** Experience with enzymes or with chromatin would be an advantage. The project is supported by the Cancer Research Campaign, it is for one year in the first instance and is renewable. Salary will be on University Lecturer scale up to £3,000 a year, according to experience and qualifications.

Applications for both posts with the names of three referees to Dr S. Shall, School of Biological Sciences, University of Sussex, Brighton BN1 9QG. (805)

AUSTRALIA

PUBLIC SERVICE OF VICTORIA MINISTRY FOR CONSERVATION

DIRECTOR OF ENVIRONMENTAL STUDIES

REF. NO. (Z/02)

Yearly Salary: \$A19,302.

Duties: To direct the activities of the Environmental Studies Group of the Ministry. To represent the Ministry at policy level in the formation of integrated environmental studies and in the planning and conduct of those studies.

To plan and implement the actions necessary to co-ordinate the activities of Government departments, Universities and other groups participating in such studies.

To prepare appropriate reports and advice

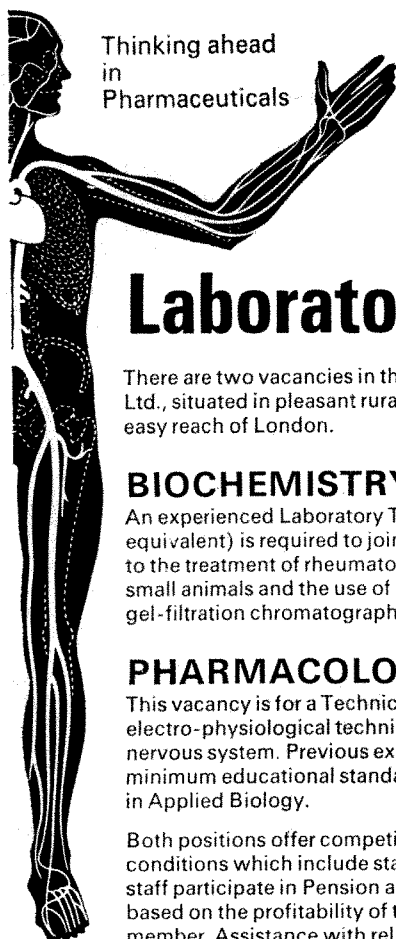

To participate in the application of research findings to multi-resource planning for environmental management.

Qualifications: A higher degree in the physical or biological sciences or in engineering, or equivalent

qualifications, and evidence of experience in more than one discipline; proven ability to initiate and supervise an integrated set of inter-disciplinary investigations required to understand the resources of a region and the constraints to be exercised in their use and management.

The applicant must have had experience or a close relationship with Government, University and Industry.

Applications quoting reference number (Z/02), should be addressed to the Secretary, Public Service Board of Victoria State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, September 25, 1974, together with statements of experience and qualifications and date and place of birth. (800)

Thinking ahead
in
Pharmaceuticals

Laboratory Technicians

There are two vacancies in the Biology Division of Allen & Hanburys Research Ltd., situated in pleasant rural surroundings in Ware, Hertfordshire, within easy reach of London.

BIOCHEMISTRY DEPARTMENT

An experienced Laboratory Technician (with H.N.C. in Applied Biology or equivalent) is required to join a team of biologists working on new approaches to the treatment of rheumatoid arthritis. The work will involve the handling of small animals and the use of biochemical laboratory techniques. Experience of gel-filtration chromatography would be a particular advantage.

PHARMACOLOGY DEPARTMENT

This vacancy is for a Technician to work with a senior graduate in developing electro-physiological techniques for evaluating drug effects on the central nervous system. Previous experience is not essential but we do require a minimum educational standard of two 'A' levels (one in Biology) or an H.N.C. in Applied Biology.

Both positions offer competitive commencing salaries and good working conditions which include staff canteen and sports and social club. Members of staff participate in Pension and Life Assurance schemes and a bonus scheme based on the profitability of the Glaxo Group of Companies of which we are a member. Assistance with relocation expenses will be given, where appropriate.

Please apply in writing to:

Ms. E. W. Smith,
Assistant Personnel Officer,
Allen & Hanburys Research Ltd.,
Ware, Herts. SG12 0DJ.

Allen & Hanburys

MAKERS OF FINE PHARMACEUTICALS

(793)

CHARING CROSS HOSPITAL MEDICAL SCHOOL (University of London)

Applications are invited from medical or other suitably qualified graduates for the post of LECTURER in the DEPARTMENT OF PHYSIOLOGY, 1974-75 session. Apply with full details of qualification and experience to the Secretary, Charing Cross Hospital Medical School, Brandenburgh House, 116 Fulham Palace Road, London W6 9HH, quoting reference PH/L. Closing date August 31, 1974. (799)

The Marie Curie Memorial Foundation

THE CHART, OXTEAD RH8 0TL

1. RESEARCH ASSISTANT FOR THE METABOLIC UNIT with a degree in Nutrition or Biochemistry and an interest in clinical research in cancer. Experience of drug metabolism would be an advantage.
2. RESEARCH ASSISTANT FOR THE BIOLOGICAL CHEMISTRY UNIT with Grad. R.I.C., or B.Sc. (Hons) in chemistry, with an interest in organic chemistry. Current projects involve the design, synthesis and evaluation of new anti-tumour agents and metabolism of anti-cancer drugs.
3. RESEARCH ASSISTANT FOR THE IMMUNOCHEMISTRY UNIT with a degree in biochemistry to investigate the role of acid hydrolases in tumour invasion and metastatic spread. Experience in immunochemical and biochemical analytical techniques would be an advantage.

Salaries are based on the Whitley Council Scale with superannuation. Successful applicants may register for a higher degree after an initial probationary period. Applications including the names of two referees and indicating the post sought should be sent to the Secretary at the above address. (802)

HEALTH AUTHORITY
BROOK GENERAL HOSPITAL
SHOOTERS HILL ROAD,
LONDON SE18 4LW

SENIOR TECHNICIANS

for modern fully automated department.
Haematology/blood group serology.

TECHNICIANS/JUNIORS

Medical Laboratory Technicians with interest in histology or neuropathology.

Applications in the first instance to the Senior Chief Technician. Tel. 01-856 5555. (801)

**IMPERIAL COLLEGE
UNIVERSITY OF LONDON
LECTURESHIP
IN PETROLEUM GEOLOGY**

Applications are invited for a Lectureship in the Department of Geology under the direction of Professor W. D. Gill, for the coming session. Requirements are a good degree and experience in the Petroleum Industry.

Salary depending on qualifications and experience in the scale £2,118 to £4,896 plus £213 London allowance. Superannuation under ESSU scheme.

Applications with curriculum vitae and names of referees to Professor W. D. Gill, Department of Geology, Imperial College of Science and Technology, London SW7 2BP. Closing date August 31, 1974.

(797)

**FELLOWSHIPS AND
STUDENTSHIPS**

**UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY**

Applications are invited for a Postdoctoral Fellowship for a project financed by the Nuffield Foundation for work with Dr M. J. Morgan on "The Regulation of Carbohydrate Metabolism in Animal Cell Culture." Experience in biochemical genetics and cell culture techniques would be an advantage.

The appointment would be for one year in the first instance, renewable for up to three years. Starting salary £2,118 p.a. with F.S.S.U. membership.

Applications, including curriculum vitae and the names of two referees should be sent to Dr M. J. Morgan, Department of Biochemistry, School of Biological Sciences, University of Leicester, Leicester LE1 7RH.

(723)

**THE QUEEN'S UNIVERSITY
OF BELFAST
RESEARCH STUDENTSHIP
IN ORGANIC
CRYSTALLOGRAPHY**

Applications are invited for a research studentship involving the application of X-ray crystallographic and computing techniques to the study of organic and organometallic compounds. The successful applicant should have an honours degree or G.R.I.C. and will be expected to proceed to a Ph.D. degree. Applications, with the name of one referee, should be sent as soon as possible to Dr J. F. Malone, Chemistry Department, Queen's University, Belfast, BT9 5AG.

(726)

**ROYAL HOLLOWAY COLLEGE
(University of London)
EGHAM HILL, EGHAM, SURREY
RESEARCH STUDENTSHIPS**

Applications are invited from suitably qualified graduates in Chemistry, Physics or Biochemistry for Research Studentships in Biophysical Chemistry and Surface Energetics. Successful applicants will be expected to register for a higher degree. Applications with a curriculum vitae and the names and addresses of two referees should be sent to Dr. P. J. Gardener, Department of Chemistry. (N) (729)

OPTICAL FIBRE COMMUNICATIONS

Communication by optical fibres is a rapidly expanding new technology which is being widely taken up by industry. The Laser research group at Southampton, comprising some 15 research workers, has been engaged in this field for some years with support from Science Research Council, industry and elsewhere. We have already announced world records for low transmission loss and high bandwidth in our fibres and wish to expand the present research team. Applications are therefore invited for a number of research fellowships, including a Pirelli Fellowship for work in collaboration with industry, at salaries linked to the scale for Lecturers in the range £2,118 to £3,462 plus threshold payments. Persons with an interest in any aspect of the subject are eligible. Applications giving details of education, experience and the names of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH. Please quote reference No. 231/R.

(734)

**European Molecular Biology Organization
(EMBO)**

**Short- and long-term fellowships
in molecular biology**

The European Molecular Biology Organisation intends to award to scientists working in laboratories within the European area both short-term (from a few days to several weeks) and longer-term fellowships for collaborative research or advanced training in molecular biology.

The Short-term Fellowships are to support visits to other laboratories for the purpose of carrying out experiments with special techniques or of other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

The Long-term Fellowships will usually be for a period of one year, but applications for renewal will be considered. They will be awarded upon individual application, at the "junior" level to promising young research workers who may then spend prolonged periods in other laboratories working under the guidance of leaders in the field of molecular biology. At the "senior" level, they may be awarded to enable established research workers to gain experience in new approaches and new problems. Upon application by European Institutions fellowships at the "senior" level may also be awarded to specialists who can assist in the initiation and development of research programmes in the sponsoring Institution. Such "sponsored" awards may be made to established workers at all stages of their career beyond the postdoctoral stage.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organisation, 6900 Heidelberg 1, Postfach 1022.40, Germany.

(521)

**UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF CHEMISTRY
S.R.C./C.A.S.E. STUDENTSHIP**

Applications are invited for a three-year studentship to work on the preparation and some reactions of novel inorganic fluorinating agents. The student will receive training in vacuum line techniques, chromatography and spectroscopy.

Supervisors—Dr. M. F. A. Dove (Nottingham) and Dr. G. Fuller (I.S.C. Chemicals Ltd.). Candidates must have the equivalent of a 1st or upper 2nd class Honours chemistry degree.

Applicants should send their curriculum vitae and the names of two referees to Dr. M. F. A. Dove, Department of Chemistry, University of Nottingham, University Park, Nottingham NG7 2RD.

(737)

**UNIVERSITY COLLEGE DUBLIN
DEPARTMENT OF ZOOLOGY**

Post Doctoral Research Fellowship in Paleolimnology under the sponsorship of the National Science Council.

Applications are invited for a Post-doctoral Research Fellowship to investigate the Post Glacial development of Loughs Ennell and Owel, Co. Westmeath. The position is tenable for one year with a possible extension to a second year.

Applicants must hold a doctorate or be about to submit. A knowledge of the taxonomy of the Chironomidae and Cladocera and techniques of coring and sediment chemistry are essential.

Salary to a suitably qualified candidate will be £2,100. The work will be based in Dublin and an allowance for field expenses will be paid.

Applications should be forwarded to the undersigned giving details of qualifications not later than Friday, August 30, 1974.

The Secretary,
Zoology Department,
University College,
Belfield,
Dublin 4.

(746)

**UNIVERSITY COLLEGE DUBLIN
RESEARCH FELLOWSHIP IN
POPULATION ECOLOGY**

A postdoctoral fellow is required for a project sponsored by the National Science Council on the ecology and control of insect pests in peatland. Applicants must have an honours degree in Zoology, postgraduate research experience in insect population ecology and should preferably have some experience of peatland ecosystems. Applications, with curriculum vitae, to Dr M. F. Ryan, Department of Zoology, University College, Belfield, Dublin 4, before August 23, 1974.

(747)

**CHELSEA COLLEGE
UNIVERSITY OF LONDON
CAMBRIDGE UNIVERSITY**

POST-DOCTORAL RESEARCH FELLOW

required from October 1, 1974 to study the excretion of nicotine and its metabolites in smokers of various age groups, in various pathological conditions and exposed to various environmental influences. The appointment will be for one year in the first instance with the possibility of renewal for a further two years. Salary £2,280 per annum. F.S.S.U. Superannuation Scheme. Apply with full curriculum vitae to Dr. J. W. Gorrod, Department of Pharmacy N, Chelsea College Annexe, 271 King Street, Hammersmith, London, W.6, as soon as possible.

(756)

**BREWING INDUSTRY RESEARCH
FOUNDATION
NUTFIELD, SURREY
MICROBIAL PHYSIOLOGIST**

A postdoctoral Microbial Physiologist is required in the Department of Microbiology and Fermentation to participate in wide ranging studies of the metabolism of yeast during fermentation.

The appointment will be made as a Research Fellow for a period of up to three years at a starting salary to be determined but on the scale £2,299 by £80 to £2,619 by £107 to £3,047. Threshold payments will be made additionally to basic salary.

Applications, including a curriculum vitae, should be sent to the Administrative Manager, Brewing Industry Research Foundation, Nutfield, Redhill, Surrey RH1 4HY.

(780)

**UNIVERSITY OF ABERDEEN
UNIT FOR RESEARCH ON ADDICTIVE
DRUGS**

A S.R.C. Studentship (Co-operative Award in Science and Engineering, C.A.S.E.) will become available on October 1, 1974. It is tenable for 3 years in co-operation with the Pharmaceutical Division of Reckitt and Colman Ltd., Hull, and is open to First and Upper Second Class Honours Graduates in Pharmacology, Biochemistry or Physiology. The research project is concerned with the action of newly-synthesised morphine-like compounds on neurotransmitter release and on behavioural patterns in normal and morphine-dependent animals.

Applications (3 copies) to be submitted to Professor H. Kosterlitz, Unit for Research on Addictive Drugs, University of Aberdeen, from whom further particulars may be obtained, Marischal College, Aberdeen AB9 1AS, not later than September 6, 1974.

(789)

MRC

Medical Research Council

Travelling Fellowships 1975-1976

The MRC invites applications from established workers of at least Registrar status, or with postdoctoral experience in the biomedical field in the case of non-medical graduates, for Travelling Fellowships available for a year from October 1975. The awards may be held at any centre abroad (although certain awards are tenable only in the USA).

The closing date for application is 21 October 1974.

Application forms and further details may be obtained from:

Medical Research Council, (Grants and Training Awards Section),
20 Park Crescent, London, W1N 4AL. Telephone: 01-636 5422 (Extensions 240 or 242).

(761)

IRELAND

FELLOWSHIP IN MARINE SCIENCE

The Pfizer Chemical Corporation, Ringaskiddy, Co. Cork, is sponsoring a Fellowship in Marine Science tenable at University College, Cork, under a scheme administered by the Fisheries Division of the Department of Agriculture and Fisheries.

Applications are invited from suitably qualified persons to undertake a study of some aspects of the ecology of Cork Harbour.

QUALIFICATIONS:-

ESSENTIAL—At least a Second Class Honours Grade 1 University degree in Zoology.

DESIRABLE—Experience in some aspect of Marine Biology. The initial starting stipend will normally be within the range of £1,600 to £1,800 per annum but a candidate with special qualifications may be appointed at a higher starting stipend.

Application forms and Conditions of Service attaching to the Fellowship may be obtained from:

The Secretary,
Department of Agriculture and Fisheries,
Fisheries Division,
Agriculture House,
Kildare Street,
Dublin 2.
IRELAND

Closing date for the receipt of completed application forms is 4.00 p.m. on Friday, September 6, 1974. (773)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

Research School of Physical Sciences
RESEARCH FELLOW/SENIOR
RESEARCH FELLOW

DEPARTMENT OF NUCLEAR PHYSICS

The Department, which has an academic staff of eighteen headed by Professor J. O. Newton, carries out work in nuclear structure physics. At present, main research activities are in the broad areas of heavy-ion interactions, direct interactions and nuclear spectroscopy.

The Department operates two major accelerators. The 14UD Pelletron Tandem Accelerator (14 MV terminal) was installed in 1973 and research work with it has recently commenced. It is intended that research with the 14UD will be mainly in the heavy-ion field.

The EN tandem (6MV terminal) is provided with a negative-ion cyclotron injector enabling acceleration of proton and deuteron beams with energies up to 38 and 26 MeV respectively. In addition the EN has a polarised ion source as well as the regular gas and lithium exchange source.

Closing date: **September 13, 1974.**

SALARIES: Salary on appointment will be in accordance with qualifications and experience within the ranges: Senior Research Fellow \$A13,163 to \$A15,348 p.a.; Research Fellow \$A9,002 to \$A12,269 p.a.; current exchange rates are approximately \$A1: 67p: \$US1.49.

Tenure: Senior Research Fellow and Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF before applying. (795)

SHEFFIELD POLYTECHNIC

Research Fellow in Biological Sciences

Applicants should be experienced in the biochemistry of microorganisms, with particular reference to biological recycling of industrial and town wastes and effluents.

The initial appointment will be for three years with the possibility of extension for a further two years.

Salary Scale: Senior Lecturer Grade: £3,525 to £3,915 (bar) to £4,212.

Application forms and further details obtainable from the Staffing Officer, Sheffield Polytechnic, Halfords House, Fitzalan Square, Sheffield, S1 2BB, to whom completed forms should be returned within fourteen days. (762)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointment:

SENIOR TEACHING FELLOW IN PHYSICAL AND INORGANIC CHEMISTRY

The Senior Teaching Fellow, who should have completed a Ph.D. degree, will devote about half his time to teaching and the other half to research. He will be responsible for supervising arrangements for some undergraduate practical courses and will initiate new course developments; he will be encouraged to undertake research with one of the existing research groups in the Department, which has good modern facilities. A document detailing research interests within the Department and describing undergraduate class arrangements is available on request (September 13, 1974).

Salary Scales: Senior Teaching Fellow \$A7,545 by \$A292(2) by \$A291(3) to \$A9,002, with superannuation provision.

Further particulars about this post and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, The University of Adelaide, North Terrace, Adelaide, South Australia, 5001. (796)

UNIVERSITY OF LEEDS

DEPARTMENT OF PHYSICAL CHEMISTRY

Applications are invited for two research posts to work with Professor P. Gray and Dr A. A. Clifford.

EXPERIMENTAL OFFICER: work on the measurement of the viscosity and thermal conductivity of the freons in the gas phase. Applicants should be graduates with good practical ability. Salary on the scale £1,752 to £2,376 (rates applicable from October 1974).

RESEARCH FELLOW: work on the measurement of the diffusion rates of hydrogen atoms in gases using the technique of resonance fluorescence. Applicants should hold a Ph.D. degree and have experience of research in a related field. Salary on the scale £2,118 to £2,412 (rates applicable from October 1974).

Appointment will be for one year in the first instance, with possible renewal for a further year. Applications to Dr A. A. Clifford, Department of Physical Chemistry, The University, Leeds LS2 9JT by August 23. (760)

SHEFFIELD POLYTECHNIC
DEPARTMENT OF CHEMISTRY
AND BIOLOGY

RESEARCH STUDENTSHIP IN "OPTICAL METHODS OF INDUSTRIAL ANALYSIS"

Applications are invited for this post, sponsored by Anacon (Instruments) Ltd., to commence in September 1974. Candidates should hold, or expect to obtain this year, a good honours degree or equivalent (such as GradRIC) in chemistry, chemical engineering or biochemistry, or an appropriate joint honours degree. Other qualifications such as FIMLT could also be considered. The successful candidate will be expected to register for a higher degree.

The project will involve study of applications of near-infrared and ultraviolet spectroscopy and refractometry to analytical problems, particularly in the context of on-line analysis, in a wide range of industrial processes (e.g. in the food, chemical and oil refining industries). The student will spend periods of work at the Anacon factory and at appropriate industrial plant, thereby gaining experience of taking a project from the laboratory through to the eventual application on the plant.

The post is for two years in the first instance, renewable for a further year. The value of the Studentship will be £800 per annum (plus all fees), but this may be supplemented by a limited amount of part-time teaching in the Department to afford approximately £1,100 per annum.

Application forms may be obtained from the Staffing Officer, Sheffield Polytechnic, Halfords House, Fitzalan Square, Sheffield, S1 2BB, to whom completed forms should be returned as soon as possible. (763)

UNIVERSITY OF LEICESTER

Department of Engineering

Applications are invited for a

Research Fellowship

for SRC-supported research into **high current-density electrochemical machining with molten salt electrolytes.**

Applicants should have at least two years postgraduate experience or a higher degree.

The post is for 2 years, with salary in the range £1,925 to £2,605 p.a. and superannuation benefits payable.

Further details and application forms may be obtained from the Head of the Engineering Department, The University, Leicester LE1 7RH (Ref. RF3).

Informal enquiries to Mr H. E. Freer or Dr A. C. Baxter.

(803)

LECTURES AND COURSES

"Combustion Fundamentals"

An introductory course of 14 post-experience lectures will be held at IMPERIAL COLLEGE from Monday October 14 to Friday 18, 1974.

Further information from Professor F. J. Weinberg, Department of Chemical Engineering and Chemical Technology, Imperial College, London SW7 2BY. (751)

FOR SALE AND WANTED

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:

Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes**, M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage**, D. P. Tihansky. **Effects of Red Mud on Marine Animals**, R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn**, M. Karpuzcu.

Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

MASS FRAGMENTOGRAPHY

For those who are interested in the metabolism of foreign compounds and related studies, especially methods using stable isotopes, and would like to know more about mass fragmentography, for those who know all about mass fragmentography and would like to do it, or do more of it, IRI has prepared a brief on the utility of this research tool, and its availability at IRI.

To receive this brief, without any obligation, write, telephone or telex:

Filtration for the biological scientist

This useful manual describes the basics of sample preparation using various Millipore filters with common LSC cocktails. The properties of Millipore filters in protein and nucleic acid binding studies are also described, along with filtration for microbiological sampling and separation, microchemical analysis, and radio tracer ultracleaning.

In all, there are 32 pages of information. Free. Ask for Manual AM 304.

YOUR FUTURE IN ELECTRON OPTICS...

If your laboratory is typical... its demands, when it comes to electron microscopy, are changing. One example of this change is a growing need for instruments that are easy to use, while producing top-quality micrographs.

As medical and industrial control applications become more routine, it will no longer be practical to restrict the use of an electron microscope only to a highly trained microscopist. It will have to be available **on demand** to anyone who needs it.

WILL YOU WANT EVEN NON-SPECIALIST OPERATORS TO PRODUCE TOP- QUALITY ELECTRON MICROGRAPHS?

If you foresee such a change in your future... why wait? There's a Philips microscope for you now. The Em 201C - with 2,5 Å resolution.

It may be hard for you to believe that such a compact instrument as this, with so few controls, out-performs many more complex instruments. But microscopists who have used it know it's true.

With the Philips EM 201C, the making of high-quality, high-resolution electron micrographs can become a **routine procedure**.

Not just in the future. Right now!

The details are in our full-colour, 24-page brochure. May we send you a copy?

PHILIPS

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Matters arising

Geomorphological dating of cave openings in South Africa—J. M. J. de Swardt	683
Reply—T. C. Partridge	683

100 years ago

On Saturday evening a lecture on the Transit of Venus was delivered by M. Faye, before a very large audience at the Cercle du Nord, a magnificent building, richly fitted up. The accomplished astronomer referred mostly to the arrangements at the French stations, deeply regretting that all civilised nations had not been united into a kind of federation for working in combination at a problem of such magnitude; he hopes that it will be so in 1882. He insisted upon the importance of photography, which has been used to such good purpose by the Americans, and he trusts that in future times photography will take the lead in such observations. He gave interesting details as to the Yokohama station, to which a Japanese prince educated in France will be attached as a photographer. The consequence will be that M. Jannsen and his associates will be admitted into the interior sea of Japan, where, up to the present moment, not a single foreign vessel has ever sailed.

From *Nature*, 10, 345, August 27, 1874.

Affinity Chromatography

with spacer groups

AH-Sepharose® 4B
CH-Sepharose® 4B

for coupling ligands containing a free carboxyl or a primary amino group to the Sepharose matrix via a six carbon atom "spacer" group. AH-Sepharose 4B, with a terminal amino group, and CH-Sepharose 4B, with a terminal carboxyl group substantially reduce the steric hindrance to binding which may occur when small ligands are coupled to the Sepharose matrix.

The ligands can be coupled directly to these "spacer" groups using a carbodiimide reaction, thereby reducing the number of synthesis steps required to make the adsorbent.

AH-Sepharose 4B, containing $-(CH_2)_6NH_2$ groups, and CH-Sepharose 4B containing $-(CH_2)_5COOH$ groups, are available in packs of 15 g corresponding to a gel volume of 60 ml.

Con A-Sepharose®

Provides new possibilities for the isolation of glycopeptides, glycoproteins and polysaccharides by affinity chromatography. Concanavalin A has been coupled to Sepharose 4B by the CNBr method and reacts specifically with terminal D-mannose-like residues.

Con A-Sepharose is available in packs containing 100 ml sedimented gel, 800 mg bound concanavalin A.

and without

CNBr-activated
Sepharose® 4B

is a ready activated matrix to which proteins and other molecules containing primary amino groups may be coupled directly. The procedure is quick, easy and safe, and preserves the binding activity of sensitive ligands.

CNBr-activated Sepharose 4B is the material of choice for the immobilization of macromolecules in the preparation of biospecific adsorbents for affinity chromatography. Its use in the study of proteins, nucleic acids, polysaccharides etc. is already well documented. Sepharose provides a matrix which is stable, has a high capacity even for very large molecules, and displays low non-specific adsorption.

Freeze-dried CNBr-activated Sepharose 4B is available in packs of 15 g corresponding to a gel volume of 50 ml.

Mr Benn's mixture of good and bad

BRITISH industry is in a woeful mess; there is little disputing that and small comfort in the knowledge that nowhere in the world is industry doing outstandingly well at present. Nor is the malaise a thing of the recent past. For many years the danger signals have been flying, as Britain's growth has become sluggish and as industrial investment has fallen off.

A long period of decline will require a long period of recovery; certainly no tactical change of course that a single budget could effect will help much and this is the importance of Mr Benn's proposals in *The Regeneration of British Industry*, just published as a White Paper (Cmnd 5710). Nothing less than an immense strategic rethink is necessary and the time when industrialists could simply ask to be left alone is well past. The crudity, so far, of the advertisements of Aims of Industry—a group of employers dedicated to free enterprise—suggests that there are many who still do not appreciate that what is desperately needed now is discussion and not rhetoric. Lack of business confidence, which is what the decline in investment is all about, cannot be treated by urging support of the status quo.

That, at least, is certainly far from Mr Benn's intention. Government and industry, the document argues, have dealt too remotely with each other; and industry has seen the government's function as one of regulation. Now it is time for partnership, and this is being proposed in two fairly distinct ways.

First, there will be Planning Agreements with major firms to ensure harmony with national needs and objectives and to provide a better basis for governmental aid. The agreement will be a rolling three-year look at company plans, and if necessary will provide discretionary financial assistance. The agreement will be drawn up by management 'in close consultation with trade union representatives' who will be provided with all necessary information for effective consultation. The government sees this as a major advance in industrial democracy. In return for companies opening up their plans to Whitehall, they will have the benefit of "the government's views on the likely development of the economy".

The second proposal is for a National Enterprise Board (NEB) and it is through this that the government will channel large scale investment in exchange for equity. It will also take over the government's holdings in companies such as Rolls-Royce (1971) Ltd, assist industrial reorganisation, start new ventures and extend public ownership into profitable manufacturing industry by buying up to 100% of the equity. Criteria for acquiring a profitable company will include the danger of its passing into "unacceptable" foreign control, and the

stimulation of competition. The NEB may also take over an ailing company for reasons of regional employment or "industrial policy". The board will ensure that enterprises under its control fully involve employees in decision making. Mr Benn is restrained by the requirement that all major deals require government approval and the Cabinet, much less to the left on average than Mr Benn, will presumably moderate his undoubted vigour.

The timing of the document makes it quite obviously an election manifesto since nobody seriously believes there will not be an election before the White Paper can be put to the vote. And it is this reminder of the fluctuations of politics which casts some doubts on the two schemes. If a Labour government guarantees a three-year planning agreement, will a subsequent Conservative government dismantle it? Surely this would provide for even less investment confidence and so there is a need for the two major parties to hammer out something which they can each live with. The document, as it now exists is more moderate than was originally planned. Even so, the thought of trade unions looking at the books and helping to make decisions will still terrify most Conservative Members of Parliament and may make the whole programme unacceptable if Labour is still a minority government when legislation is being considered.

This would be most unfortunate. If there is one thing that desperately needs attention in Britain, it is the them-and-us divide which permeates industry and most other things too. Industrial democracy, common in many other countries, has to come soon and Mr Benn is right to push for it.

The other compulsory match for industrial management is with government, and this is a dubious affair indeed. The problem is that government has no evidence to show that it has any unusual skills or knowledge to offer. No doubt there will be some bright people recruited into the NEB and Planning Agreement section of the Department of Industry but on the whole staffing will be accomplished by shuffling the pack of civil servants. Is there any evidence that they will be a desirable commodity for industry? And the political masters; well they are much the same as those who were going to harness the technological revolution in 1964, and it is the failure to do that which has contributed much to Britain's present depressed state. No doubt the agreements will allow civil servants to pass on the minister's thinking in their offices instead of their clubs, but vigorous industry is more likely to be able to shape the minister's thinking by its successes than to be shaped itself because of its failures.

If the planning agreement concept suggests the gaining of doubtful benefits from Whitehall, the NEB investment and takeover scheme is worse. The reward for running a profitable company is to find not only the unions but also the government wanting a large piece of the action. No self-respecting manager will stay with a firm in which success is recompensed by loss of responsibility. If there is so much talent in Whitehall, it should surely be used to revive less successful industry.

The changing relationship between science and technology

J. Langrish of the Manchester Business School examines the way in which the relationship between science and technology has changed in the past and is about to change again.

IN recent years, the belief that technological change is somehow based on scientific advance has been increasingly challenged. Price¹, for example, has claimed: "The naive picture of technology as applied science simply will not fit the facts. Inventions do not hang like fruits on a scientific tree. In those parts of the history of technology where one feels some confidence, it is quite apparent that most technological advances derive immediately from those that precede them".

Technological change has been increasingly seen as the adaption of existing technological concepts in response to demand. Schmookler², for example, has attempted to show that the variation in inventive activity between different American industries is explicable in terms of the variation in demand, concluding that economic growth determines the rate of inventive activity rather than the reverse. None the less, governments have continued to invest in scientific research at a level much greater than other activities which can also claim cultural and prestige benefits. Science receives much more money than the Arts because it is believed to be useful. When science is not used, it is claimed that there is a communication barrier; the alternative possibility that it is intrinsically of no use is not examined.

One of the major problems in looking at the usefulness of science is a matter of definitions. What is Science? What is Technology? To avoid this problem, we must ask questions such as, what is the effect of university research and research in government laboratories on industrial change, or on improvements in health and agriculture.

A study³ of 84 British technological innovations showed that "demand pull" occurred more frequently than "discovery push" and that out of 158 key technical ideas made use of in innovations, 56 originated within the innovating firms and of the remaining 102, 7 came from a British university and 17 from a British government labora-

tory (including Research Associations).

The apparent conclusion that ideas from British universities had little effect on British innovation was challenged in a variety of ways. One of these was the claim that although industrial innovation may be based on industrial research, the day to day progress of industrial research depended on university research in ways that would not be revealed in looking at 'key ideas'. It was pointed out, for example, that industrial chemists spend time reading the results of university chemical research.

To examine the relative contribution of university research in the literature cited by industrial researchers, seven review articles written by British industrial chemists were examined⁴. The reviews contained 567 references to other publications (including patents) and the institutional origins of 396 of them were identified. Only 23 out of the 396 references were to the work of British universities and of these, 7 stated that some industrial finance had been involved in the research. British government institutions seemed to be more interesting to the industrial reviewers in that 45 of the references were involved. Table 1 compares the relative importance of the institutional origins of the 102 "key ideas" with the origins of the 396 references and also the origins of 452 abstracts to be discussed later.

These results suggest that British university research has little impact on British industry. Why then does the British government continue to finance university research? One possible reason is that university research only occasionally produces results of economic benefit but when it does the benefits are so large that they outweigh the total costs of all university research for several decades. An example of this kind in the present century would be the research that led to atomic power. A more fruitful source of such examples is the last half of the last century.

There is little doubt that German university research in organic chemistry, for example, provided the foundations for the German synthetic dyes industry and subsequent advances in pharmaceuticals, synthetic rubber and plastics. Similarly the electrical industries can be seen as being based on nineteenth century academic research.

At the time of the First World War Britain realised that Germany had advanced industrially by using the results of scientific research, and in 1917 the Department of Scientific and Industrial Research was established. Since then, the British government has ploughed increasing amounts of money into scientific research in the belief that what was good for Germany in the last century should be good for Britain now.

But times have changed. Reliance on the German example does not seem to have been justified. One possible explanation is that the relationship between science (university research) and technology (industrial practice) has changed since the last century. To test this hypothesis, abstracts produced by the *Journal of the Society of Chemical Industry* were examined. For some eighty years, this Journal produced abstracts of the world's literature that might be of relevance to industrial chemists. Even in the last century, large teams of abstractors were used, reducing the possible bias of an individual. The abstracts were classified according to industrial subject matter, and those classes which might be considered to rest on organic chemistry were chosen for examination.

The original publications selected by the abstractors as being worth the attention of industrial chemists were consulted and wherever possible, institutional origins identified. Initially, the years 1884, 1917, 1935 and 1952 were examined but the difference in institutional origins between 1884 and 1917 was so great that the year 1899 was added to the investigation.

Table 2 shows the institutional sources of abstracts in randomly selected editions of the Journal for the given years. (A small proportion of abstracts in all years defied attempts to identify origins. The figures given are for identified sources.)

Teaching establishments are included under the category of university as are research laboratories and institutions attached to universities. The 'government' category includes Research Associations, government-financed industrial laboratories and military establishments.

Several of the abstracts were to patents some of which caused difficulties in the assignment of origins. Early patents usually give the name and pro-

European industry-university collaboration	—	—	
Total industry-university collaboration	—	6.5	5.0

fession of the inventor. In most cases the profession enabled a classification to be made, such as 'professor'—university; 'merchant'—industry. But descriptions such as 'gentleman' or 'subject of the Czar' had to remain unclassified unless the inventor could be identified from other sources. Papers by joint authors from different types of institutions were scored $\frac{1}{2}$ each.

It can be seen from Table 2 that there has been a marked change in the relative importance of the institutional origins from European university (mainly German) to European industry and then to American industry as being the major contributors selected by the abstractors.

Although some of the change may be due to changes in abstractors or journal policy, the large decline in the relative importance of university publications from 61% in 1884 to 6% in 1952 and the steady growth in the importance of American industry from 0 in 1884 to 54% in 1953 can be assumed to be the result of a change in the relationship between university research in organic chemistry and those industries which use organic chemicals.

The data for 1952 are included in Table 1 for comparison with the studies previously mentioned. The data are based on an examination of 544 abstracts of which 59 could not be found, 6 had insufficient information and 27 were unclassifiable patents, leaving 452 identified origins. The three different studies give different percentage inputs but it should be noted that in all three studies:

- Foreign industry was the major source of inputs

- UK industry was the second most frequent source in two studies and the fourth most important in the other

- UK university was either the least important source or next to the least.

The dramatic change which has taken place since the days when German university research was providing results of direct relevance to the German dyestuffs industry may be explained by two alternative hypotheses:

(1) Industry has taken over its own research. The massive growth in industrial research since German industry employed teams of chemists to search for new dyes may explain the decline in apparent relevance of university research. However, university research has

also grown enormously since the last century. (An interesting account³ of the growth of British industrial research has been given by Sanderson.)

(2) A new branch of science is only useful in its early days. The early days of astronomy as a science were linked with economically important attempts at improving navigation but astronomy has hardly been useful since then. (Even earlier, astronomy was used to maintain the power of priestly castes.) The early days of atomic power involved theoretical physicists; since then the theoretical physicists and the designers of nuclear power stations have moved further apart.

The early days of organic chemistry involved the production of new chemical substances and new ways of making them. Since then the university chemist has been more concerned with understanding the results of early research; the industrial chemist has been concerned with using the early

knowledge and is not too interested in later theoretical developments.

One of the seven review articles referred to earlier was about 'polyolefins' and only 14 out of 102 identified references were to university research in spite of the fact that the present industrial importance of such materials as polypropylene started with the non-industrial research of Ziegler and Natta who may be considered to have founded if not a new branch of science, at least a new stem entitled stereospecific polymerisation.

It was decided, therefore, to test the above hypothesis by looking at earlier reviews of 'polyolefins' by industrial chemists. Table 3 shows that the relative importance of university contributions dropped from 50% in 1957 to 14% in 1967, although the absolute number of university contributions remained constant.

Another point of interest is that British industry began publishing items of interest to the reviewer before British universities. This was not because British universities ignored stereo-

specific polymerisation. It was because universities concentrated on the scientific problem of describing and explaining the mechanisms involved and the structure of the polymers produced whilst industry concentrated on obtaining manufacturing processes and improving properties such as light resistance. From a common origin, the discovery of stereospecific polymerisation, academics and industrialists have moved in different directions.

The relationship between university research and industry may well be a function of the degree of development of the area concerned. Once a new area has been established, the aim of science is to understand; the aim of technology is to make it work, and industry has been very successful at making things work without too much reliance on understanding.

Industry makes use of the trained manpower supplied by universities. It also uses new techniques such as chromatography, developed in universities. But the new products and processes of industry seem to depend on a combination of existing technological concepts, economic pressures and empirical research with scientific understanding not being very relevant.

This does not mean that university research is a waste of money; the situa-

tion may be changing. Concern about such matters as resource depletion, ecology, pollution, fire risk, health hazards and quality of working life coupled with the increasing scale of industrial operations may mean that industry will have to pay more attention to understanding what it is doing.

In the study of 84 innovations mentioned earlier, the only example of theoretical work in a British university assisting British industry was in the area of steel frames for building construction. A concern for human safety together with a shortage of steel led to the use of Baker's theory of plastic flow to design buildings which are safe but use less steel.

It could be that in the future, many sections of industry are going to require an increasing reliance upon theoretical research aimed at understanding, as the empirical approach, which has been so successful, joins the quest for economic growth as a thing of the past.

It would seem, therefore, that there are both macro and micro effects leading to changes in the relationship between science and technology.

At the micro level, the relevance of a particular part of science has depended on its degree of development. At the macro level, the relationship

seems to move in cycles, with the first half of the nineteenth century involving little reliance upon scientific theory (although the scientific technique of methodical observation was made use of) the second half of the nineteenth century being characterised by a series of inputs from research concerned with exploring scientific problems, the first half of the present century being a triumph of industrial methodical empiricism and the future requiring an increasing dependence on understanding.

I thank the Department of Education and Science and the Programmes Analysis Unit for funding parts of this research and Trevor Parkinson for his considerable ingenuity in tracking down the institutional origins of some of the more obscure references.

international news

A WORKING party under the chairmanship of Lord Ashby, Master of Clare College, Cambridge is being set up by the Advisory Board for the Research Councils to "make an authoritative assessment of the potential benefits and potential hazards of techniques which allow the experimental manipulation of the genetic composition of microorganisms".

At the same time the Medical Research Council (MRC) has made public the fact that they have asked their staff members not to embark on experiments in bacterial manipulation vetoed in the recent National Academy of Sciences (NAS) statement.

The letter circulated to directors of those MRC units which have the capacity to carry out work in this field asked that no experiments of type I and II in the NAS statement be undertaken in the near future until the working party has reported. This covers work on recombinant drug resistance plasmids that do not occur

Improper plasmids?

by Eleanor Lawrence

naturally, and the linking of animal virus DNA to plasmid DNA and its subsequent introduction and replication in a bacterial cell.

Directors were also asked not to initiate research on linking animal DNA to plasmid or bacterial DNA, which, according to the NAS statement, "should not be undertaken lightly." Experiments of this kind have already been carried out in the United States.

According to a spokesman for the MRC, the council supports no programmes actually involving research of the kind mentioned by the NAS, although the separate techniques are being studied in various laboratories.

He estimated that about 50 laboratories in Britain have the capacity to carry out genetic manipulation of the sort vetoed by NAS, but that until now there had been a self-imposed holding back from this type of experiment, which has been technically possible for some time.

The establishment of a working party to clarify the issue is generally welcomed, as the part of the NAS statement referring to drug resistance plasmids is felt by some to be ambiguous; it could, for example, be interpreted as banning experiments necessary for important public health work. Other workers also feel that the ban on introducing animal genes into bacterial cells could hold up work on new ways of producing important substances such as insulin.

The working party will consist of "high-level scientists" and the Advisory Board for the Research Councils hopes to be able to announce the membership within the next two weeks. □

Focus on astronomy

by John Gribbin and Ian Ridpath

A RECENT flurry of activity related to observational astronomy has emphasised that the obituaries for British optical astronomy may have been written too soon. Certainly the prospects for optical astronomy in Britain are dim; but the stirrings of the supposed corpse are having repercussions around the world, emphasising the international nature of modern astronomy.

Anglo-Australian Telescope: The AAT is the furthest of these projects from Britain geographically, but perhaps the most important in scientific terms. In spite of the usual difficulties of marking out territory on international projects (which will be familiar to readers of Fred and Geoffrey Hoyle's book *The Inferno* (Heinemann, 1973)) the project is still more or less on schedule. The official timetable, which sees commissioning of the telescope in October with completion of alignment and testing of optics and instrumentation in December of this year, looks a trifle optimistic. But it does seem that the facility will be ready for use early in 1975.

Infrared telescope for Hawaii: The SRC recently announced the decision to go ahead with construction of a 3.8 m (152-inch) infrared flux collector on Mauna Kea in Hawaii. This ends long speculation about the future of British infrared astronomy, and will result in the world's biggest 'purpose built' infrared telescope being located at a site which is recognised by astronomers as one of the best in the world. The SRC will lease the site for the instrument from the University of Hawaii, which already operates an observatory on Mauna Kea, at a height of 4,200 m.

This project has suffered more than most from political intervention, with sites such as Tenerife being ruled out because of poor relations between the British and Spanish governments. But for once the astronomers may have come out well from the politicking, since it seems likely that the Hawaii site would have been felt too remote for administrative convenience if an alternative closer to home had remained viable. The site is also convenient from a practical point of view, because it is far enough south to provide a good view of the galactic centre, a region of great interest to infrared astronomers. The construction costs for this telescope are estimated as £1.25 million at January 1974 prices, and construction is expected to take three years.

Mr Gordon Carpenter, the project manager, said last week that tenders

are now out and are expected back in early October. The site allocated is on the same mountain ridge as the University of Hawaii 88-inch optical telescope, and so most of the access roads and so on are already there. It should be possible to pour the first concrete in 1975, he said.

All this must make hot favourite as the location for the Northern Hemisphere Observatory, about which a decision is thought to be imminent.

South Africa: Amidst all this lightening of the astronomical gloom which has been so prevalent in recent years, a few storm clouds remain as a reminder that astronomers have not entirely abandoned their centuries-old tradition of internecine squabbling.

Since the opening of the new South

Hartebeesthoek tracking station

African Astronomical Observatory, with its observing station at Sutherland in the Karoo and its headquarters at the Cape Observatory, the former Republic Observatory in Johannesburg has been effectively abandoned. The observatory's buildings in Gill Street stand silent and empty, with the 26½-inch refractor, responsible for the observatory's world-renowned work on double stars and classic colour photography of Mars, now under mothballs in its dome.

Only one astronomer remains at the observatory, examining plates taken for minor planets with the 10-inch Franklin Adams telescope at Hartebeestpoort, 50 miles outside Johannesburg.

The decision to cannibalise the Republic Observatory and concentrate efforts at the Sutherland was received with mixed feelings by astronomers a few years ago, and Dr William Finsen, formerly Director of what was once South Africa's national observatory, was among the critics who spoke out against what he saw as a wrong decision by the SRC and the South African

Council for Scientific and Industrial Research (see *Nature*, 229, 355; 1974). Today, Finsen is in retirement and virtually an outcast from the South African astronomical establishment. For good or bad, however, the reorganisation of observational astronomy in South Africa is now essentially complete, and under the forceful direction of the former Astronomer Royal Sir Richard Woolley, it is hardly likely to become a backwater.

South African radio astronomers, meanwhile, like their infrared colleagues in Britain, seem to have benefited from a partially politically oriented decision. The 26-m (85-foot) radio dish of the former NASA deep-space tracking station at Hartebeesthoek, near Pretoria, ceased operation at the end of June this year, officially as part of "an overall consolidation activity" to prune the NASA tracking network. Privately, however, astronomers say that pressure from black politicians in the United States is believed to have influenced the decision. The associated tracking station for Earth-orbiting satellites is to close next year.

The deep-space station, opened in 1960, has been used to track all NASA's unmanned probes to the Moon and planets; it has now been taken over by South Africa's Council for Scientific and Industrial Research, and is being modified to work as a radio astronomy observatory. Initially the aerial will work at a wavelength of 13 cm, and eventually wavelengths as short as 4 cm will be available. The South African radio astronomers hope to have the telescope operational by the end of the year, and perhaps as soon as September. Surprisingly, however, no firm programme has yet been decided; but the interest of the observatory's director, George Nicholson, in quasars and extragalactic work is certain to make itself felt.

Leaving aside this somewhat fortuitous windfall to the radio astronomers, the revival of British and associated optical astronomy can in retrospect be traced back over several years. Certainly five years ago there was cause for concern; but with hindsight it is becoming clear that the problems have been recognised and to a large extent tackled. Projects such as the Schmidt at Siding Spring, the AAT and the new infrared telescope are now becoming physical realities, and allowing for the inevitable delay in the filtering of the resulting benefits through the system, the patient may not only be able to take up his bed and walk but may even be running around in the first team in another ten years or so.

Megalithic alignments

SIR,—In your editorial "Science beyond the fringe" (April 12) you speak of archaeology as "plagued by a series of ideas which have achieved a following particularly among the young". The extreme example you give of this is "people busily poring over Ordnance Survey maps of Britain plotting mythical alignments between ancient monuments and erecting fanciful hypotheses about prehistoric technological civilisations." To this, as you say, Professor Glyn Daniel has objected in his *Antiquity* editorials.

Please allow me, as an author on the subject ridiculed in your editorial, the privilege of a brief comment.

You declare that alignments between ancient monuments are "mythical" and hypotheses about advanced prehistoric civilisations "fanciful", although as editor of a scientific journal you are of course aware that your statement of opinion does not necessarily make them so. It is ironical that the first man to detect significant alignments between megalithic sites was your predecessor, Sir Norman Lockyer, editor of *Nature* for the first 50 years of its existence. In fact, despite the studied neglect with which Lockyer has been treated by archaeologists throughout this century, his main conclusions, that megalithic sites were inter-related and orientated by astronomical considerations, are now generally accepted, even by the editor of *Antiquity*, as the result of recent work by Professor Thom and other astro-archaeologists. The quality of criticism brought against Lockyer and his school is typified by the comment with which O. G. S. Crawford, a former editor of *Antiquity*, dismissed the evidence of A. Watkins relating to the deliberate alignment of ancient sites: that it was "based on a misconception of primitive society." This comment perfectly illustrates the determination of modern archaeologists to prefer the basic historical paradigms they have set up above any evidence that might contradict them.

Personal experience shows that archaeologists, Professor Daniel included, simply refuse to review facts and evidence tending against current orthodoxy. In a book published by Garnstone Press early this year, *The Old Stones of Land's End*, I demonstrated, in a way that must convince any reasonable person who cares to

check the facts, the existence of planned megalithic alignments in West Cornwall. The book attracted a good number of local reviews but not one public comment by any archaeologist. It is therefore rather galling to read your account of archaeologists being "plagued" by theories of the inter-relationship of megalithic sites. Would not their best remedy be to attempt a serious refutation of the evidence offered them?

Your faithfully,

JOHN MICHELL

Call for biohazard legislation

SIR—Although Brian Ford (*Nature* August 2) refers to various Acts of Parliament, he makes no mention of the Safety and Health at Work etc. Act which received the Royal Assent on July 31. Clauses 2(2)(b) and 3(1) of the Act place a general duty on employers to protect both their workers and other persons from risks to health in connection with the use, handling, storage and transport of articles and substances; and under Clauses 15 and 16, the Secretary of State may make Regulations, or the Health and Safety Commission may prepare and issue Codes of Practice (or approve Codes of Practice prepared by others) for any of the general purposes of the Act. I would therefore suggest that no further legislation is necessary and that the way is clear for agreed Codes of Practice to be promulgated to deal with the different groups of organisms, as Brian Ford suggests.

Yours faithfully,

J. A. TANNAHILL

Employment Medical Advisory Service,
Department of Employment,
London, UK

Population policy study

SIR,—I should like to bring to the attention of readers of *Nature* a survey of the field of reproductive biology and contraceptive development sponsored by the Ford Foundation. The Foundation has asked for an inventory of where we stand in terms of (1) knowledge concerning the reproductive process and fertility control and (2) the human and financial resources that are being brought to bear on the matter of bringing population growth

within tolerable limits. For the conduct of this study, a headquarters has been established in Boston with a worldwide network of collaborators and consultants and an international advisory committee drawn from public and private donor agencies, universities and the pharmaceutical industry.

The force that motivated this major study is the accumulating evidence that an inadequate global effort is being waged in this field. The illusion is that the pressure of more immediate bio-social problems supersedes the need to control human fertility. The facts are otherwise.

The survey was initiated in July 1973 and is expected to be completed in 1975. The findings will be published in full on completion of the survey and as interim reports on special topics.

The comments, views and opinions by readers of *Nature* concerning any or all aspects of this survey will be welcome and helpful in drafting recommendations and guidelines for building on present progress in the understanding of reproductive phenomena and stabilisation of the global populace on a level commensurate with a high quality of life and human dignity.

Yours faithfully,

ROY O. GREEP

Laboratory of Human Reproduction
and Reproductive Biology,

Astronomical independence

SIR,—I write to correct John Gribbir who, in discussing (*Nature* 250, 538 1974) the thousandth issue of *The Observatory*, wrongly describes it as the house journal of the Royal Astronomical Society. His mistake is understandable since *The Observatory* does by long tradition, report the proceedings of the Society's meetings and is circulated to all Fellows of the Society. It is, however, published by 'The Editors of "The Observatory"', as is clearly stated in each issue, and has no official connection with the Society. The Editors, indeed, fiercely maintain their independence.

Our house journal is *The Quarterly Journal of the Royal Astronomical Society*.

Yours faithfully,

JOHN SHAKESHAFT

Royal Astronomical Society,
London

news and views

Giant extragalactic radio sources

MANY of the powerful extragalactic radio sources have dimensions much larger than those of the active galaxies which have supplied the vast energies required. In the case of the brightest radio source for example, Cygnus A, most of the radio emission originates, not in the galaxy associated with the source, but in two symmetrically disposed regions, one on either side of it. The peaks of maximum radio brightness are located about 100 kiloparsecs (equivalent to 3×10^5 light years) from the galaxy, the radius of which is only about 10 kpc. Such objects are the most common type of powerful extragalactic radio source found in source surveys although, as compared with the space density of ordinary galaxies, they are very rare indeed.

Detailed radio studies of the structures of these objects have been made possible by the development of the large aperture synthesis telescopes, first at Cambridge and more recently in The Netherlands (the Westerbork Synthesis Radio Telescope, WSRT). Several hundred of the brighter ones have been mapped with an angular resolution of $23''$ and a smaller number with higher angular resolution, that of the Cambridge 5 km telescope being $2''$ at a wavelength of 6 cm. There is no detailed source model which commands universal acceptance since the radio maps have revealed difficulties with each of the models proposed. All models, however, postulate the presence of magnetic fields within the components to produce the synchrotron radio emission, and of cold intergalactic gas in the vicinity of the sources to account for the complex radio structures observed.

Until now the maximum overall dimensions of these radio sources have been thought to be about 1 Mpc, which is the characteristic scale of clusters of galaxies rather than of galaxies themselves. Many radio sources are known to lie close to the centre of clusters of galaxies and for a while it has looked as if there might be a relationship between these two scales particularly since there is good evidence, from X-ray observations, for the presence of hot diffuse gas in clusters. If this relationship were true, however, it would be disappointing from the cosmological point of view because one might have hoped to use the radio components of the largest double radio sources as probes of the diffuse intercluster gas where most of the mass of the Universe may well reside.

On page 625 of this issue of *Nature*, Willis, Strom and Wilson report very interesting observations made with the WSRT and show that radio sources with physical sizes greater than 1 Mpc do indeed exist: the radio sources 3C236 and DA240 are extended, with total physical sizes, projected on to the celestial sphere, of 5.7 and 2.0 Mpc respectively. Credit for drawing attention to these objects goes to workers at the National Radio Astronomy Observatory (Bridle, Davis, Fomalont and Lequeux, *Astr. J.*, **77**, 405; 1972) who, in a definitive survey of bright radio sources at 1,420 MHz, found them to lie in "confused" regions and were unable to decide whether the radio sources in close proximity on the sky were physically related or simply chance associations of unrelated objects. In the first two cases studied by Willis, Strom and Wilson, the maps

show unambiguously that these sources are in fact associated and form components of extended double radio sources on a scale much larger than has been known before.

These observations are important for cosmologists, cosmic ray physicists and for the student of the physics of extragalactic radio sources. For the cosmologist there is the prospect of probing the intercluster gas and setting direct limits to the pressure of such gas. For the cosmic ray physicist, there is now the direct evidence that clouds of cosmic ray electrons can be ejected beyond the confines of a cluster of galaxies in times much shorter than cosmological time scales.

For the radio source theorist, these objects stimulate new speculations. First, nobody has ever been clear about the ultimate fate of a powerful double radio source. The present observations suggest that in some cases the components expand, preserving the relativistic particles within their lobes, until very late stages in their evolution. Second, the observation of polarised radio emission from the components of DA240 indicates surprisingly low densities of cold matter inside the components. Third, and perhaps most interesting, there is the observation of a compact double radio source associated with the parent galaxy in the case of 3C236. It is usually assumed that these components are moving away from the nucleus of the galaxy in opposite directions. The axis of this compact double is almost perfectly aligned with the axis of the giant double source components. On any theory of the extensive components, the latter must be able to 'remember' for hundreds of millions of years the direction in which to supply energy. Similar phenomena have been known before—in the radio galaxies Centaurus A and 3C66 for example—but 3C236 is probably the clearest case yet. Observations of Cygnus A forced Hargrave and Ryle to conclude that a continuous supply of energy over tens of millions of years is essential if one is to account for the structure of the components, but present observations are evidence that a continuous supply of energy may occur for even longer, in the oldest sources. These new observations, and others in progress at Westerbork, will therefore be seized upon by cosmologists and cosmic ray physicists, and will provide yet another link in the chain of our understanding of the physical evolution of extragalactic radio sources.

M. S. LONGAIR

Organisation of sequences of rRNA

THAT the sequences of both 28S rRNA of the large ribosome subunit and 18S rRNA of the small subunit are contained in a single precursor has been known for some time; for this constitutes one of the rare cases where a synthetic system was defined first with eukaryotic and only later with prokaryotic cells. The size of the precursor varies; in HeLa cells it sediments at 45S, so that only 56% is conserved in the form of mature rRNA sequences, but in *Xenopus* it is smaller (2.7×10^6 daltons instead of the mammalian 4.1×10^6 daltons) and almost 80% is conserved. The processing

pathway is best defined in HeLa cells. By utilising an electrophoretic analysis of nucleolar RNAs, Weinberg and Penman (*J. molec. Biol.*, **47**, 169–178; 1970) found that the 45S primary transcript is cleaved to a 41S molecule, which in turn is split into a 32S and a 20S RNA; the 32S molecule then matures into 28S rRNA and the 20S molecule matures into 18S rRNA. By analysing the oligonucleotides into which these species are broken by ribonuclease, Maden, Salim and Summers (*Nature new Biol.*, **237**, 5–9; 1972) confirmed that the 41S precursor contains both 28S and 18S sequences and that the 32S and 20S precursors respectively contain sequences of only the 28S and 18S rRNA molecules. Because oligonucleotides were identified by their content of labelled methyl groups, these experiments showed also that all the methyl groups added to 45S RNA are located in regions of the molecule destined to become mature rRNAs.

The identification by Seeber and Busch (*J. biol. Chem.*, **246**, 7151–7158; 1971) of common 5' terminal sequences in 45S, 32S and 28S RNAs of Novikoff hepatoma cells showed that the 28S rRNA sequences is located at this end of the precursors which contain it. The elegant analysis of RNA secondary structures reported by Wellauer and Dawid (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2827–2831; 1973) achieved a more precise location of ribosomal RNA sequences in the precursors. The 45S precursor contains a 5' terminal structure corresponding to 28S rRNA, with the 18S rRNA located within the remaining sequences; the 41S RNA structure is similar but lacks all the material on the 3' side of the 18S sequence. The cleavage that generates 32S and 20S precursors must take place within the central non-rRNA region, since 32S RNA has 5' terminal 28S sequence and 3' terminal non-rRNA sequence; and 20S RNA has a 5' non-

rRNA sequence with 18S rRNA located 3' terminally.

Each ribosome contains one 5S rRNA molecule in addition to the major RNAs and this seems to be coded by genes dispersed in the genome whose transcription is independent of that of the main precursor. The presence of another small RNA was first revealed by Pene, Knight and Darnell (*J. molec. Biol.*, **33**, 609–623; 1968), when they found that denaturing treatments release a small fragment from 28S rRNA. Originally characterised as 7S RNA, this molecule must be covalently linked to 28S rRNA, and more accurate characterisation has led to its recent description as 5.8S RNA. Synthesis of 5.8S RNA seems to be linked to that of the large rRNAs—kinetic experiments suggest its derivation by cleavage from the 32S precursor in HeLa cells. The sequence of the HeLa 5.8S RNA has now been examined by Maden and Robertson (*J. molec. Biol.*, **87**, 227–236; 1974), who have compared the oligonucleotides released by T1 ribonuclease with those cleaved from the rRNA precursors. When 28S rRNA is prepared by cold phenol extraction, it retains the 5.8S fragment; but heat treatment separates 28S rRNA from its small attached molecule. Correspondingly, upon T1 ribonuclease analysis, these two preparations of 28S RNA differ in the oligonucleotides characteristic of 5.8S RNA. One equivalent of the 5.8S RNA sequences is present for every equivalent of 28S RNA.

Fingerprints of the 32S RNA precursor show that it possesses the oligonucleotides constituting 5.8S RNA, again in molar yields which suggest the presence of one 5.8S RNA sequence in each precursor molecule. Some evidence for the presence of these fragments in 45S RNA is also presented. Although not yet precisely placed within the precursors, the 155 nucleotide long 5.8S RNA presumably lies between

Multifunctional gene in a eukaryote

ON page 630 of this issue of *Nature* Bollon presents a genetical analysis of a "multifunctional" eukaryotic gene, threonine deaminase, concerned with both structure and regulation.

Working with the yeast, *Saccharomyces cerevisiae*, Bollon found that the *ilv1* gene not only encodes for a gene product that is catalytically active (that is, L-threonine deaminase; EC4.2.1.16) but also that the gene product is involved in multivalent repression of the other isoleucine-valine enzymes. It has thus been possible, by careful genetical analysis, to discriminate between the nucleotide sequences that encode for that structural (=catalytic) and regulatory (=multivalent repression) functions of the *ilv1* gene. The advantage of using the yeast system, for studying regulatory phenomena, is that yeasts lend themselves well for intragenic complementation. Using many different *ilv1* mutants—impaired in threonine deaminase activity—intragenic complementation and fine structure analyses have been carried out.

Goldberger (*Science*, **183**, 810–816; 1974); Levinthal *et al.* (*Nature new Biol.*, **246**, 65–68; 1973) and Kasai (*Nature*, **249**, 523–527; 1974) have provided excellent background information about gene regulation. The first suggestion of an enzyme participating in its own regulation—by repression—was made by Vogel (in *The Chemical Basis of Heredity*, edit. by McElroy and Glass, Johns Hopkins Press, Baltimore 1957, page 276); it is also pertinent to note that the yeast system developed by Bollon and Magee (*Proc. natn. Acad. Sci. U.S.A.*, **68**, 2169–2173; 1971; *J. Bact.*, **113**, 1333–1344; 1973) offered the first evidence *in vivo* for the regulatory role of threonine deaminase, or for some form of the

ilv1 gene as Bollon shows in this issue. Of course, Umbarger and his many colleagues, as well as Hatfield's group, have provided a vivid picture of the role of *ilvA* (which specifies threonine deaminase) in multivalent repression in bacteria.

Although the *ilv1* gene product in yeast seems to be involved in multivalent repression, other elements are involved too. As already mentioned, Bollon and Magee noted that the involvement of leucine in multivalent repression may be unique (compare Levinthal *et al.*, 1973) and they suggest that leucine may function in repression by way of leucyl-tRNA; thus the *ilv1* gene product may be only one component of the multivalent machinery. One vital feature of the yeast which may have been overlooked is that the genes specifying its various isoleucine-valine enzymes are found on different chromosomes (compare *ilvADE*, *ilvB* and *ilvC* in *Escherichia coli*).

The principal points of Bollon's work can be summarised as follows:

- A multifunctional gene (*ilv1*) has been analysed in detail in a eukaryotic organism for the first time.
- The *ilv1* product, threonine deaminase, catalyses the conversion of L-threonine → α -ketobutyrate in yeast.
- The regulatory role of the *ilv1* gene product is considered a positive effector for the derepression of the isoleucine-valine enzymes.
- Thus *ilv1* is truly 'multifunctional' with catalytic and regulatory parts being played by threonine deaminase.
- Intracistronic discrimination denoting the catalytic and regulatory functions of *ilv1* is presented.

GERARD A. O'DONOVAN

the 28S and the 18S sequences, and the 5' side of the point where cleavage takes place later to generate 32S RNA. The single methyl group present in 5.8S RNA is also present in 32S and 45S precursor RNAs; this is consistent with the idea that methylation is confined to rRNA sequences in the precursors. Furthermore, two other sites of modification contain pseudouridine; it is not yet confirmed that the modification is introduced into the precursor, although this seems likely. Modification at one of these sites may be incomplete. Future determination of whether the 5.8S sequence is contiguous with the 28S sequence in the precursor, or whether there is a space between them corresponding to a non-rRNA sequence, may help to decide upon models for processing and the possible implication of secondary structures or particular nucleotide sequences. Whether the 5.8S RNA sequence is noncovalently bonded to the 28S sequence in the precursor or takes up this association after maturation is another relevant question.

Another approach to defining the organisation and synthesis of RNA sequences is to describe their location in the genome. By hybridising *Xenopus* DNA with 5.8S RNA, Speirs and Birnsteil (*J. molec. Biol.*, **87**, 237-256; 1974) found that the relationship of 5.8S to 28S and 18S sequences seems to be similar to that in HeLa cells. When *Xenopus* DNA is fractionated, the rDNA containing the sequences coding for 28S and 18S rRNAs can be separated from the bulk of the genome by its distinct content of G-C base pairs, a technique used some time ago by Brown and Weber (*J. molec. Biol.*, **34**, 681-698; 1968) and Birnsteil *et al.* (*Nature*, **219**, 454-463; 1968) to show that 28S and 18S sequences alternate and each pair is separated from the next by a spacer. Speirs and Birnsteil find that the fraction of a density gradient hybridising with 5.8S forms a satellite with the density characteristic of rDNA. The conclusion that 5.8S coding sequences are interspersed with 28S and 18S sequences is suggested also by their observation that the nucleolate mutant of *Xenopus* (which lacks both the 28S and 18S genes) does not synthesise 5.8S RNA; nor does 5.8S RNA hybridise with DNA extracted from mutant cells.

Because DNA-RNA hybrids have a buoyant density different from that of denatured DNA, the extent of the density shift when DNA fragments are annealed with rRNA reveals the proportion of the fragment complementary to RNA. And in linkage experiments, the DNA hybridising with one rRNA can be tested for its ability to hybridise with the other. By using DNA fragments of different lengths, it is possible to follow the organisation

of sequences in DNA that code for these RNAs. Extending the previous experiments of this nature with 28S and 18S rRNA to 5.8S RNA, Speirs and Birnsteil observed a small density shift when DNA fragments of 8 and 3 times its length are hybridised with 5.8S RNA—the low density shift implies that 5.8S coding sequences are interspersed with other sequences rather than clustered together. Linkage experiments show that prehybridisation with 28S or 18S rRNA induces a large shift in the density of the fragments hybridising with 5.8S RNA; 18S rRNA causes a smaller shift than 28S rRNA, so that the 5.8S sequence must be closely linked to the 28S sequence and less closely related to the 18S sequence. Taken together with the analysis of HeLa rRNA precursors, these results suggest that the 5.8S sequence lies between the 28S and 18S sequences in the genome. The model which Speirs and Birnsteil present for the rRNA sequences in the genome postulates a small separation between the 3' end of the 28S sequence and the 5' end of the 5.8S sequence, with another separation between the 5.8S and 18S sequences.

The role of the 'transcribed spacer' regions which separate the sequences constituting the mature rRNAs is not clear; it is tempting to speculate, however, that it is concerned with folding of the rRNA regions or their interactions with proteins during maturation. Perhaps against this model is the observation that the mature RNA sequences are very similar in length in, for example, *Xenopus* and HeLa cell, but the nontranscribed spacer lengths are very different. And in *Escherichia coli*, although the bacterial precursors are only slightly larger than the mature RNA molecules, ribosome assembly seems to take place perfectly well with isolated 23S and 16S rRNAs. A second type of spacer, the 'nontranscribed spacer', separates the precursor-coding sequences in nucleolar DNA and its function also is obscure, although recent experiments encourage the speculation that these sequences may in some way be concerned with the maintenance of identity in all the repeated rRNA sequences in the genome.

BENJAMIN LEWIN

New 30S ribosomal assembly map

from a Correspondent

THE updated version of Nomura's *Escherichia coli* 30S ribosomal "assembly map" (Held, Ballou, Mizushima and Nomura, *J. biol. Chem.*, **249**, 3103; 1974) raises two interesting points. First, of course, the additions to the map are themselves important, particu-

larly the inclusion of protein S12, which was absent from the original map (Mizushima and Nomura, *Nature*, **226**, 1214; 1970) and which is now receiving more and more attention (see for review Pongs, Nierhaus, Erdmann and Wittmann, *FEBS Lett.*, **40** Suppl., 28; 1974). The role of S12 in the streptomycin effect has been widely investigated, and although mutations in S12 confer streptomycin resistance (see, for example, Ozaki, Mizushima and Nomura, *Nature*, **222**, 333; 1969), it seems that proteins S3 and S5 are the ones which actually bind the antibiotic (Schreiner and Nierhaus, *J. molec. Biol.*, **81**, 71; 1973). Furthermore, revertant mutants from streptomycin dependence to independence show alterations in proteins S4 and S5 (Hasenbank, Guthrie, Stöffler, Wittmann, Rosen and Apirion, *Molec. gen. Genet.*, **127**, 1; 1973). This suggests a strong relationship between proteins S5 and S12, and it is therefore gratifying to find an interaction between these two proteins in the new assembly map.

Second, there is the question of which proteins are RNA-binding. The evidence presented by Held *et al.* that S17 (which now incidentally has become a separate entity from S16, the two proteins being treated as one in the original assembly map) can specifically bind to 16S RNA under reconstitution conditions is convincing. But in view of the controversy (discussed in detail by Held *et al.*) which has occurred over this protein and also S13, it is perhaps worthwhile to consider precisely what the term 'RNA-binding protein' means. The term normally defines proteins which can bind singly to ribosomal RNA under reconstitution conditions. The reconstitution buffer is necessary to obtain a specific interaction, but it must be remembered that this is a high salt buffer which reduces electrostatic interactions. This has the effect not only of preventing non-specific interactions, but also of weakening the specific RNA-protein interaction. Held *et al.* say that "it is conceivable that proteins other than the initial binding proteins also interact with 16S RNA in the finished ribosome structure". Perhaps it would be more appropriate to say that (in a particle which is two-thirds RNA, and whose proteins are almost all basic) it is almost inconceivable that other proteins do not interact with the RNA in the final structure.

This has of course been suggested already (see, for example, Lutter, Bode, Kurland and Stöffler, *Molec. gen. Genet.*, **129**, 167; 1974), although few people would go as far as Cox and Bonanou (*Biochem. J.*, **114**, 769; 1969) in arranging all the proteins in neat rows with identical RNA environments. It seems likely that the conclusion will be that in physiological salt conditions

the proteins have a widely varied but positive interaction with the RNA, with no sharp distinction between "binding" and "non-binding" proteins; the very existence of the controversy over the specificity of S17 and S13 binding supports this view.

Organic pollutants in the sea

from a Correspondent

THE requirements of industry and of agricultural practice have in recent years greatly enlarged the search for and use of a variety of classes of organic compounds which in large quantities eventually reach the sea. The nature, origin, dispersal persistence and fate of some of the more commonly occurring pollutants including halogenated hydrocarbons, organic heavy metal compounds and crude oils were reviewed at a discussion meeting organised by the Royal Society on July 4-5.

N. S. Thom and A. R. Agg (Water Research Centre, Stevenage) cited more than 200 substances believed to be significant pollutants of water in the United Kingdom, and C. R. Pearson and G. D. McConnell (ICI Ltd, Brixham and Runcorn) reviewed a range of industrial hydrocarbons in widespread use. It seemed from the papers of E. D. Goldberg (Scripps Institution, La Jolla) and J. E. Portmann (Fisheries Laboratory, Burnham-on-Crouch) that although the input of both DDT and dieldrin into the oceans of the northern hemisphere may have passed its peak, the output is increasing in the equatorial regions and southern hemisphere and world production of organochlorine pesticides is increasing. Although, as Pearson and McConnell pointed out, the many kinds of chlorinated hydrocarbons derived from C_1 and C_2 hydrocarbons used as intermediates in further manufacture or as solvents and carriers are not unexpectedly dispersed to the sea substantially through the atmosphere, heavier synthetic halogenated hydrocarbons such as PCBs and DDT residues may similarly be transported as gas molecules or adsorbed on airborne dust. Goldberg and Portmann each suggested a 25% transference to the oceans by these means.

Within the sea persistence of organic pollutants varies greatly according to their chemical stability, susceptibility to biodegradation and the routes and terminal situations of their passage. Half lives varying from a few hours (for example, CCl_4) to days or weeks (EDC tars deriving from vinyl chloride production) to years (for example, PCBs, DDT, aromatic compounds of high carbon number) were cited by S. Jen-

sen (Wallenberg Laboratory, Stockholm), R. Lange (Odense University) and E. D. S. Corner (Marine Biological Association, Plymouth) among other speakers as examples of varying persistence.

G. Eglinton (University of Bristol) showed a film demonstrating a newly developed computerised gas chromatography-mass spectrometry system used for the determination and assay of pollutants in coastal muds, a system which may prove to be useful also in determining the natural occurrence of organic compounds in muds deposited in pre-industrial times.

The uptake of organic pollutants by marine organisms and their levels of occurrence and sites of accumulation were discussed by several speakers. Their differential absorption by lipids was stressed and Portmann made the point that although many measurements had been made of the concentrations of the more persistent compounds in a variety of organisms of the higher trophic levels, little was known of transfers at lower trophic levels, for example in the grazing of phytoplankton by zooplanktons. Corner gave an account of work in progress on the utilisation, transformation and breakdown of fossil fuel hydrocarbons by marine crustaceans, a subject of particular interest in studies of the effects of oil spills. D. E. Hughes and P. McKenzie (University College, Cardiff) reported laboratory and field experiments indicating that about 40-90% of oil may be degraded by microbial attack; alkanes and other saturated compounds are more readily degraded than aromatic and heterocyclic compounds. A. J. Van Benekom (Netherlands Institute for Sea Research, Texel) reported on some consequences of discharges from the Rhine on the chemistry and plankton production of coastal water of the Southern Bight of the North Sea. Diatom growth was at times inhibited and the general level of production was unusually low and subject to irregular peaks. Blooms of *Phaeocystis* and possibly other toxic flagellates seemed to be favoured by these conditions.

New model of lunar interior

from Peter J. Smith

ACCORDING to Toksöz *et al.* (*Science*, **176**, 1012; 1972), the Moon has a 50-60 km thick crust in the eastern part of Oceanus Procellarum; and Nakamura *et al.* (*Science*, **181**, 49; 1973) concluded that the deep lunar interior below a depth of about 1,000 km is probably partially molten. But what is the state of the Moon between these

two extremes, in the mantle which accounts for the major part of the lunar volume? The complete answer to this question is not yet available, although Nakamura *et al.* (*Geophys. Res. Lett.*, **1**, 137; 1974) have now moved some way towards it in reporting new seismic data from the four Apollo seismic stations still in operation.

Nakamura and his colleagues have attempted to determine both P and S wave velocities throughout the lunar mantle from large meteoroid impacts, high frequency teleseismic events and deep moonquakes. The observed P wave velocity shows a systematic variation with epicentral distance, indicating that the subcrustal region cannot have a constant velocity. For example, P wave arrival times at distances greater than 70° are delayed by 10 s with respect to those expected from data at shorter ranges—an offset which could arise from a negative velocity gradient in the upper few hundred kilometres of the mantle, from a small stepwise decrease in velocity at a depth of the few hundred kilometres, or from a combination of the two.

For a negative velocity gradient, the travel-time curve would be continuous between 50° and 70°; and on this assumption, Nakamura *et al.* calculate that the P wave velocity would decrease from about 8.1 km s⁻¹ at the top of the mantle to about 7.8 km s⁻¹ at a depth of about 500 km, followed by a slight increase. For a stepwise decrease, the travel-time curve would be discontinuous with a shadow zone somewhere between 50° and 70°; and calculations put the minimum depth of the step at 200-300 km and its velocity contrast at 0.3 km s⁻¹. For a combination situation, the velocity gradient and velocity contrast would be smaller than those I have given. Unfortunately, the available data are too uncertain to enable a decision to be made about which of the three cases actually obtains, although Nakamura and his colleagues seem to favour the combination.

More certain (though based on a single data point) is a very large delay in P wave arrival at 168° which, if subsequently confirmed, would suggest that the Moon has a low velocity core. The present data put a limit of 170-360 km on the radius of such a core and a limit of 3.7-5.1 km s⁻¹ on its P wave velocity. Also conspicuous is the near linearity of the S wave travel-time curve beyond distances of 90°, indicating a large, and apparently increasing, delay of S wave arrivals relative to P wave arrivals at greater distances. Possible explanations involve one or more of the following effects: refraction of waves by a large negative velocity gradient at about 300 km depth, diffraction of waves around a discontinuity at this depth, or penetration of

waves into a lower velocity zone below. In fact, calculations suggest that the S wave velocity decreases from about 4.7 km s^{-1} at the top of the mantle to about 4.4 km s^{-1} at 300 km, followed by a more rapid decrease to a value of $3.8 \pm 0.2 \text{ km s}^{-1}$. Below 800 km, S waves are highly attenuated.

From these and other results, the most up-to-date picture of the lunar interior is then as follows:

- Zone 1: crust. This uppermost zone is 50–60 km thick in the region of the Apollo 12 and 14 stations and has seismic velocities consistent with plagioclase-rich material. The top few hundred metres is highly pulverised.
- Zone 2: upper mantle. This zone is about 250 km thick and has a P wave velocity of about 8.1 km s^{-1} which probably decreases slightly with depth. The seismic data are consistent with mineral assemblages comprising olivines (mostly) and pyroxenes (partly). The temperature gradient at the top of this zone is calculated to be $2\text{--}5^\circ \text{C km}^{-1}$.
- Zone 3: middle mantle. This is a zone with reduced S wave velocity and extends from 300 km to 800 km. Deep moonquakes occur at the base of it.
- Zone 4: lower mantle. This zone below 800 km is marked by high S wave attenuation and is possibly partially molten (as the terrestrial asthenosphere).
- Zone 5: core. This zone has a radius of 170–360 km and is marked by a greatly reduced P wave velocity. Molten?

Microclimate of open shade habitat

from Peter D. Moore

EXTREME habitats and the morphological and physiological adaptations necessary for life within them have always been more popular topics for study than have moderate conditions. It is becoming apparent, however, that immediate habitats, or ecotones, often have interesting attributes which make them worthy of special attention. An example of such a situation is provided by the study of open and shaded habitats.

For many years it has been conventional to classify plants into sun-demanding (heliophytes) and shade-requiring (sciophytes), and a great deal of research has been carried out both upon the physiological adaptation of these plants (for example, Björkman and Holmgren, *Physiologia Pl.*, **16**, 889; 1963; Björkman, *ibid.*, **19**, 854; 1966) and upon the light climates of shade habitats (for example, Anderson, in *Plant Photosynthetic Production*, edit. by Sestak, Catsky and Jarvis, Junk, The Hague, 1971). Little atten-

tion, however, has been given to intermediate situations, which can be termed 'open shade'.

A study of the open shade habitat from the microclimatic point of view has now been made by Stoutjesdijk (*Acta bot. neerl.*, **23**, 125; 1974). Surface temperatures on the north side of a patch of hawthorn (*Crataegus monogyna*) scrub in a Dutch sand-dune system were found to be as much as 10°C below those of ambient air. Although surfaces temperatures above ambient are commonplace, to find surfaces considerably below ambient at midday is extremely unusual and can only be explained in terms of the overall energy balance in these situations. At 11.30 h on a bright day in September, Stoutjesdijk found the surface temperature to be 9.1°C whereas ambient air was 15°C . Incoming radiant energy was in the form of diffuse solar radiation ($0.1 \text{ cal cm}^{-2} \text{ min}^{-1}$) and long wave radiation from the sky ($0.395 \text{ cal cm}^{-2} \text{ min}^{-1}$). Radiant energy loss was accounted for by reflection ($0.01 \text{ cal cm}^{-2} \text{ min}^{-1}$) and by long wave radiation ($0.523 \text{ cal cm}^{-2} \text{ min}^{-1}$). The net outcome of this situation is negative energy balance of $-0.038 \text{ cal cm}^{-2} \text{ min}^{-1}$, this being largely the result of the high long-wave radiation losses. The negative radiation budget is rather weak, however, and cannot fully account for the low surface temperature. The true energy budget is more strongly negative because of latent heat losses from the surface during the evaporation of dew; this explains the low surface temperatures.

This type of energy balance situation can occur only in open shade, for only here are long-wave losses large in comparison with gains and evaporation can take place at a rate sufficient to maintain high latent heat losses. Surface temperatures were found to be below ambient in daytime throughout the year, but differences were least in June and July (shading effects diminished) and greatest in late summer (strong shading and considerable dew formation).

Some work has been carried out on the influences of leaf canopies upon the spectral quality of light, but most of this has been concentrated on fairly dense canopies (see, for example, Federer and Tanner, *Ecology*, **47**, 555; 1966; Daynard, *Can. J. Bot.*, **47**, 1989; 1969; *Acta bot. neerl.*, **21**, 185; 1972). These studies have shown that the rate of visible to far-red radiation decreases considerably as shading increases. Measurements by Stoutjesdijk in his open shade habitat showed that there was a far better penetration of photosynthetically usable light ($<700 \text{ nm}$) than in the deep shade beneath hawthorn scrub.

Open shade habitats, then, provide

an interesting combination of physical conditions—low daytime temperatures (with consequent high relative humidities) and moderate photosynthetically-effective light levels. Undoubtedly some plant species characteristic of open shade habitats, such as, for example, *Mnium undulatum*, *Rhytidiadelphus triquetrus*, find such conditions to their liking. Some anomalous plant distributions may also be explicable in terms of this unusual combination of microclimatic factors. For example, it may be that the steep, north facing scarp slopes of the South Downs provide a similar microclimatic habitat to Stoutjesdijk's 'open shade'. In which case it might explain the persistence in such situations of montane bryophyte species, such as *Racomitrium lanuginosum*, which are known to require high humidities, fairly low temperatures and moderately high light intensities for their survival.

Nature of Hoag's object

by John Gribbin

It is now nearly a quarter of a century since Hoag discovered a remarkable astronomical object which appeared to be a "perfect halo" surrounding a diffuse nucleus. But only now is Hoag's object, as it has come to be known, receiving the attention which its peculiarity merits. According to O'Connell, Scargle and Sargent (*Astrophys. J.*, **191**, 61–62; 1974) the object is certainly worth investigating and "one of the more exotic possible interpretations" is that the ring is the image of a background galaxy produced by a gravitational lens effect.

Hoag's object is clearly visible on *Sky Survey* prints (at $\alpha = 15 \text{ h } 15.0 \text{ min}$; $\delta = +21^\circ 46'$) but it has not previously been studied in detail. The core of the object is a fuzzy circle $6''$ in diameter, and the surrounding blue ring or annulus has inner diameter $28''$ and outer diameter $45''$ with an axial ratio of 0.93 ± 0.05 . The ring is structureless, and there is no sign of connecting material bridging the gap between core and annulus.

In the study now reported by O'Connell *et al.* new information has been obtained from spectrograms taken with the 200-inch telescope and the Lick 120-inch. The observed redshift of $12,740 \text{ km s}^{-1}$ and an assumed Hubble constant of $75 \text{ km s}^{-1} \text{ Mpc}^{-1}$ imply a distance of 170 Mpc, corresponding to a linear diameter of 5 kpc for the core and inner and outer radii of 23 kpc and 37 kpc for the ring.

Almost all of the properties of the core seem to be in line with those expected for compact galaxies, but there seems little doubt that the ring is "an

independent structural component . . . and not simply the unobscured rim of a normal SO disk". Several other similar systems are known, and O'Connell *et al.* cite the examples of NGC6028, NGC2859 and IC5285. "There is no reason to suppose that radiation from these rings is anything other than direct starlight", and in the case of Hoag's object the radiation certainly cannot be reflected light from the core, since the ring is "at least" as luminous as the core.

The interpretation which seems to be favoured by O'Connell *et al.* involves gravitational encounters between galaxies which could initiate star formation in "trapped" rings; they point out that a pair of galaxies near Hoag's object on the sky could, if they are at the same distance as the object, have passed by it 10^8 to 10^9 yr ago, just right to account for the apparent age of the stars in the ring.

Merokeratins

from Peter Speakman

WOOL is a mixture of about 100 different proteins, but Haylett's group in South Africa have been able to purify several proteins with a high cysteine content and to show homologies in their amino acid sequences. Argument is now over whether these proteins have evolved from a repeating penta- or deca-peptide (Swart and Parris, *Nature*, **249**, 580; 1974). Lindley and Cranston have pointed out that because of the heterogeneity of proteins a new experimental approach is needed to supplement sequence studies in order to study the pattern of disulphide cross-links between proteins as they are arranged together in the fibre (*Biochem. J.*, **139**, 515; 1974).

Protein fragments which are very similar in molecular weight, dimensions and α -helix content have been prepared from mammalian epidermal keratin and from reduced wool by partial proteolysis, the method which was used to prepare the meromyosins and more recently, myosin subfragments 1 and 2. A sharp low-angle X-ray diffraction pattern from oriented films of the wool fragment showed that it could aggregate in a specific way into long, thin assemblies. These fragments from epidermis and reduced wool may be in the native conformation; and so studies of their internal structure and dimensions in solution and investigations of their specific aggregates, are beginning to give information about the conformation of the protein chains within the keratin macromolecular components, and about the mutual positions of the macromolecules in the fibre or tissue. Analogous studies of dissolved muscle proteins and their modes of aggrega-

tion, and of tropocollagen and its polymorphic aggregates have contributed to a very detailed understanding of muscle and connective tissue structure.

The small-angle X-ray diffraction pattern published from the CSIRO Division of Protein Chemistry in Melbourne shows that a wool keratin fragment can be made to form specific aggregates which are about 200 Å in diameter and greater than 2,000 Å long, with a longitudinal repeat of 160 Å (Suzuki *et al.*, *J. molec. Biol.*, **73**, 275; 1973). The method of preparing the fragment is interesting and relevant. Wool proteins are dissolved by reduction in a solution of a denaturing agent (8M urea). The thiol groups are blocked by reaction with iodoacetate ions, and the urea is removed by dialysis. The proteins (SCMKA) with a smaller proportion of cysteine residues and a higher α -helix content than the original wool are separated by fractional precipitation and purified by chromatography.

It is clear that some refolding of the SCMKA proteins, into conformations which are not completely flexible, takes place when the urea is removed, because a fairly large protein fragment (as well as small peptides) is produced when the SCMKA proteins are treated briefly with chymotrypsin. The fragment has a molecular weight of 41,000, a length of 170–200 Å measured in solution or 160 Å in the electron microscope, and a diameter of 20 Å. It has a higher α -helix content (80%) than the original SCMKA proteins (50%) and it is believed to consist of three chains (Crewther and Harrap, *J. biol. Chem.*, **242**, 4310; 1967; Dobb *et al.*, *J. Textile Inst.*, **64**, 374; 1973). A similar wool fragment has been prepared without using a denaturing agent (Hilburn *et al.*, *Biochim. biophys. Acta*, **214**, 245; 1970; Dilley *et al.*, Abstracts, British Biophysical Society Meeting, Leeds, April 1971). If wool is reduced at pH 10 (which itself may cause some denaturation) and treated with trypsin, a rod-shaped fragment, 200 Å long and 20 Å wide, molecular weight 55,000, with a higher α -helix content (64%) and a lower cysteine content than the original wool, can be separated from the digest.

An analogous fragment prepared by partial proteolysis of epidermal keratin protein is reported from Matoltz's laboratory (Skerrow *et al.*, *J. biol. Chem.*, **248**, 4820; 1973). It is not necessary to reduce disulphide crosslinks in order to extract protein from mammalian epidermis but a high or low pH is needed (in this case pH 2.6), which may again, cause some denaturation. The solution of epidermal protein in acid buffer is added dropwise to a trypsin solution maintained at pH 8.8, and a protein fragment can be separated from the digest, length 200 Å, molecular weight 46,000, which is 83% α -helical.

Polyacrylamide gel electrophoresis in denaturing conditions showed that the fragment consisted of three chains with approximately similar molecular weights.

The protein chains of SCMKA were denatured during the preparation, and therefore information about the structure of wool can only be inferred from the structure of the SCMKA proteolytic fragment, and from the mutual arrangement of the fragments in the specific aggregate, if partial or exact renaturation occurred when the denaturant was removed. Similarly, the other wool fragment and the epidermal protein fragment have been exposed to pH values which might cause denaturation. On the other hand, the similarity between the three fragments strongly suggests that undenatured or accurately renatured parts of the keratin structure have been prepared in these experiments. Their compositions and α -helix contents imply that they originate in the wool protofibril and the epidermal protofilament, but the low yield in each preparation (for example, less than 10% in the case of the wool fragment prepared without a denaturing agent) means that they may not represent the whole of these structures.

This work will encourage attempts to dissolve native proteins from epidermis or reduced wool without the use of proteolytic enzymes or denaturing agents, and the study of their structure in solution. Fairly extreme conditions of pH or temperature dissolve large quantities of keratin proteins but they may cause denaturation. Milder conditions are less likely to cause denaturation, but smaller amounts of protein dissolve and it may not be clear whether they are minor components or partly soluble major components. In both cases, even if the protein has a definite conformation in solution this will not necessarily be identical to the conformation adopted by the same protein in the fibre or tissue. A similar problem arose in collagen research in the 1950s. Acid or neutral buffer solutions will only dissolve small amounts of tropocollagen from calf skin, for example, but it was possible to show that the conformation of the protein chains in dissolved tropocollagen is the same as in intact connective tissue. The length of the tropocollagen molecule measured in solution was shown to be consistent with the dimensions of one of its specific aggregates (SLS) in the electron microscope; and the mutual arrangement of the tropocollagen molecules in another specific aggregate (quarter-stagger) was deciphered, and shown to be very similar to the arrangement in connective tissue. Experiments with the native fibrous protein in solution, and research with intact tissue dramatically confirmed each other.

3C236, DA240; the largest radio sources known

A. G. Willis, R. G. Strom and A. S. Wilson

Sterrewacht, Leiden, The Netherlands

A high resolution study has been made of faint and very extensive radio components associated with the galaxies 3C236 and DA240. Their respective linear dimensions of 5.7 Mpc and 2 Mpc are without precedent. Their properties are compared with those of other radio galaxies and the consequences for present models of the evolution of these objects are briefly discussed.

It is important for several reasons to determine the maximum size to which a radio source may evolve. First, the relativistic electrons in the radio components will suffer unavoidable energy losses by various processes as they move away from the associated optical object^{1,2}. These losses are likely to be severe for very old or large sources and it may be that the study of such objects will allow a choice to be made between the various modes of energy replenishment that have been suggested². Second, these sources might serve as probes of the intergalactic medium, for their structure is likely to be strongly influenced by it. Finally, radio components of large angular size can be mapped in detail to obtain much needed clues as to the physical processes occurring in them.

So we felt it essential to ascertain whether the apparent upper cutoff in radio source sizes at about 1 Mpc (refs 3, 4) is a real effect or largely a consequence of observational selection. We have begun a programme of observation at a wavelength of 49 cm with the Westerbork Synthesis Radio Telescope (WSRT) to search for very large sources

which had not been recognised as such in earlier observations. Such a search requires a telescope with good sensitivity, as well as a resolving power sufficient to both delineate the extent of large objects and reliably separate them from unrelated confusing sources. A telescope is most sensitive to extended emission at long wavelengths because of its greater beam area and the non-thermal spectra of the radio sources. The effective sensitivity of existing single dishes can be increased only marginally by observing at longer wavelengths because of the severe limitations imposed by confusion.

With an aperture synthesis instrument like the WSRT, however, we can take full advantage of the improvement expected from a lowering of the frequency. A change in observing wavelength from 21 cm to 49 cm renders the instrument ten times more sensitive to typical radio emission distributed over several synthesised beams. Confusion remains tolerable, with an average of one detectable source in about 200 beam areas, while the twenty baselines simultaneously obtained ensure a low level of 'grating response confusion'.

Source selection and first results

We have selected for study a number of confused regions listed in the catalogue of Bridle *et al.*³. Observing with 10' resolution at 21 cm, they were unable to decide whether the objects were composed of physically associated components, or unrelated sources. Here we report our first results; the sources 3C236 (1003+35) and DA240 (0744+55) are huge radio galaxies having overall sizes

Fig. 1 Contour map of 3C236 at 49 cm. The field centre, at RA 10 h 04 min, Dec. 35° 00', is marked by a cross. The dashed contour is at a level of -7.5 mJy and continuous contours are plotted at intervals of 5 mJy per synthesised beam area from 5 mJy to 20 mJy, 10 mJy from 20 mJy to 100 mJy, and 50 mJy from 100 mJy to 350 mJy. Continuous contours at the 500, 1,500, 3,000 and 4,500 mJy level are also plotted. Stripes extending approximately north-south from the central intense source are due to instrumental effects as discussed in the text. The three black ellipses represent intense background sources, the effects of which have been removed from the map.

Table 1 Observations of 3C236 and DA240

	3C236	DA240
Observation length (half days)	1	2
No. of spacings, increment (m)	20, 72	40, 36
Synthesised half-power beamwidth ($\alpha \times \delta$)	57'' \times 99''	57'' \times 69''
Grating ring radius ($\alpha \times \delta$)	24' \times 41'	47' \times 57'
R.m.s. noise (mJy)	~ 1.5	~ 1.0
Primary beam pattern half-power width	82'	

of 5.7 and 2.0 Mpc respectively (assuming Hubble's constant $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and an Einstein-de Sitter cosmology).

Early interferometric observations⁶ indicated that most of the emission from 3C236 was contained within a very compact source $< 3''$ in extent. Wilkinson⁷ resolved this source with a baseline of $112,300 \lambda$ at 1,423 MHz and found that two unresolved components separated by $1''$ in position angle 119° gave the best model fit to his data. Wyndham⁸ identified the source with a 16 mag elliptical galaxy. Examination of the Palomar Sky Survey (PSS) prints yields no evidence that the galaxy is in a cluster. Only a few 19 mag objects are visible nearby, and another 16 mag elliptical is present some $4'$ to the north-east. Sandage⁹ measured a redshift $z = 0.0988$ for 3C236 based on a single emission line identified with $[\text{O II}] \lambda 3727$. His accurate photometric data¹⁰ showed that 3C236 lies very close to the line of best fit in the Hubble diagram for radio galaxies. Bridle *et al.*⁵ found two radio components separated by $34'$ straddling the compact source. They pointed out that if all the radio emission were associated, the overall size could be as great as 8 Mpc.

The source DA240 was resolved by Bridle *et al.* into a double whose components were extended and separated by $17'$. Caswell and Wills¹¹ identified 4C56.16, the stronger eastern component, with a 15 mag galaxy, number 9-13-66 in the catalogue of Vorontsov-Velyaminov and Arhipova¹² (hereafter referred to as V-V). This galaxy shows weak emission lines and has a redshift $z = 0.0356$ (ref. 13). Our observations show that instead the galaxy to be identified with DA240 lies midway between the two components found by Bridle *et al.*

Observations and reduction

3C236 and DA240 were observed at 49 cm with the WSRT, a detailed description of which is given elsewhere¹⁴. It consists of 12 equatorially mounted 25-m parabolic dishes situated along an east-west line. Telescope parameters and information relevant to the present observations are summarised in Table 1. Phase stability of the 49-cm system during a twelve hour observing period is about $\pm 1^\circ$, and the gain stability is certainly better than $\pm 1\%$. In our experience, the detection of weak emission having a brightness 0.003 of the most intense peak on the map is feasible with the present system; in the 3C236 observation, which is particularly well calibrated, this value has been extended to almost 0.001.

Two major problems had to be overcome in analyzing the data. First, it was found that both sources contain extremely intense components more than one hundred times as bright as the surrounding emission. Since the inner sidelobes of the synthesised antenna pattern are about 4% of the main response, sidelobes from the intense structure initially masked the low-level radiation. Second, in the case of 3C236, grating rings from some parts of the source distorted the emission from other parts. We have therefore used the CLEAN technique¹⁵, in which structure in the map is iteratively decomposed into a set of point sources, the effects of which are then removed from the map using the antenna pattern with its sidelobes and grating rings. Subsequent convolution of the point sources with a 'clean' antenna pattern leads to a map free from the effects of the subsidiary responses.

The reception pattern of the individual paraboloids causes emission from regions far from the field centre to be attenuated. The maximum effect occurs at the outer edge of the western component of 3C236, whose brightness is reduced by 30%. Flux densities and other tabulated data have been corrected for this effect, but the contour maps have not.

Maps and basic data

A contour map of 3C236 is shown in Fig. 1. The source consists of two extended components on opposite sides of the intense compact source, with outer edges at distances

Fig. 2 A contour map of DA240 at 49 cm. The field centre, at RA 07 h 44 min 30 s, Dec. $55^\circ 55'$, is marked by a cross. The dashed contour is plotted at a level of -5.5 mJy and continuous contours are at levels of 0.5 mJy and 2.5 mJy per synthesised beam area, and then in steps of 5 mJy from 5 mJy to 60 mJy, 10 mJy from 60 mJy to 100 mJy, 25 mJy from 100 to 150 mJy, 50 mJy from 150 to 250 mJy and 250 mJy from 250 mJy to 1,500 mJy. The greatest contour is at a level of 1,600 mJy.

Table 2 Some basic data on 3C236 and DA240

*Assuming $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and an Einstein-de Sitter cosmology.

†The flux densities are derived assuming 3C147 has a 49-cm flux density of 37.78 Jy, from extrapolation of the data of Kellermann *et al.*¹⁷.

‡ α defined in the sense flux density \propto frequency α .

of 24' and 15' from it. The extension of the outer components along the line joining them and the precision of the collimation (lines from the two prominent outer peaks meet the central one at an angle of 179.5°) indicate the association suggested by Bridle *et al.*⁵ to be real. Basic data relevant to 3C236 (and DA240) are summarised in Table 2.

The contour map shows a number of spurious, predominantly radial features emanating from the central component, the most prominent of which are nearly vertical. These stripes are instrumental effects produced in the vicinity of intense point sources by small gain and phase fluctuations during the observation, and determine the dynamic range discussed earlier. The peaks beyond the south-east edge of the following component result from the same effect. Their narrowness and radial elongation are usually sufficient to distinguish such features from real structure.

The south-following component has three strong peaks near its south-east end. The brightest of these, with a maximum intensity of 364 mJy per beam area, is centrally located at the eastern end of the low brightness plateau. This component is resolved, except on its outer edge. We think it likely that the two other peaks are unrelated background sources for the following reasons. Both are unresolved and the southernmost one lies adjacent to, rather than within, the low brightness emission. Our polarisation data show the following component, including the main peak, to have significant linear polarisation; the two unresolved sources, however, are unpolarised. From the number of background sources stronger than 6 mJy in a typical WSRT field at 49 cm, we expect 3C236 to coincide, on average, with about 0.5 unrelated objects, which is not significantly different from the two suggested here. For the remainder of our discussion, the main peak will be assumed to define the eastern end of 3C236.

We find the position angle of the source axis to be 122.5°, very close to the 119° which Wilkinson⁷ found for his model of the intense central double source. Since Wilkinson's value has an error of about $\pm 2^\circ$, the alignment may well be exact. This alignment shows that the process responsible for the double structure, which spans a linear scale ratio $\sim 2,000$, has maintained its orientation for at least 10⁷ yr. It is also interesting that the position angle of the minor axis of the optical galaxy seems roughly coincident with the radio source axis.

The distribution of brightness in DA240 is shown as a contour map (Fig. 2) and as an intensity modulated radio photograph (Fig. 3), the latter being particularly suitable for the display of faint, extended regions. Like 3C236,

DA240 is dominated by a very intense source (4C56.16), so the map is slightly affected by limitations of dynamic range. Thus several faint stripes appear to radiate from 4C56.16, and there is a weak residual grating ring near RA07 h 43 min.

DA240 consists of two nearly circular diffuse components, each about 12' in diameter. These regions are more sharply bounded in the south than the north, suggestive of a gradient in the external gas density across the source. Each component has a dominant maximum, and these peaks are almost equidistant from an unresolved central component. These three peaks have widely differing intensities, the easternmost one (4C56.16) having a maximum surface brightness of 1.74 Jy per beam area. From its visibility curve at 49 cm, we find that 4C56.16 emits 1.4 Jy from a region smaller than 15". The westernmost peak is twenty times less intense than the 4C source and is fully resolved, even along its leading edge. Preceding the entire western component and clearly associated with it, is a faint elongated feature some 6' in length and 4' wide. The centre component has a flux density of 267 mJy at 49 cm and, according to our preliminary data, at 6 cm has an angular size less than 3" and a flux density of 115 \pm 10 mJy.

Fig. 3 An intensity modulated radiophotograph of DA240, produced on a rotating drum photo plot system designed by W. J. Jaffe. The declination scale is compressed by about 12% relative to the right ascension scale.

Fig. 4 A crosscut in position angle 122.5° along the major axis of 3C236.

We have identified the compact central source with an elliptical galaxy having a diffuse outer envelope (number 9-13-57 in the V-V catalogue). V-V gives the dimensions of the inner core as $30'' \times 24''$. Schmidt (private communication) has measured a redshift $z=0.0356$ for this galaxy.

On the north-east side of the intense component 4C56.16 there is an unresolved subpeak with an intensity of about 38 mJy which is coincident with the galaxy V-V 9-13-66, the object thought by Caswell and Wills¹¹ to be associated with 4C56.16 itself. The redshift ($z=0.0356$) given by Burbidge¹³ is exactly the same as that measured by Schmidt for V-V 9-13-57. V-V 9-13-66 is classified as "a flat galaxy whose arms have an indefinite direction of winding". The flux density implies a radio power of $1.5 \times 10^{22} \text{ W Hz}^{-1} \text{ sr}^{-1}$ at 49 cm, much stronger than that of normal spirals¹⁹. The tantalising question of whether V-V 9-13-66 is actually immersed in the eastern component of DA240 cannot be conclusively answered with the present data.

A ridge of emission extends from each outer component of DA240 towards the central one. The position angle of a line joining the end of each ridge near the central component is almost the same as the position angle of the major axis of the optical galaxy, giving the ridge system the shape of an open 'S'.

From the available data^{5,18} we have derived an integrated 178 MHz flux density of 22 Jy for DA240 which is well above the nominal completeness limit of the 3C survey. As shown by Bennett²⁰, however, the 3C observations are increasingly insensitive to sources whose angular size exceeds about $5'$. It is essential for workers deriving statistical properties of radio source samples to appreciate the inherent limitations of many source surveys in this respect.

Our observations also show that both 3C236 and DA240 have strong linear polarisation at 49 cm. Although the integrated polarisation of 3C236 is negligible, individual regions show degrees of polarisation up to 20%. The eastern peak is polarised by 10% but as we have already noted, the other two intense sources near it are unpolarised. Polarisations of up to 40% and possibly higher occur in the extensive low brightness regions of DA240. The intense unresolved structure in 4C56.16 is 22% polarised, and in its immediate surroundings similar values are found. DA240 has an integrated percentage polarisation at 49 cm of 8.3%, higher than previously found for any radio galaxy at this wavelength²¹. The polarisation of the central components, coincident with the optical galaxies are $< 0.4\%$ and $< 2\%$ for 3C236 and DA240 respectively.

Discussion

A remarkable feature of the 3C236 and DA240 maps, and the main reason that much of the structure has previously escaped detection, is the huge range of surface brightness. In 3C236 a ratio of more than 1,000:1 is found between the intense central source and the faintest emission in the south following component. A profile of intensity along the major axis of the source (Fig. 4) indicates these differences. Although DA240 does not display such an extreme disparity the peak intensity of 4C56.16 exceeds the average brightness of DA240 by more than a factor of 80. It is not yet possible to say whether these large variations in surface brightness, and the prominence of the central component at 49 cm, qualify 3C236 and DA240 as rare source types.

The ratio of the flux densities of the outer components and their relative distances from the optical galaxy are not unusual²² in these sources. It is, however, interesting to note that both outer components of 3C236 are well resolved transverse to the source axis, unlike the majority of 3C double sources when observed with a similar resolution²².

Table 3 Comparison of 3C 236, DA240, Cen A and Cyg A

Source	3C236	DA240	Cen A	Cyg A
Distance* (Mpc)	554	206	10	320

			3.1	3.2
			8.8	9.0
			1800	2000
			2.4×10^{-6}	1.9×10^{-6}
			3.0	3.0
			1.3×10^9	1.6×10^9

*Assuming $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and an Einstein-de Sitter cosmology.

†Minimum energy estimates have been made assuming the energy of cosmic ray protons to be negligible. If the energy in protons exceeds that in electrons by a factor of 100, the minimum energies and the equipartition magnetic field strengths must be multiplied by 13.9 and 3.7, respectively.

Table 4 Minimum energies (U_{\min}), equipartition magnetic fields (B_{eq}), thermal electron densities (n_e) and masses (M) of selected regions

Source	Region	U_{\min}^* (erg)	B_{eq}^* (gauss)	n_e (cm^{-3})	M (M_{\odot})
DA240	Intense eastern compact component	1.3×10^{58}	2.4×10^{-6}	$< 6 \times 10^{-5}$	$< 8 \times 10^8$
DA240	Extended eastern low brightness area	1.6×10^{59}	5×10^{-7}	$< 2.4 \times 10^{-5}$	$< 1 \times 10^{11}$
3C236	Eastern head	3.3×10^{58}	2.2×10^{-6}	$< 7 \times 10^{-5}$	$< 1.7 \times 10^9$

*Minimum energy estimates have been made assuming the energy of cosmic-ray protons to be negligible. If the energy in protons exceeds that in electrons by a factor of 100, the minimum energies and the equipartition magnetic field strengths must be multiplied by 13.9 and 3.7, respectively.

DA240, also, has unusual features. In many respects—the relaxed nature of the large outer components, the 'S'-shaped ridge linking the brighter peaks—the source is reminiscent of Centaurus A (ref. 23). It may be significant that Centaurus A is also a large source exceeding 1 Mpc in length. Like 3C236, Centaurus A has a compact double source well within the large outer components.

In Table 3 we present a number of derived properties for 3C236, DA240, Cen A and the powerful radio galaxy Cyg A (ref. 24). We have assumed that the components are prolate spheroids whose depths are equal to their width in the plane of the sky along the minor axis and that the energy in cosmic ray protons is negligible. Examination of Table 3 shows that DA240 and Centaurus A do, indeed, have many similar properties. Cyg A, a much smaller, very intense source, has a higher luminosity, energy density and magnetic field strength than the other three.

In columns 1 and 2 of Table 4 we show the minimum energies U_{\min} in the form of relativistic electrons and magnetic field, and the corresponding equipartition magnetic fields B_{eq} for two selected regions of DA240 and one of 3C236.

As we have already noted, both sources are strongly polarised at 49 cm. Stringent upper limits may therefore be placed on the thermal gas density in the sources, for high gas densities would cause depolarisation by differential Faraday rotation. Assuming the line of sight depths through the components to be equal to their size in the plane of the sky, and the magnetic field to take its equipartition value, we find the upper limits to the thermal density, n_e , given in column 3, while the corresponding masses are presented in column 4. The gas densities found are at most an order of magnitude greater than the cosmological density of 3×10^{-6} hydrogen atoms cm^{-3} , and could be very much less. Such low densities, and the large overall sizes of the sources have interesting implications for certain models of the evolution of extragalactic radio sources which we now discuss in turn.

De Young and Axford²⁵ proposed a dynamical containment mechanism in which the ram pressure of the intergalactic gas confines the radio emitting components. In the context of their model it has been suggested²⁶ that the extensive 'tails' of low brightness often seen to extend back towards the parent galaxy result from electrons which have diffused out of the compact outer components. Such a scheme does not seem applicable to DA240, for here the extended low brightness emission completely envelopes the compact regions. As the motion of the component is envisaged to be supersonic it is not clear how electrons could diffuse ahead of it. Of course, if the components were more or less stationary (and contained by some process other than ram pressure), the observed morphology could result. The ram pressure model may also be criticised on the grounds that it supposes the components to leave the galaxy with sizes not much smaller than their present ones. For 3C236, there is evidence from the double structure of the compact central source that the original component sizes are not bigger than 1 kpc. In the subsequent expansion to the observed diameter of ~ 150 kpc for the compact eastern component, adiabatic losses would decrease the flux by a factor of more than 10^9 . It is, therefore, necessary that energy in the form of magnetic field and relativistic particles

be distributed over volumes much larger than a galactic nuclear region in a loss-less way, probably to be supplied to the components throughout most of their lifetimes.

A useable feature of the model is that the components are continually decelerated and eventually brought to a halt after which the source expands rapidly. Christiansen²⁷ has shown that a plasmon can travel a distance

$$D = M / (\pi \times 1.67 \times 10^{-24} n_s r^2) \quad (1)$$

before dispersing. Here M is the mass of the plasmon, r its radius and n_s the number density of the gas surrounding the component. Although equation 1 was derived assuming ram pressure containment, it yields an estimate of the distance travelled by the plasmon before it is strongly decelerated even if it is contained by other processes. This is because the plasmon must, in any case, experience a retarding force of (ram pressure) \times (cross-sectional area); r should then be interpreted as the component radius, suitably averaged over the source lifetime. In spite of uncertainty in this radius, it is interesting to apply equation 1 to the eastern component of 3C236 and so derive an upper limit to n_s by taking D and r as their present observed values and the upper limit to M from Table 4. We find $n_s < 10^{-6} \text{ cm}^{-3}$. If the source axis is not in the plane of the sky, the limit becomes correspondingly lower. In spite of this low density, the fact that the component leading edge is sharper than the trailing one suggests an interaction with an external gas. If the eastern component in 3C236 is, in fact, confined by ram pressure, $n_s > 3.6 \times 10^{-8} \text{ cm}^{-3}$, assuming the component velocity $v < 0.08c$ (ref. 28).

Gull and Northover²⁹ have proposed an elegant mechanism for the propulsion and confinement of radio components by a circumgalactic medium. The radially decreasing density of the medium, maintained by the galactic gravitational field, causes the components to 'float' away from the centre. The model seems, however, to be inapplicable to 3C236 and DA240 for several reasons. The most telling of these are the long component travel times ($\sim 10^{10}$ yr) and the difficulty of maintaining sufficient density gradients over the distances involved. Similar difficulties have been noted for Cyg A (ref. 24); for these giant sources they are even more severe.

Further observations of 3C236 and DA240 with the WSRT at 6 cm and 21 cm have either been planned or are already in progress. A presentation of these results and a full discussion of their implications will follow. We have also begun observations of other candidate objects, for it seems most improbable that these two are the only radio sources of moderate strength whose large scale structure has been overlooked. Before long we may know if 3C236 is atypical, or whether it must relinquish its distinction of being the largest known object.

A.G.W. thanks the National Research Council of Canada for a postdoctoral fellowship. A.S.W. is supported by a Royal Society European Program Fellowship. We thank Professor H. van der Laan for advice. Drs R. G. Bingham and D. Allen of the Royal Greenwich Observatory and Professor M. Schmidt of the Hale Observatories obtained spectra of V-V 9-13-57. We thank Dr G. K. Miley for comments and W. Jaffe and H. Kleibrink for help with the data reduction.

The Westerbork Synthesis Radio Telescope is operated by the Netherlands Foundation for Radio Astronomy with the

financial support of the Netherlands Organisation for the Advancement of Pure Research.

Fine structure analysis of a eukaryotic multifunctional gene

Arthur P. Bollon

Department of Biochemistry, University of Texas, Southwestern Medical School, Dallas, Texas 75235

The ilv 1 gene of Saccharomyces cerevisiae contains functions associated with both structural and regulatory genes and therefore is termed a multifunctional gene. The ilv 1 gene product catalyses the first step in isoleucine biosynthesis and is involved in repression of the isoleucine-valine pathway. The intracistronic discrimination of the two functions is presented.

IN spite of considerable progress in the understanding of the underlying molecular mechanisms involved in the regulation of gene expression in prokaryotes¹, such mechanisms remain obscure in eukaryotes. Although several approaches for studying eukaryotic control mechanisms have involved animal systems², much information about eukaryotic regulatory phenomena has been obtained from studies with fungi. Work with *Neurospora* has revealed several complex forms of regulation, for example, enzyme aggregation^{3,4} and compartmentation⁵, and *Saccharomyces* has been the subject of several elegant studies⁶⁻⁹. Nevertheless, a regulatory macromolecule like a repressor protein involved in the control of gene expression in eukaryotic organisms remains to be identified and characterised.

There is evidence from *in vivo* studies that threonine deaminase or some form of the *ilv 1* gene product, is involved in multivalent repression of the isoleucine-valine enzymes, probably functioning as a positive effector. Altered repression of the isoleucine-valine biosynthetic enzymes was observed in *Saccharomyces cerevisiae* MAR-33 (ref. 10), with a mutation in or closely linked to the *ilv 1* gene which renders threonine deaminase 100 times less sensitive than the wild type to isoleucine inhibition^{11,12}. The isoleucine-valine biosynthetic enzymes from MAR-33 are fully derepressed when the strain is grown on minimal medium while normally only partial derepression is attained under these conditions^{11,12}. Altered regulation of the isoleucine-valine enzymes was observed also in strain D106-la, which contains a nonsense mutation in the middle of the *ilv 1*

gene^{11,12}. In D106-la, the isoleucine-valine biosynthetic enzymes fail to derepress when cells are grown in minimal medium or in a medium limited for isoleucine, a condition that normally leads to complete derepression. Magee and I have shown that the altered regulatory effects on the isoleucine-valine enzymes cosegregate with the desensitising threonine deaminase mutation in MAR-33 and the *ilv 1* nonsense mutation^{11,12}.

In vivo evidence for threonine deaminase or some form of the *ilv 1* gene product in multivalent repression of the isoleucine-valine pathway has been obtained also in bacteria in Umberger's laboratory^{13,14} as well as in that of Hatfield¹⁵, who suggested

Fig. 1 Biosynthetic pathway for isoleucine and valine in *Saccharomyces cerevisiae*. Threonine deaminase (EC 42116) is the first enzyme specific for the biosynthesis of isoleucine. The other four enzymes are involved in the biosynthesis of both valine and isoleucine. Repression of AHAS, reductoisomerase, dehydrase and transaminase B requires isoleucine, valine and leucine each at 5 mM. In *Saccharomyces cerevisiae*, the genes which code for the five different isoleucine-valine enzymes are on different chromosomes.

some role for threonine deaminase in repression¹⁶. In addition to the isoleucine-valine pathway, the involvement of a biosynthetic enzyme in repression of subsequent enzymes of the histidine pathway has been shown by Goldberger *et al.*^{17,18}.

The diversity of protein function became clearer with reports of proteins with several activities^{7,11,17}. I report here the analysis of the catalytic and regulatory functions of the *ilv 1* gene. I present evidence confirming the multifunctional nature of the *ilv 1* gene where by genetic and biochemical analyses, the intracistronic discrimination of some of the *ilv 1* regions associated with each function are assigned.

Catalytic function of *ilv 1*

Figure 1 shows one activity of the *ilv 1* gene product is the conversion of L-threonine to α -ketobutyrate, the first biosynthetic step leading to the synthesis of L-isoleucine. This catalytic activity is performed by threonine deaminase whose activity is 50% inhibited by 0.5 mM L-isoleucine and stimulated by 5 mM L-valine¹⁰. The threonine deaminase from *S. cerevisiae* contains two identical subunits of approximately 100,000 molecular weight^{10,19}.

Several strains of *S. cerevisiae* with mutations in the *ilv 1* gene, rendering threonine deaminase catalytically inactive²⁰, have been tested (Table 1). Each *ilv 1* allele represented in the table has been subjected to genetic fine structure analysis and the map is given in Fig. 2 (ref. 20). As Table 1 shows the *ilv 1* mutations 1, 101, 67, 117, 113 and 8 are adjudged to be nonsense mutations by suppression studies²⁰, whereas suppressibility of the other *ilv 1* mutations has not been observed²⁰.

As Zimmerman²⁰ indicated, the genetic length of the *ilv 1* gene using the *ilv 1-41* and *ilv 1-8* alleles as its extremities is about 16 map units of induced mitotic recombination. Based on previous data^{21,22} one unit of recombination represents approximately 130 nucleotides. By these calculations the *ilv 1* gene product involved in catalytic function would have a molecular weight of approximately 100,000 which is consistent with a dimeric protein of approximately 200,000 molecular weight, as indicated above.

Threonine deaminase activity was found in extracts of several diploid strains each containing different pairs of *ilv 1* alleles. Intragenic complementation between various *ilv 1* alleles has been found by Zimmermann *et al.*²³. The diploid strains constructed by mating different haploid strains each containing various *ilv 1* mutations, as well as a diploid strain containing two wild type *ilv 1* genes, are given in Table 2.

Fig. 2 Fine structure map of the *ilv 1* gene. The alleles above the line are of the nonsense type.

Extracts were prepared from the various diploid strains and the specific activity of threonine deaminase was determined as before^{10,12}. In addition, the sensitivity of the diploid threonine deaminase to inhibition by 1.0 mM and 100 mM L-isoleucine was determined. Table 2 shows threonine deaminase with a specific activity of 3.21 (μ mol of product formed per 20 min per mg of protein) was found in extracts from the diploid containing two wild type *ilv 1* genes. An unexpectedly high threonine deaminase specific activity of 1.23 was found for the diploid containing the *ilv 1-51* and *ilv 1-79* alleles, which is 40% of the specific activity found in the wild type diploid. Table 2 shows the threonine deaminase obtained from the diploid containing the *ilv 1-51* and *ilv 1-79* alleles was not inhibited by 1.0–100 mM L-isoleucine which inhibits *ilv 1*⁺ \times *ilv 1*⁺ wild type threonine deaminase. As previously reported, 100 mM L-isoleucine inhibits the threonine deaminase obtained from strain MAR-33 harbouring a mutation in *ilv 1* (or closely linked to it) which renders the enzyme 100 times less sensitive to isoleucine inhibition. Table 2 shows of the other diploids tested for threonine deaminase activity, that containing the *ilv 1-48* and *ilv 1-77* alleles had a threonine deaminase specific activity of 0.31 which seemed to be sensitive to inhibition by 1.0 mM isoleucine. Neither the diploid containing the *ilv 1-48* and *ilv 1-82* alleles nor that containing the *ilv 1-51* and *ilv 1-82* alleles had detectable threonine deaminase activity.

Therefore, in addition to showing several strains containing *ilv 1* mutations rendering threonine deaminase either catalytically inactive or less sensitive to isoleucine inhibition, the use of diploids containing different *ilv 1* alleles has facilitated, by intragenic complementation, the *in vivo* construction of threonine deaminase molecules with altered properties for isoleucine inhibition.

Regulatory function of *ilv 1*

As previously indicated, in addition to catalytic activity, some form of the *ilv 1* gene product must be involved in multivalent repression of the isoleucine-valine biosynthetic enzymes,

Table 2 Threonine deaminase specific activity in diploid strains

Diploid genotype	L-isoleucine added (mM)		
	0	1.0	100
<i>ilv 1</i> ⁺ \times <i>ilv 1</i> ⁺	3.21	0	0
<i>ilv 1-51</i> \times <i>ilv 1-79</i>	1.23	1.14	1.29
<i>ilv 1-48</i> \times <i>ilv 1-77</i>	0.31	0	0
<i>ilv 1-48</i> \times <i>ilv 1-82</i>	0		
<i>ilv 1-51</i> \times <i>ilv 1-83</i>	0		

The threonine deaminase was assayed as previously described¹⁰ in the absence of L-isoleucine and in the presence of 1.0 mM and 100 mM L-isoleucine. Specific activity is expressed as μ mol of α -ketobutyrate formed per 20 min per mg of protein. Diploid strains were grown in minimal medium and extracts were obtained for the threonine deaminase assay, as previously described^{10,12}.

probably acting as a positive effector^{11,12}. This function is designated the '*ilv 1* regulatory function'. Evidence for altered *ilv 1* regulatory function was sought in various strains containing different *ilv 1* mutations as well as in the diploid strains constructed by mating the various haploid *ilv 1* auxotrophs.

I analysed the *ilv 1* regulation function by two approaches. First, determinations were made of the acetohydroxy acid synthase (AHAS) specific activity obtained from the various *ilv 1* auxotrophs and diploid strains grown in minimal, repressing and isoleucine limiting medium (Table 3). Second, the AHAS differential rate of synthesis was determined in cultures which had been transferred from repressing medium to isoleucine limiting medium (that is kinetics of escape from repression).

Two major conclusions can be drawn from Table 3. First, the *ilv 1* regulatory function is altered in strains containing the *ilv 1* nonsense alleles *ilv 1-1* and *ilv 1-101*. Second, altered

The repressing medium used is minimal salts medium plus L-isoleucine, L-valine and L-leucine, each at 5 mM^{12,24}. Minimal medium consisted of minimal salts medium as previously described^{10,22}. Where isoleucine was necessary for growth, a nonrepressing concentration of 2 mM L-isoleucine was added^{12,24}. Isoleucine limiting medium consisted of minimal salts medium plus 2.5 mM L-isoleucine and 20 mM L-valine which competes for isoleucine utilisation^{12,24}. AHAS was assayed in toluenised cells as previously described^{12,24}. Its specific activity is expressed as μmol of product produced per 20 min per mg of protein. MD11 is a strain wild type for the *ilv 1* gene. M21 contains a nonsuppressible *ilv 1* mutation which renders threonine deaminase catalytically inactive. In the cases where standard deviations are represented, four determinations were done.

* Ratio of AHAS activity obtained from cells grown in isoleucine limiting medium (ILM) compared with cells grown in repressing medium (RM).

ilv 1 regulatory function is not observed in strains containing the *ilv 1* nonsense alleles, *ilv 1-67*, *ilv 1-113*, *ilv 1-117*, and *ilv 1-8*.

As Table 3 shows, AHAS was derepressed approximately 2.5-fold when the normally regulated strains MD11 and M21^{11,12} were grown on minimal medium compared with repressing medium: the ratio of AHAS specific activity of M21 cells grown in isoleucine limiting medium compared with repressing medium was 6.4. Similar results were obtained for all strains containing the various *ilv 1* alleles including the *ilv 1-67*, *ilv 1-113*, *ilv 1-117* and *ilv 1-8* nonsense alleles, with the exception of strains containing the *ilv 1-1* and *ilv 1-101* nonsense alleles where no AHAS derepression was observed when cells were grown in minimal or isoleucine limiting medium. The ratio of AHAS specific activity when strains containing either the *ilv 1-1* or *ilv 1-101* alleles were grown on isoleucine limiting medium compared with repressing medium was close to unity. Since the AHAS specific activity obtained from strains containing the *ilv 1-1* or *ilv 1-101* alleles grown in repressing medium was similar to that obtained for the normally regulated strains MD11 and M21, unity represents a failure to derepress

under minimal and isoleucine limiting conditions.

Since only the *ilv 1-1* and *ilv 1-101* nonsense mutations and not the *ilv 1-8*, *ilv 1-67*, *ilv 1-117* and *ilv 1-113* nonsense mutations affect the *ilv 1* regulatory function, one might conclude that the *ilv 1* region excluded by the *ilv 1-1* and *ilv 1-101* nonsense mutations are needed for regulatory function whereas the regions excluded by the other *ilv 1* nonsense mutations are not.

These results were substantiated by examining the differential rate of synthesis of AHAS by the second method in cultures transferred from repressing medium to isoleucine limiting medium^{11,12}. Figure 3 gives the differential rate of AHAS synthesis in M21, which is normally regulated for the isoleucine-valine enzymes—it was 0.19. The AHAS differential rate in the strain containing *ilv 1-1* was 0.017 and in the strain containing *ilv 1-101*, 0.021. As Table 4 shows AHAS differential rate of 0.02 was obtained when M21 was grown in repressing medium. The low AHAS differential rate obtained from the strains containing the *ilv 1-1* and *ilv 1-101* alleles grown on isoleucine limiting medium therefore, reflects lack of derepression. Also Table 4 shows the strains containing the other nonsense alleles, *ilv 1-113*, *ilv 1-8* and *ilv 1-67*, strains containing suppressors for the *ilv 1-1* and *ilv 1-101*, *ilv 1-1 SUP* and *ilv 1-101 SUP* and strains containing the nonsuppressible *ilv-1* alleles 51 and 79 gave AHAS differential rates of synthesis comparable with the normal value obtained with M21.

Figure 3 also shows that the increase in the differential rate of synthesis of AHAS was inhibited by 50 $\mu\text{g ml}^{-1}$ of cycloheximide, which inhibits protein synthesis. Thus the increase in activity required protein synthesis and probably represented synthesis of new enzyme. In addition, since the level of AHAS after inhibition of protein synthesis remained constant for 4 h, no substantial degradation of AHAS occurred within the 4 h period.

The altered *ilv 1* regulatory function and the *ilv 1-1* and *ilv 1-101* mutations cosegregate in four tetrads tested. As Table 3 shows, both catalytic and regulatory function was restored when suppressors for the *ilv 1-1* and *ilv 1-101* nonsense mutations were present. In addition, the altered *ilv 1* regulatory

Table 4 Differential rate of AHAS synthesis in *ilv 1* auxotrophs

* μmol of product produced per 20 min per 10^6 cells.

† Differential rate of synthesis for AHAS when strain M21 is grown on repressing medium.

Strains were transferred from repressing medium to isoleucine limiting medium as described for Fig. 3.

function resulting from the *ilv 1-1* and *ilv 1-101* mutations was recessive to wild type (Table 5). When a strain containing either the *ilv 1-1* or *ilv 1-101* mutations was mated with a strain which was *ilv 1⁺; ilv2⁻*, and the resultant diploid strain was grown on minimal medium, the AHAS specific activity was derepressed 2.5 times more than the normal repressed level. These results suggest that the *ilv 1* gene product is necessary for derepression of the isoleucine-valine enzymes.

Fig. 3 Cells were grown in 50 ml of repressing medium to about 5×10^7 cells per ml, centrifuged, washed and diluted five times into 250 ml of minimal medium plus 20 mM valine and 2.5 mM isoleucine (isoleucine limiting medium). Samples of 50 ml were taken after 0, 2, 4, 6 and 8 h. Cells were made permeable by toluene and the AHAS was assayed as previously reported^{12,24}. The numbers 2 and 4 shown after each point represent AHAS activity 2 and 4 h after the addition of 50 μ g of cycloheximide. Open triangles represent strain M21, closed triangles represent the strain containing the *ilv 1-1* allele and the open circles represent the strain containing the *ilv 1-101* allele.

There is evidence^{11,12} that the isoleucine inhibition property of threonine deaminase is related to the *ilv 1* regulatory function. In a strain MAR-33, which contains a mutation in (or closely linked to *ilv 1*), the threonine deaminase is 100 times less sensitive to isoleucine inhibition¹⁰. When MAR-33 was grown on minimal medium, the AHAS as well as the other isoleucine-valine enzymes were derepressed approximately six-fold, attaining a specific activity usually obtained only under isoleucine limiting conditions. If 5 mM L-isoleucine was added to the medium, the isoleucine-valine enzymes were derepressed only 2.5-fold which is usually attained when a wild type strain is grown on minimal medium^{11,12}. In another strain TIR-9 which also contains a mutation in *ilv 1* (or closely linked to it), the threonine deaminase is only ten times less

sensitive to isoleucine inhibition¹⁰. The levels of the isoleucine-valine enzymes when TIR-9 was grown under minimal conditions were like wild type. Therefore, it seems that a 100-fold but not a ten-fold isoleucine desensitisation of the threonine deaminase affects the *ilv 1* regulatory function.

Table 5 Recessivity of altered *ilv 1* regulatory function

Medium	Diploid genotype	Specific activity of AHAS
Minimal	<i>ilv 1-1 ilv 2⁺ × ilv 1⁺ ilv 2⁻</i>	0.123 ± 0.017
	<i>ilv 1-101 ilv 2⁺ × ilv 1⁺ ilv 2⁻</i>	0.112 ± 0.019
Repressing	<i>ilv 1-1 ilv 2⁺ × ilv 1⁺ ilv 2⁻</i>	0.041 ± 0.011
	<i>ilv 1-101 ilv 2⁺ × ilv 1⁺ ilv 2⁻</i>	0.047 ± 0.010

AHAS was assayed as previously described^{12,24}, and specific activities are expressed as μ mol of product produced per 20 min per mg of protein.

The *ilv 1* regulatory function was examined in the various diploid strains previously described, especially that which contains the *ilv 1-51* and *ilv 1-79* alleles which result in threonine deaminase desensitised to isoleucine inhibition (Table 3). In all diploids tested except one, the AHAS-specific activity was approximately 2.5 times greater when cells were grown in minimal medium compared with repressing medium. In the diploids strain containing the *ilv 1-51* and *ilv 1-79* alleles, the AHAS specific activity was five times greater when cells were grown in minimal media compared with repressing media. This increased derepression of the AHAS when the diploid strain containing *ilv 1-51* and *ilv 1-79* alleles was grown on minimal media further indicates the interrelationship of the isoleucine inhibition site of the *ilv 1* product, and the *ilv 1* regulatory function.

Multifunctional map of *ilv 1*

A summary of the effects of the various *ilv 1* mutations on *ilv 1* catalytic and regulatory function is represented in Fig. 4. The results are represented as a multifunctional map which consist of three representations of the *ilv 1* gene each corresponding to a different property of the *ilv-1* gene product and each containing the *ilv-1* alleles causing defects in the corresponding *ilv 1* function.

As Fig. 4 shows, the *ilv 1-1* and *ilv 1-101* nonsense alleles concordantly affect both catalytic and regulatory function, whereas both functions are discordantly affected by the *ilv 1-113*, *ilv 1-117*, *ilv 1-67*, and *ilv 1-8* nonsense alleles where only the catalytic function is affected. In addition, the other nonsuppressible *ilv 1* alleles did not affect *ilv 1* regulatory function.

These results suggest that the *ilv-1* regions affected by the *ilv 1-117*, *ilv 1-113*, *ilv 1-67* and *ilv 1-8* nonsense mutations are not needed for regulatory function but are necessary for catalytic function. On the contrary, *ilv 1-1* and *ilv 1-101* nonsense mutations affect *ilv 1* regions needed for both regulatory and catalytic functions. In addition, these results represent the strongest indication that the regulatory function actually is within the *ilv 1* gene and not in an adjacent regulatory region.

In addition, as seen in Fig. 4, alleles *ilv 1-51* and *ilv 1-79* do not affect *ilv 1* regulatory function in haploid strains. Nevertheless, regulatory function is altered in a diploid strain containing both *ilv 1-51* and *ilv 1-79* alleles, where intragenic complementation results in restoration of threonine deaminase activity that is insensitive to isoleucine inhibition. These results are consistent with the report of a concordant affect on isoleucine inhibition and regulatory function in strain MAR-33 (refs 11, 12). Preliminary data indicate that MAR-33 has a

Fig. 4 Multifunctional map of the *ilv I* gene. Each representation of the *ilv I* gene corresponds to one of the *ilv I* functions which are represented at the left of the corresponding cistron. Only the alleles which result in altered function are represented. The alleles above the line are of the nonsense type.

mutation near the middle of the *ilv I* gene and that it is not suppressible (my unpublished data).

In conclusion, the results presented here strongly indicate that the *ilv I* gene is multifunctional, coding for a product which functions in the catalysis of L-threonine to α -keto-butyrate, as well as being a positive effector in the derepression of the isoleucine-valine enzymes. I have found correlation between the isoleucine inhibition property of threonine deaminase and *ilv I* regulatory function. Furthermore, there is intracistronic discrimination of the *ilv I* catalytic and regulatory functions. Apparently the regulatory function of the multifunctional *ilv I* gene represents an example of a eukaryotic regulatory gene which has been identified and partially characterised both genetically and biochemically.

I thank Dr Fritz Zimmermann for *ilv I* auxotrophs and helpful discussions, and Dr P. T. Magee for several strains and for useful discussions. I thank Melvin Dews for technical assistance. This work was supported by a grant from the National Institutes of Health.

letters to nature

Cosmogony of the asteroidal belt

WE have to derive the state of partial corotation in a way which, by being very simple, stresses its character as a basic state in cosmic plasma dynamics. We also substitute the mass density (m, a) for the number density (n, a) in the plot of asteroids, as a function of their semimajor axis a . This gives a better definition to the limits of the main belt, and demonstrates more clearly that the asteroids—like the Saturnian rings—have condensed from a partially corotating plasma.

If a rotating body has an axisymmetric dipole field and is surrounded by a plasma, and if the electrical conductivity of the body and of the plasma is infinite, the plasma will rotate with the same angular velocity Ω as the body; the magnetic field lines are 'frozen-in'. This idealised model is, however, not applicable to cosmic problems because celestial bodies have gravitation, and the plasma is subject both to that and to the centrifugal force produced by the rotation¹⁻⁴. Moreover, the 'frozen-in' picture is seldom applicable in astrophysics⁴⁻⁷. The assumption of infinite conductivity is unrealistic, because electric fields parallel to the magnetic field play an important role^{8,9}. It is now evident that the magnetosphere is to a high degree uncoupled from the ionosphere¹⁰.

This means that instead of a plasma corotating with an angular velocity $\omega = \Omega$, we have typically a 'partial corotation' with $\omega < \Omega$ (refs 3 and 4). The rotational velocity is given by the condition that the centrifugal force, f_c , the gravitation, f_g , and the electromagnetic force, f_B , acting on a plasma element should balance each other, so that

$$f_c + f_g + f_B = 0 \quad (1)$$

(We assume that the plasma temperature is so low that pressure and diamagnetic effects can be neglected—see Fig. 1.) If M_c is the mass of the central body, κ the constant of gravitation, B the magnetic field deriving from a dipole with moment a, m the mass of a plasma element, I the current through it, and \mathbf{x}_0 a unit vector perpendicular to the axis, there is in a coordinate system (r, λ) in the meridian plane of the dipole:

$$f_c = \omega^2 m r \cos \lambda \mathbf{x}_0 \quad (2)$$

$$f_g = (\eta M_c m / r^3)(-\mathbf{r}) \quad (3)$$

$$f_B = I \times B \quad (4)$$

Fig. 1 Configuration of partial corotation. Equilibrium between gravitation f_g , centrifugal force f_c , and electromagnetic force $f_B = \mathbf{I} \times \mathbf{B}$, means that $f_g + f_c + f_B = 0$. Because $(f_c)_\lambda + (f_B)_\lambda = 0$, the geometry of the dipole field requires that $(f_c)_r = 2(f_B)_r = 2/3(-f_g)$. a , Central body; b , magnetic dipole field line.

In a dipole field $B_r = -(2a/r^3) \sin \lambda$, $B_\lambda = (a/r^3) \cos \lambda$, and so from equations (1)–(4) (for $\lambda \neq 0$)

$$f_c = 2aI/r^3$$

and

$$f_g = [f_c + (Ia/r^3)] \cos \lambda$$

showing that: $(f_c)_r = 2(f_B)_r = (2/3) |f_g|$. Thus the gravitational force is compensated to 2/3 by the centrifugal force, and to 1/3 by the electromagnetic force. The factor 2/3 is given by the geometry of a dipole field.

If condensation of grains (planetesimals) takes place from a partially corotating plasma, and the resulting grains are so large that the electromagnetic forces become small compared to f_c and f_g , then they will move in Kepler orbits. As the centrifugal force does not fully compensate the gravitation, the condensed grains will move in ellipses with eccentricity, $e = 1/3$ (refs 1–4). If a large number of grains have condensed in the neighbourhood of the central body and they collide with one another, the eccentricities of their orbits will diminish, so that eventually they will all move in more circular orbits, with a semimajor axis with a length which is 2/3 the distance to the point where the condensation occurred.

There are reasons to believe that condensation from a partially corotating plasma was a basic process in the formation of the Solar System. In fact, the structure of the Saturnian ring, and of the asteroid belt can be understood in this way^{1–3,11}. The factor 2/3 occurs in two places in the Saturnian ring system, and in two places in the asteroid belt. In the latter case the usual (n, a) diagram of asteroids has been used, giving the number density, n , of asteroids as a function of their semimajor axes, a .

Fig. 2 The smoothed (m, a) diagram. The curve has been smoothed with the weight function 1:3:5:3:1. Mass distribution in unit of gram within a radial distance interval of $\Delta a = 0.01$ AU. In order to emphasise the log scale, high density regions are darkened. The same diagram diminished by a factor 2/3 and turned upside down is shown above, in order to demonstrate the 'shadow' effect which produces the inner cutoff of the asteroidal belt. Similarly Jupiter's 'shadow', which generates the outer cutoff, is shown. Kirkwood gaps from Jupiter resonances are arrowed.

The diagram (n, a) only gives an approximate picture of the mass distribution in the asteroid belt. We have now, however, calculated an (m, a) diagram, giving the mass distribution. We have assumed that all asteroids have the same albedo and density, so that we can put their mass proportional to $(\text{brightness})^{3/2}$ (Fig. 2).

The (m, a) diagram shows the Kirkwood gaps, especially at 1/2 and 1/3, somewhat more clearly than the usual (n, a) diagram.

The limits of the main belt at $a = 2.15$ and 3.49 are also sharper (especially because a large number of asteroids below $a = 2.15$ have a negligible mass).

In order to study the effect of the fall-down ratio, 2/3, the (m, a) diagram, diminished by a factor 2/3, is shown reversed in the upper part of Fig. 2.

The diagram shows that the whole main belt is located below 2/3 of Jupiter's orbit, which means that the main belt asteroids may have derived from condensation which took place inside Jupiter's orbit down to $a = 3.49$. At this limit plasma would have condensed directly on already existing asteroids (or asteroidal grains), which therefore produced a 'shadow' at 2/3 this distance. As the diagram shows, there is a marked drop in mass density at $2/3 \times 3.49 = 2.32$. Above the 1:2 Kirkwood gap however, the mass density does not seem to be large enough to make the plasma density drop to zero. That does not occur until the 'shadow' of the bulk of asteroids below 3.20 appears at 2.13 (that is, $2/3 \times 3.20$).

There is no other known way to explain the upper and lower limits of the main belt.

The only asteroids outside the main belt which are massive enough to appear in the diagram are the Hildas, at $a = 3.95$ AU. As 5.9 AU ($3/2 \times 3.95$) exceeds Jupiter's distance from the Sun ($= 5.2$) they must have condensed outside Jupiter's orbit. When falling down in ellipses with $e = 1/3$ they avoided capture (or dispersal) by Jupiter because they were commensurable with Jupiter's orbit period to a degree of 2/3 that kept them from coming close to Jupiter. (Compare the Neptune–Pluto resonance and similar cases¹²).

The 2/3 ratio is found in three places in the asteroid (m, a) plot (Fig. 2). In fact, the observed ratios agree with the theoretical value to within 1%. Including the two occurrences in the Saturnian ring system there are five cases which confirm that the condensation from a plasma in partial corotation was an important process in the formation of the Solar System.

The mass distribution of the asteroids is not altogether explained by the resonances and the 2/3 fall-down. For example, there is a very strong peak at 2.75 which includes Ceres and Pallas, and a secondary peak at 2.36 which includes Vesta. These may result from a later evolution which concentrates mass through a process which eventually leads to the formation of planets.

A Lagrangian community?

It seems that it may be economically feasible, within the limits of the technology of this decade, to establish at one of the Lagrange libration points of the Earth-Moon system (called here L_5) a habitat capable of supporting and maintaining some 10,000 people. Projections indicate that this habitat, using free solar energy and the rich mineral resources of the lunar surface, could construct a still larger habitat, in a progression leading, possibly within 30 yr from now, to communities of from 10^6 to 10^7 people. These communities could be as comfortable as the most desirable parts of the Earth, with natural sunshine, controlled weather, normal air, apparent gravity and complete freedom from pollution. Replication of these communities could lead to the exponential growth of new land area, with a growth rate more rapid than that of the total human population.

Fig. 1 A graph, technically realisable in my opinion, showing that most industry could be removed from the biosphere of the Earth within a century. The graph is based on a "worst-case" assumption: no reduction of the population growth rate either on earth or in the space communities. P_E is the population on earth, P_S the population in space, A_S/A_E the ratio of land area in space (all usable) to the total land area of Earth. Changes within wide limits in the assumed input numbers do not affect reaching a solution stable in P_E and P_S/A_S . The final stable value of P_E (1.2×10^9 people) is equivalent to the 1910 value. —, P_E ; ---, P_S ; ·····, P_S/A_S ; ---, A_S/A_E .

A technically possible time-development is shown in Fig. 1, not as a prediction but as an illustration of the power of the technique.

Economic feasibility is defined here as the achievement of an overall cost less than or equal to that of the Apollo project. A reduction in the design size of the first habitat, with a corresponding reduction in the size of its population, would result in some further reduction in the estimates.

The solutions to several problems were necessary in order to achieve this feasibility:

- (a) Geometry: A physical arrangement has been found which would allow the use of natural sunlight for industry, farming and the maintenance of an attractive, earthlike environment with normal day/night and seasonal cycles.
 (b) Transport from the earth to L_5 : A reconfiguration of hardware already under development for the space-shuttle (to be operational by 1980) seems adequate to transport the necessary minimum of materials from earth.
 (c) Water: The combination, at L_5 , of hydrogen from the earth with oxygen from the abundant oxides of the lunar surface effects an important saving of a factor 9 in the mass of material needed from earth per unit mass of water at L_5 .
 (d) Materials: Obtaining nearly all the mass of the habitat from the moon appears essential for economy. Two alternative designs have been studied for the acceleration of lunar materials to the 2.4 km s^{-1} escape velocity of the moon. Both designs depend on the vacuum environment of the moon. Neither is conventional, but the technology of the present decade would suffice for either.

The ultimate benefits of this new possibility depend on the production of successively larger communities by a workforce which is housed, fed and maintained within the communities rather than on earth, and so to the eventual achievement by the communities of the ability to sustain their own growth by the construction of new lands and production facilities from lunar and asteroidal material.

These studies have been discussed in lectures at a number of universities during the past 18 months. Knowledge of the work has therefore spread, additional people have joined the effort, and recent progress has been rapid. On May 10, 1974, the first public meeting on this topic was held at Princeton University.

Detailed information on these studies will be found in forthcoming publications in *Physics Today* and in *Icarus*.

Intensity of the near infrared OH airglow

THE OH airglow was studied from the balloon-borne telescope Thisbe on three flights launched in 1971 and 1972 from the NCAR balloon flight station, Palestine, Texas (32°N , 95°W). The principal goal of these flights has been the measurement of the zodiacal light in the near infrared¹ with the airglow as a troublesome foreground contribution which had to be determined carefully.

The measurements have been performed from a float altitude of 32 km at wavelengths $\lambda = 0.82$, 2.1, and $2.4 \mu\text{m}$ with half power bandwidths $\Delta\lambda = 0.023$, 0.1 and $0.1 \mu\text{m}$ respectively. For the shorter wavelengths a straightforward photometer with a multiplier as detector has been used. The larger wavelengths were measured by a dry ice cooled PbS-photometer. The field of view of both photometers was 2° in diameter. The $0.82 \mu\text{m}$ photometer was calibrated by observations of 33 stars. The PbS-photometer was calibrated before the flight by a 240 K blackbody and during the flight by the star $\alpha\text{-Ori}$

$$\begin{aligned} (I_{2.1 \mu\text{m}} &= 1.9 \times 10^{-12} \text{ W cm}^{-2} \mu\text{m}^{-1}; \\ I_{2.4 \mu\text{m}} &= 1.3 \times 10^{-12} \text{ W cm}^{-2} \mu\text{m}^{-1}). \end{aligned}$$

The airglow intensity was determined from several elevation scans. As an example Fig. 1 shows the result of an elevation scan at $\lambda = 2.1 \mu\text{m}$.

A van Rhijn curve for an emission altitude of 92 km was fitted to the data. The resulting zenith intensities at all measured wavelengths are listed in Table 1.

Table 1 Zenith intensities of the OH airglow ($\text{W cm}^{-2} \text{sr}^{-1} \mu\text{m}^{-1}$)

Date	Time (CST)	λ (μm)	$\Delta\lambda$ (μm)	Intensity
May 13, 1972	23:00	0.82	0.023	$(2.5 \pm 0.4) \times 10^{-10}$
November 1, 1971	2:40	2.1	0.1	$(1.6 \pm 0.5) \times 10^{-9}$
October 24, 1972	2:00	2.1	0.1	$(1.6 \pm 0.3) \times 10^{-9}$
October 24, 1972	5:00	2.4	0.1	$< 6 \times 10^{-11}$

Fig. 1 OH airglow intensity at $2.1 \mu\text{m}$ determined from an elevation scan. A van Rhijn curve for an emission altitude of 92 km is fitted to the data. Notice the patchy structure at 65° zenith angle. $\lambda = 2.1 \mu\text{m}$; $\Delta\lambda = 0.1 \mu\text{m}$.

For comparison the results of other investigators are given. Sternberg and Ingham² found an average intensity of $2.9 \times 10^{-10} \text{W cm}^{-2} \text{sr}^{-1} \mu\text{m}^{-1}$ at $\lambda = 0.82 \mu\text{m}$. At $\lambda = 2.1 \mu\text{m}$ Noxon *et al.*³ determined an intensity of 1×10^{-8} and Moros⁴ an intensity of $5 \times 10^{-10} \text{W cm}^{-2} \text{sr}^{-1} \mu\text{m}^{-1}$. Peterson and Kieffaber⁵ determined at $\lambda = 2.2 \mu\text{m}$ ($\Delta\lambda = 0.54 \mu\text{m}$) an airglow intensity of $3.2 \times 10^{-9} \text{W cm}^{-2} \text{sr}^{-1} \mu\text{m}^{-1}$ from a broadband measurement. The differences of the results may be

Fig. 2 Simultaneous scans from the ecliptic plane ($\beta = 0$) to the north celestial pole (5,000 Å above, 8,200 Å below). Visual magnitude of the star δ Leo (A 4 V) is 2.56 mag. The signal registered at 8,200 Å is dominated by strong variations of the OH-airglow, at 5,000 Å the airglow contribution is much smaller.

explained by the local and temporal variations of the airglow intensity. At $\lambda = 2.4 \mu\text{m}$ Moros⁴ found an upper limit of $< 2 \times 10^{-10}$ and Noxon and Vallance Jones⁶ an upper limit $< 10^{-9} \text{W cm}^{-2} \text{sr}^{-1} \mu\text{m}^{-1}$. Our measurements indicate that at $2.4 \mu\text{m}$ the airglow intensity is at least three times smaller than previously known.

The patchy structure of the airglow was detected at 0.82 and $2.1 \mu\text{m}$ (see Figs 2 and 1). The patches have diameters of about 10° to 20° corresponding to 20 to 40 km in linear size. They differ from the average intensity up to 20%. Patches were also found at $0.8 \mu\text{m}$ by Peterson⁷ and at $2.2 \mu\text{m}$ by Peterson and Kieffaber⁵ using ground based measurements.

Our results have confirmed the existence of a theoretically predicted gap in the OH airglow emission at $\lambda = 2.4 \mu\text{m}$, which is also indicated in spectroscopic work^{8,9}. So surface photometry of extended celestial sources as the zodiacal light and the Milky Way is possible within this $\sim 0.3 \mu\text{m}$ wide gap from balloon altitudes. Because of the large intensity and irregularities of the OH airglow at shorter wavelengths serious problems arise in subtracting the airglow foreground from the night sky radiation.

We thank Dr. H. Elsässer, C. Thum, K. Haussecker, and H. Schütz, for help, and the National Center for Atmospheric Research (NCAR), Palestine, Texas, for balloon launch and flight assistance. The project was supported by the Bundesministerium für Bildung und Wissenschaft.

Positron annihilation in EAS and ball lightning

CRAWFORD¹ has suggested that the bursts of γ -ray energy that correspond to positron annihilation at rest (0.511 MeV), which have been observed by Ashby and Whitehead², may be caused by extensive air showers (EAS) of primary energy $E_0 \approx 10^{16}$ eV. We present two major objections to that hypothesis.

First, we shall discuss the duration of the four γ -ray bursts which were detected. Ashby and Whitehead² report an upper limit of about 10 s for the duration of three events, and the fourth lasted about 3 s. Those two values corresponded to two different time constants of the recording device: 25 s and 1 s, respectively. The lower limit for the duration can be derived from the time resolution of the NaI(Tl) γ -ray detector which was used, about 0.25 μs . A lower limit of $3.7 \times 10^3 \times 2.5 \times 10^{-7}$, ≈ 9 ms, can be given for the duration of the four events, as the event with the lower flux corresponds to 3.7×10^3 distinct counts. On the other hand, the delays in the distribution of the various EAS components must be considered. The electronic component, at distances relatively close to the shower axis, shows time-spreads of less than a few tens of ns (ref. 3), where-

as the delays observed for muons are of the order of several hundreds of ns. Slow neutrons which are delayed by no more than several μ s are the most delayed particles detected⁴. Finally, considering that positron annihilation times which correspond to the slower annihilation modes are of the order $\approx 10^{-7}$ s (ref. 5), it is hard to understand a γ -ray emission of 0.511 MeV from an EAS of such a long duration (≈ 1 ms.)

The number of photons which it is claimed were created seems rather high. Consider the energy deposited by the shower particles in the first radiation length in the ground, inside a disk of radius $R = 2$ m. The energy dissipated by an EAS is represented by the track length integral (ref. 6). In the lower atmosphere, after the maximum longitudinal development, the integral is represented by

$$E_{\text{diss}} = \epsilon_0 N_{s,l} \int_{t_{\text{max}}}^{\infty} \exp [0.18 (t_{s,l} - t)] dt$$

where ϵ_0 is the 'critical energy' and its actual value in air is approximately 84 MeV. For a shower generated by a particle of energy $E_0 = 10^{16}$ eV, we assume $t_{\text{max}} = 18.6$, $t_{s,l} = 28.4$, and $t_c = 74.4$, considering t_c when the EAS 'age parameter', s , is 2. The integral over the portion of the curve of the longitudinal development which is extrapolated below sea level (s.l.) to t_c gives $E_{\text{diss}}/N_{s,l} = 465$ MeV, and the value of the same quantity for the first radiation length in the ground turns out to be 71 MeV. The quantity $N_{s,l}$ represents the size, at sea level, of a shower initiated by a particle of energy $E_0 = 10^{16}$ eV. On average it is 3×10^6 (ref. 7). Furthermore, we have to consider the lateral distribution of these particles to estimate the energy dissipated within the 2 m disk. Near the shower axis the density of particles, D , is well represented by the expression

$$D = N_{s,l}/500r$$

so that the number of particles inside the disk turns out to be approximately 2.5% of the total number. Thus, the energy dissipated in the first radiation length in the ground and in the region with $r = 2$ m will be

$$E_{\text{diss}} (r \leq 2 \text{ m}) = 2.5 \times 10^{-2} \times 3 \times 10^6 \times 71 \times 10^6 = 5.3 \times 10^{12} \text{ eV}$$

Assuming¹ that 5.5% of E_{diss} will be converted into photons with an energy of 0.511 MeV, a total of $5.7 \times 10^8 \gamma$ will be emitted. The detector has an estimated geometric factor of 3.6×10^{-4} so that about 210 photons are finally seen. That is an order of magnitude smaller than the lower value of γ detected in the four observed events.

To increase this value, a higher primary energy, E_0 , of more than 10^{17} eV is required. In this case, however, the flux of cosmic rays, Φ , is $2 \times 10^{-10} \text{ m}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (ref. 8). Thus, with a sensitive area, A of 10 m^2 , and a solid angle of acceptance, Ω of 3.1 sr, and assuming a running time, T , of 1.3×10^7 s, the number of events which can be expected is

$$n = \Phi A \Omega T = 0.08$$

In fact, four were observed under the same conditions.

Therefore, it seems to us that the hypothesis of γ -ray production from positrons of an EAS annihilating at rest has to be ruled out.

We thank Professor M. Galli and Dr G. Cavallo for discussions.

Observations from Skylab of mesoscale turbulence in ocean currents

PHOTOGRAPHS and visual observations made by astronauts aboard Skylab have revealed remarkable eddies embedded in warm-water currents flowing poleward from equatorial oceans. These visual displays of mesoscale turbulence provide us with (1) a concept of the size and shape of such features, (2) an opportunity to examine the places of origin, (3) a feel for the rate at which they coalesce, and grow downstream, and (4) the opportunity to ascertain their significance in the thermal energy regime of the oceans.

I identified the eddies from photographs taken aboard Skylab 2 (May-June 73) over the northwest Caribbean Sea. Lying in the current, on the left-hand side, the vortices varied in diameter from 3-20 nautical miles. The associated atmospheric manifestations indicated cool surface water temperatures in the eddies, and down-current boundaries with waters warmer than those of the open current. There were (1) a smoother sea surface within the eddies than out-

Fig. 1 Photograph (NASA No. SL2-10-072), taken vertically from the colour band of the Itek, 6-lens, 70 mm camera, with a 6 inch focal length lens, aboard the Skylab Space Station in June, 1973. The centre point of the area photographed is about $19^\circ \text{ N } 85^\circ \text{ W}$ and the ocean area covered is 60×60 nautical miles ($3,600 \text{ nm}^2$). Winds were from the southeast at 15-20 knots; the white, small "puff-ball" cumulus being aligned with the wind. The Yucatan Current flows north (top of picture) at speeds of 1-1.5 knots in this location, during this month of the year. The sea surface expression of the eddies are the oval, smoother, apparently indented features, and the atmospheric manifestations are the (1) disruption of the cloud streets, and (2) alignment of towering cumulus (to 35,000 feet) on the downstream edge of the eddies.

side, (2) a disruption of the wind-driven Langmuir circulation in both the sea surface and the overlying atmosphere, (3) towering crescent-shaped cumulus over the down current boundary, and (4) clear skies over the eddies (Fig. 1).

Although turbulent eddies of this nature and size have not been well documented, Spilhaus¹ noted eddies 30 miles in diameter during tests of the mechanical bathythermograph in the Gulf Stream. He pointed out that such scales

Fig. 2 Photograph (NASA No. SL4-137-3608) taken with a handheld Hasselblad, 70 mm camera, 100 mm focal length, from the Skylab Space Station, December, 1973, of the Southwest Atlantic Ocean near the coast of Argentina; Puerto Deseado was visible through the cumulus, middle left in the photograph. The centre point of the ocean covered by this photo is about $48^{\circ} 30' S$ $63^{\circ} W$ and the area is 210×210 nm ($44,400$ nm²). During this time of the year, upwelling takes place adjacent to the coast (beneath the huge, white cumulus caught in this photo) whereas about 100 miles offshore, a flow of warm water (50 – $55^{\circ} F$) moves south. Farther offshore, the cold (44 – $45^{\circ} F$) Falkland Current intrudes northward to the latitude of Montevideo ($35^{\circ} S$). On the day this photo was taken, the warm, nearshore counter-current was seen to be defined by the "puff-ball" cloud streets in the overlying marine atmosphere, into which intruded the clear skies overlying the cold eddies. The strong interaction between the countercurrent and the Falkland Current was manifested on this day by the strong blooms of phytoplankton; the light-coloured waters visible beneath the cumulus clouds.

implied a high rate of shear and were of the order of magnitude estimated by Rossby on the basis of a $10^{-3} s^{-1}$ shear. Further notations of "cold-water eddies"^{2,3} have been of eddies on current boundaries; formed from meanders, and are thus of a differing origin. That such turbulence has gone without much documentation is probably because of the (1) difficulty of detecting them by conventional oceanographic techniques, (2) a lack of knowledge of the sizes, persistence, and continuity of such features, and (3) the lack of photographs from orbital platforms which enhance the ocean/atmosphere manifestations of the eddies.

Because of their distinctive features, it was believed that the eddies could be examined visually by the three astronauts (Lt Col. Gerald Carr, Lt Col. William Pogue, and Dr Edward Gibson) aboard Skylab 4. Consequently, a request was made for visual observations by the astronauts early on the morning of 6 December 1973, as the spacecraft crossed the Caribbean Sea.

The characteristic clouds were indeed seen by all three astronauts, but the Sun angle was too low to enable examination of the ocean surface in the Sun's reflection. The next day, during a parallel orbital pass, but 180 miles to

the east, television on board scanned the Caribbean Sea, and the crescent-shaped clouds associated with the eddies were monitored to the coast of Columbia. Distinct eddies had also been caught by the camera during Skylab 3 (August–September), just south of those interpreted from Skylab 2. Similar cloud arrangements were also photographed south of Western Samoa, and the Gulf Stream east of Hatteras. The evidence was convincing, therefore, that turbulent vortices were constantly embedded within the main stream of warm ocean currents, and that they could be visually monitored from space.

Subsequently, observations from Skylab 4 confirmed that the turbulent features were in four other ocean areas (Coral Sea, North and South Equatorial Pacific, and western south Atlantic). Furthermore, eddies with similar surface manifestations, but not the towering cumulus, were observed east of New Zealand and in the Pacific north of Hawaii. These latter observations were confirmation that turbulent vortices of such magnitude are present wherever conditions are suitable, regardless of water temperature, and that eddies in warm currents are simply easier to see (and photograph) because of the atmospheric manifestations (Fig. 2).

We still had no definitive data, however, from the Caribbean Sea. Consequently, on January 24, 1974, personnel from the Navy's Weather Reconnaissance Squadron Four flew over the northwest Caribbean Sea, planting air expendable bathythermographs (AXBTs) along two lines, each about 200 miles long. An AXBT was dropped every ten nautical miles on both tracks. Heading south, the aircraft followed a flight line directly over waters on the left side of the core of the Caribbean Current. The second line was 60 miles to the east over the axis of the current.

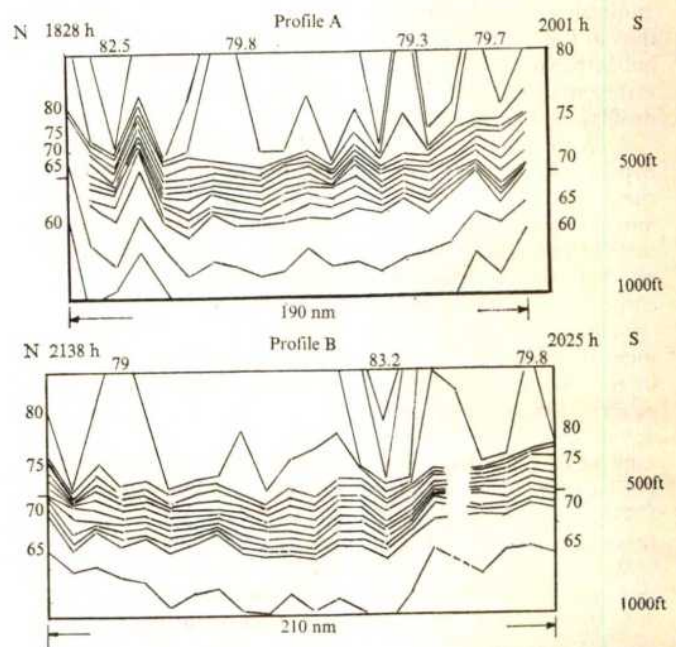

Fig. 3 North and south profiles of the vertical distribution of water temperature in the Yucatan Current on January 24, 1974. Air Expendable Bathythermographs (AXB) were dropped every 10 nm from a weather reconnaissance aircraft of the US Navy's VW-4 Squadron, Jacksonville, Florida. Profile A was flown first, beginning at 1828 GMT from $20^{\circ} 30' N$ $86^{\circ} 40' W$, the aircraft proceeding south-east for 190 nm. Skylab orbit overhead along the aircraft's track from 1831–1831:35 GMT. Profile B was started at 2138 GMT from $18^{\circ} N$ $83^{\circ} 40' W$, the aircraft proceeding north for 210 nm. The upward "doming" of cold water in the cyclonic eddies was encountered frequently along the first flight line, as expected in that the waters were well to the left of the current axis. (Note that the isotherm interval in the illustration is $1^{\circ} F$ to 70° ; then $5^{\circ} F$ to 60° . The vertical temperature gradient is nearly constant to depths of 1,000 feet.)

The temperature profiles (Fig. 3) indicated cyclonic eddies along the length of the flight line. The most dramatic modification of the ocean's thermal structure was in the vertical displacement of the deep-lying thermocline. Along the core of the current, the displacements of the isotherms were more subdued than to the west. It became clear from these data that the turbulent features were constantly forming and growing in the strongly flowing current.

The two most likely sources for the eddies are (1) seafloor irregularities projecting into the surface layers, and (2) shear stresses along discontinuities in the current.

There are reefs on the Honduras Shelf over which the Yucatan Current flows before reaching the waters in which the eddies were photographed first. That the eddies show no organised shedding, such as Von Kármán or Kelvin-Helmholtz vortices, could simply be the result of multiple points of origin, thus masking organised structure. But, similar eddies and their uniquely associated clouds were observed from the Skylab 4 spacecraft in the Brazil Current (Fig. 2), the equatorial Pacific, the Coral Sea, the southern Caribbean Sea, and the Gulf Stream. In none of these areas do seafloor features jut into the surface currents. Such an origin does not seem to account, therefore, for the observed eddies.

The density discontinuity of the thermocline is well formed in the Yucatan Current⁴. A shear along this horizontal surface would result in turbulence, probably in the form of elongated "rols", however. A rotation around a near-vertical axis would be precluded⁵.

Probably, shear stresses across the velocity profile initiate the turbulence (as noted by Spilhaus¹, and calculated by Rossby) rather than the other causes considered. Wherever the eddies have been observed, the current velocity diminishes sharply over distances of only a few miles from that in the current core. That the eddy shape is not circular indicates that the velocity shear takes place along a sloping rather than a vertical plane which is consistent with velocity profiles in ocean currents.

Such turbulence has been studied in the laboratory⁶, and Brown and Roshko⁷ have examined it in detail and theorised on the development and growth of eddies as they move downstream. Should the Yucatan-type eddies be of this origin, then we must expect them to decrease in number and increase in size in a down-current direction; conserving vorticity through the sequence.

Some details from the ocean may come from an experiment planned for the Coral Sea in March 1974, by scientists in the Royal Australian, New Zealand and United States navies. The earliest opportunity to check the concept of down-current eddy amalgamation, which in the ocean must take place over distances of 1,000 miles, will be during the joint orbital manned mission of the United States and the USSR, in July of 1975. By mid-1975, a better definition of these unique ocean features may be possible.

We thank Lt Col. Gerald Carr, Lt Col. William Pogue, and Dr Edward Gibson, the Visual Observation Team, Johnson Space Center, Houston, and Weather Reconnaissance Squadron Four, Jacksonville Naval Air Station, for help.

Lipid chemistry of eastern Mediterranean surface layers

It has been well established that organic surface films exist in most of the world's major oceans¹⁻⁹. They consist mainly of natural lipid material, with generally much smaller, though variable, amounts of petroleum hydrocarbons. Because the Mediterranean Sea is a restricted area the input of petroleum hydrocarbon is more noticeable than in most oceanic areas, and the level of surface pollution is probably increasing there because the major outflow occurs below the surface in the Straits of Gibraltar.

On a recent cruise of RRS Discovery in the Eastern Mediterranean, heavy oil slicks were encountered south of Cyprus and off the coasts of Libya and Egypt. Large coherent lumps of tar (tarballs) were often present with these heavy slicks, and in many places the associated surface films covered more than 60% of the surface area. In addition, when windspeeds were less than 10 knots, films not associated with oil slicks covered fairly large areas (30-40% at times). In certain coastal areas these surface films were accompanied by oil/water emulsions.

The surface films, emulsions, tarballs and surface living plankton were sampled at certain stations well away from heavy oil slicks in the eastern Mediterranean (Fig. 1). Their lipid composition and the extent to which petroleum hydrocarbons are entering the lipids of organisms which are exposed to high levels of oil pollution have been studied (Table 1).

A more detailed treatment of the results and sampling techniques will be published elsewhere¹⁰, but it should be emphasised that great care was taken to remove surface oil from organisms before analysis. The results can be summarised as follows:

Tarballs: in areas which were not grossly polluted by heavy slicks the distribution of tarballs was estimated to be 0.7-10 mg m⁻².

Emulsions: large scale distributions of oil/water emulsions were found off the Libyan and Egyptian coasts, possibly resulting from the practice of washing oil tanker's storage tanks down with high pressure water and discharging the washings before entering port. We made no estimate of the total organics present in the emulsion form, but a 54-mesh net collection gave a distribution of 0.1-0.5 mg m⁻² near the coast, with much lower concentrations in areas away from the coast. The emulsions were composed of both natural product organics (< 15% total extract) and a complex mixture of pollutant hydrocarbons (> 75% total extract).

Surface film: the surface film samples gave a distribution of 40-230 mg of organics per m², giving an estimated film thickness of 0.0005-0.003 cm. These values are similar to the estimate¹¹ that the oil slick observed six days after the stranding of the Torrey Canyon, which measured 10 by 40 miles, would have had an average thickness of 0.003 cm. The films were composed of both natural product lipids (< 5% total extract), which would be expected to form normal monomolecular films^{2,4}, and the complex mixture of pollutant hydrocarbons (> 85% total extract), which would give rise to polymolecular films^{9,12}.

Zooplankton: samples of near-surface crustaceans, fish and mixed plankton contained large amounts of hydrocarbons in their lipids (17-33% of total lipid; the lipid content of the animals was 2-3% of the total wet weight). These hydrocarbons

† Windspeed < 4 knots.

were composed mainly of the complex mixture found in the emulsion and surface film samples, quite unlike the much simpler, natural product hydrocarbon composition normally found in unpolluted marine organisms¹⁹⁻²¹. In addition, natural product hydrocarbons are usually only minor components of zooplankton lipids (< 5% total lipid)^{22,23}.

These results confirm that the surface layers of the eastern Mediterranean are polluted with petroleum hydrocarbons in the form of surface films, slicks, oil/water emulsions and tarballs;

light penetration must all be considered among the long term physical effects of this pollution. The presence of high levels of non-natural product hydrocarbons in the lipids of the zooplankton samples is also a cause for concern. We suggest that either the zooplankton species examined do not have an effective metabolic mechanism for dealing with non-natural product hydrocarbons, or this mechanism has been overloaded by high levels of pollutants. It may well be that these zooplankton species can tolerate high levels of pollutant hydro-

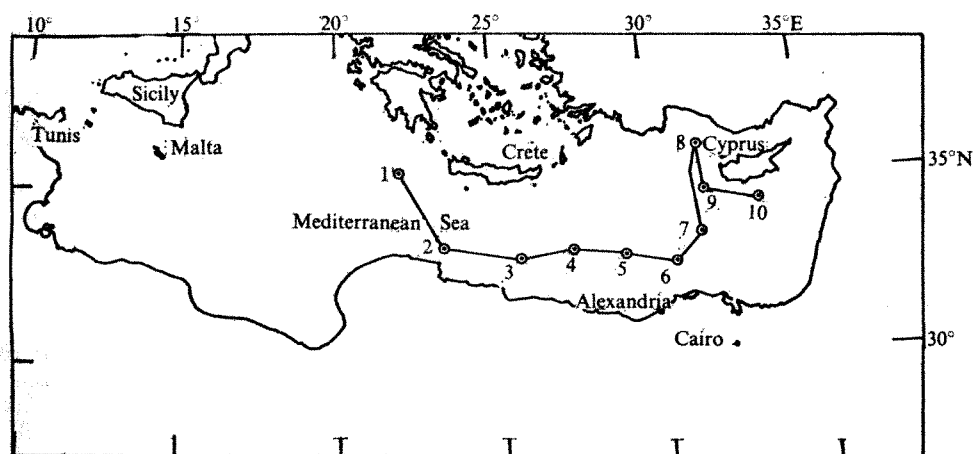

Fig. 1 Sample sites in the eastern Mediterranean. Numbers as in Table 1.

in many places the natural monomolecular surface films are swamped by polymolecular oil films. The combined natural and non-natural film material covers large areas of the surface of this region under calm conditions. The influence on interface properties such as evaporation, solid/liquid exchange, gas exchange between the atmosphere and sea, wave formation and

carbons in their lipids without being adversely affected but, nevertheless, the near-surface plankton do represent a stage at which these compounds can be introduced into the marine food web.

In view of the increase in oil tanker traffic in the Mediterranean which will result from the re-opening and proposed

enlarging of the Suez Canal, it seems likely that the situation can only become worse.

Archaeomagnetism and archaeoclimatic 'forecast'?

It has been suggested¹ that the semipermanent pattern of depressions of tropospheric pressure in the north polar regions may be associated with areas of high magnetic field intensity in Canada and Siberia. The physical reasons for the correlation are obscure, because contrary to earlier suggestions, field lines near the magnetic pole are not linked to the interior of the magneto tail². Nevertheless, the hypothesis, as an empirical principle, is of wide interest in that it would not only organise archaeoclimatic data but it would also form a basis for long term forecasting of general circulation changes.

I here test some aspects of the hypothesis by correlating archaeomagnetic and archaeoclimatic observations from various regions of the globe. Although there may be a tenuous correlation between them in some cases, the total pattern of archaeoclimatic regimes from central Europe to western America does not seem to follow the westward drift of the geomagnetic field pattern. I suggest that climatic regimes may be composed of a global component—related to variations of the solar constant—and of a possible westward drifting component.

First, if there is geomagnetic control of the pressure pattern in the troposphere^{1,3}, then a climatic response to long term variations of geomagnetic field intensity may be expected over the whole globe. Indeed, if the main dipole field weakens, as at present, there is reason to believe that cosmic ray particles would be more readily accessible to the atmosphere⁴. Because the geomagnetic dipole moment, M , declined to approximately

Fig. 1 *a*, World averaged dipole magnetic moment of the Earth for the past 9,000 yr (refs 5 and 6). Solid squares, averages with statistically significant number of samples. *b*, Damon's construction⁷ of deviations from the reference level (1890 AD) of long term averaged temperature. The construction is based on historical records and ocean cores.

half of its present value in the period 3000–5000 BC (Fig. 1*a*; refs 5 and 6), it may be expected that there was a major climatic response in the same period. Figure 1*b* shows a construction⁷ of deviations from the reference level (1890 AD) of long term averaged temperature according to Damon⁷. Although the actual value of ΔT is debatable⁷, it is important to note that the major climatic optimum of postglacial times—3000–5000 BC—seems to stand in anticorrelation with the intensity of the geomagnetic field. As the climate may be affected by many factors, including changes in the solar constant and in the oceanic circulation this single correlation cannot be construed as evidence in support of King's¹ hypothesis.

The hypothesis that the westward drift of the semipermanent depression of tropospheric pressure follows the westward drift of the geomagnetic field pattern, can be tested by considering local archaeomagnetic and archaeoclimatic data according to longitude (Fig. 2). Similar variations in the archaeomagnetic field intensity—in units of the present value, B_0 —in both central Europe and Arizona–Mexico (Figs 2*a* and *c*) can, according to Bucha⁸, be interpreted as resulting from the westward drift of the northern geomagnetic field pattern (there are two regions of stronger field, over both regions): that would account for the 500-yr phase difference between the two sets of data.

The qualitative climatic variations of Greenland—midway between Central Europe and Arizona–Mexico—can be represented in terms of $^{18}\text{O}/^{16}\text{O}$ isotopic ratio deviations obtained from ice cores (Fig. 2*b*; ref. 9). In order to trace the possible westward drift of clear-cut geomagnetic and climatic events, I have identified on Fig. 2*a* some climatic episodes in central Europe. The occurrence of a cold period in Poland and Czechoslovakia between 800 BC, and 200 BC, is well established^{10,11}, although a later warm period may have been interrupted by minor cold episodes. The empirical association of this pre-Christian cold episode with the peak in geomagnetic field intensity at 500 BC, is compatible with the hypothesis that a semipermanent low may have been located in the north of central Europe at that time. The consistency of this empirical association, as well as the westward drift hypothesis, can be

tested. A cold episode occurred in Greenland at about 100–400 BC, some 200–300 yr after that in central Europe (Fig. 2b). (Although there are difficulties in the chronology of ice-core analysis, ref. 9 shows that the data are consistent with historical records in the short term, and with varve and ocean core chronology in the long term). On the other hand there is no consistent association between climatic and magnetic episodes in post-Christian central Europe between their westward drift to Greenland (Figs 2a and b). Nevertheless, if the sequence of climatic and geomagnetic associations during the cold episode in the first millennium BC is taken seriously, King's hypothesis would lead to the conclusion that such an episode would have drifted to western North America by about 200 AD, in accordance with the geomagnetic field drift (Fig. 2). The climatic record of the White Mountains of California has been derived from tree rings of the bristlecone pine (Fig. 2d; ref. 12). It can be seen that a cold episode did occur in the

Fig. 2 a, Archaeomagnetic intensity, relative to the present value B_0 , for central Europe, 15° E (ref. 8). The indicated warm period, 200 BC–1400 AD may be interrupted by minor cold epochs. The Little Ice Age of circa 1600 AD is omitted. b, Archaeoclimatic data for Greenland (40° W) based on percentage deviation of $^{18}\text{O}/^{16}\text{O}$ isotopic ratio in ice cores⁹. Longer term averaged data before 200 AD taken from Fig. 4 of ref. 9. The continuous curve after 200 AD is drawn through the centroid of shorter term averaged data from Fig. 2 of ref. 9. c, Archaeomagnetic intensity, relative to the present value B_0 , for Arizona-Mexico, 105° W (ref. 8). d, Climatic record of the White Mountains of California (120° W) as indicated by the widths of bristlecone pine tree rings¹². In each case the horizontal dashed line is the mean.

first millenium AD; it was however, considerably later than 200 AD. Consequently, the archaeomagnetic and archaeoclimatic evidence available at present indicates only a tenuous correlation, at best.

In examining and interpreting the correlation of data discussed here, account must be taken of the preliminary nature of Bucha's⁸ interpretation of changes in field intensity observed for central Europe and western America. He suggested that they resulted from the westward drifting non-dipole field; even though the estimated rate of westward drift is in agreement with the better established nondipole drift of later epochs. As the data in Fig. 2 seem to be the only archaeoclimatic and archaeomagnetic data available at present for the same locations during the same epochs, I present them not only to indicate the present evidence for or against King's hypothesis, but also to emphasise the need for simultaneous and local data of both types. Evidence presented in support of the proposed hypothesis, including the original analysis¹, is based on isolated correlations; therefore, it seems that a systematic test, such as the determination of the westward drift of geomagnetic and climatic patterns, would be crucial in determining whether the hypothesis would be useful as an empirical principle for organising archaeoclimatic data. On the other hand, the organisation of climatic records according to longitude, such as in Figs 2a–d, does serve to distinguish global from local climatic episodes. Despite possible correlations with the geomagnetic field pattern, it is likely that the cold episodes at about 500 BC, and at about 1600 AD, are global in nature.

Interaction of coherent electromagnetic waves with relativistic electrons in a medium

A MECHANISM is proposed here for producing coherent photons by the interaction in a medium of relativistic electrons (moving with velocity greater than the electromagnetic phase velocity in the medium) with coherent electromagnetic waves incident in the opposite direction. A new effect of potential use is exhibited; it is a consequence of two distinct physical phenomena acting synergistically to result in double-Doppler-shifted coherent waves contained within a Mach cone. Its applications include production of narrow band radiation at higher frequencies and wave numbers than are at present available from

lasers, which has implications for holography and for improved pumping efficiency and production of narrow band submillimetre waves from microwaves, which has significance for communications.

When a material body moves in a medium with a speed greater than that of the waves it produces in the medium, the energy accumulated in these waves cannot get ahead of the moving body, resulting in a wave with a sharp discontinuity on the Mach cone. In the field of hydrodynamics, the basic phenomenon is a shock wave. For a charged particle moving at a constant speed in a medium with index of refraction greater than unity, and with particle speed exceeding the phase velocity of light in the medium, the radiated wavelets emitted by the medium under the action of the field of the particle at different points of its path interfere constructively at the Mach angle, resulting in Čerenkov radiation. The radiation vanishes outside the Mach cone and peaks sharply near the edge of the cone.

A similar discontinuity and attendant enhancement of radiation near the edge of the Mach cone ought to occur because of the effect, on suitable media and at appropriate particle velocities, of the scattered-radiation field of a charged particle accelerated by a coherent electromagnetic field, but at the double-Doppler-shifted frequency that characterises Thomson (Compton) backscattering of laser light from energetic electrons.

Conversion of optical photons into ones of higher frequency in a vacuum by Compton backscattering of laser photons from energetic electrons has been observed^{1,2} in the laboratory. This vacuum effect^{1,2} does not fully exploit the coherent-wave nature of the laser source, and the original discussions³⁻⁵ of this effect did not consider the coherence properties of the incident radiation.

We extend these considerations by taking into account the coherence of the field driving the charged particle and by examining the laser-stimulated wave emission under conditions where the velocity of the scattered-field source exceeds that of field propagation in the medium. The properties of the scattered wave in these conditions are essentially different from Compton-backscattered waves in vacuum. We also discuss possible constructive interference from many-electron effects. The calculation is classical since the basic effect does not depend essentially on the quantum nature of light. Quantum corrections are small for most parametric ranges of interest.

We consider a relativistic electron moving with speed u , along the positive z axis, in an infinite medium of unit magnetic permeability. The electric field of the untruncated plane wave incident in the opposite direction (head-on collision) is

$$E_0(\mathbf{x}, t) = E_0 \sin(\omega_0 t + k_0 z), \quad (1)$$

where $k_0 c = \omega_0 n$, c is the speed of light in vacuum and n is the index of refraction at the incident laser frequency. All quantities and results are in the rest frame of the dielectric. We consider first the case of a slightly dispersive medium, so that the dielectric constant ϵ at the scattered frequency can be reasonably approximated by a constant, though we include the possibility $\epsilon = n^2$, and take $\beta^2 \epsilon > 1$, where $\beta = u/c$. The scattered double-Doppler-shifted field (in cylindrical coordinates ρ, z) is, to order E_0 ,

$$E(\rho, z, t) = 2(r_e/\omega_0)(\gamma/\gamma_0)E_0 \frac{\partial}{\partial t} \left\{ (\tau) \Theta(\gamma u \tau - \theta) \right. \\ \left. \times \cos[\Omega(\gamma^2 \tau - z/u)] \frac{\cos[\alpha(\gamma^2 u^2 \tau^2 - \rho^2)^{1/2}]}{(\gamma^2 u^2 \tau^2 - \rho^2)^{1/2}} \right\} \quad (2)$$

where r_e is the classical electron radius, $\gamma_0 = (1 - \beta^2)^{-1/2}$, $\gamma = (\beta^2 \epsilon - 1)^{-1/2}$, $\theta(x) = 1$ for $x > 0$ and $\theta(x) = 0$ for $x < 0$, $\tau = t - (z/u)$, $\Omega = \omega_0 + k_0 u$, and $\alpha = \gamma \Omega \epsilon$.

The component K_z of the wave number for propagation of the scattered wave in the z direction is

$$K_z = (\Omega_z/u)(1 + \gamma^{-2}) \quad (3a)$$

where

$$\Omega_z = \gamma^2 \Omega = [\omega_0(1 + n\beta)/(\beta^2 \epsilon - 1)] \quad (3b)$$

is the corresponding frequency of propagation; that is, this component of the wave has a phase velocity v_z dictated in part

by the electron velocity,

$$v_z = u(1 + \gamma^{-2})^{-1} = c/(\beta \epsilon) \quad (4)$$

Note that the maximum enhancement of the frequency, at least for the simple model considered here, occurs just above threshold for the effect. As β increases beyond threshold, for a constant ϵ , Ω_z decreases. This differs qualitatively from the vacuum effect, where the scattered frequency increases monotonically with β . The effect can therefore be optimised for certain parametric ranges by suitable adjustment of ϵ for a given medium, for example, by varying the density of a gas. Scattered coherent waves of 10^2 to 10^3 times incident infrared frequencies should be realisable in low-density gases with $0 < \epsilon(\Omega_z) - 1 \ll 1$.

The scattered field vanishes outside the Mach cone of half angle $\phi = \sin^{-1}(v_p/u)$, where $v_p = (c/\epsilon)^{1/2}$ is the phase velocity of electromagnetic disturbances in the medium; $v_z = v_p \sin \phi$. The intensity increases sharply as the conical edge is approached. The singularity in Equation (2) for the field on the cone is in reality smoothed out by the absorptive properties of a dispersive medium, as in the Čerenkov case, and by energy losses of the charged particle, which serve to place a lower limit on the parameter $Q = \gamma^2 u^2 \tau^2 - \rho^2$ that results in the singularity for $Q = 0$ when dispersion and these losses are not taken into account.

To estimate the field energy of the scattered double-Doppler-shifted wave, we keep only the dominant contribution to the expression (2) in the frequency range 10^{14} to 10^{18} rad s⁻¹ for ω_0 and take the energy loss in the medium into account phenomenologically. The ratio η of the energy scattered from a single electron to that of the portion of length L of the laser beam which overlaps the electron beam in the dielectric is then $\eta = (2\pi r_e^2/A)(L/L_1)(\gamma/\gamma_0)^2(\Omega_z/\omega_0)^2(\beta^2 \epsilon)^2(\Omega_z \tau_a)^2 \ln(R/2L_1)$, (5)

where R is the range of the electrons, L_1 is the distance over which the Mach cone builds up (the interaction length), A is the cross section of the laser beam and τ_a is a representative value of τ during the time T of interaction of a single electron with the incident wave in the medium. We assume the total lengths of the laser and electron beams to be larger than the dielectric thickness, which is readily achievable and renders independent of these lengths the ratio η and, for fixed electron beam density, the quantities η_{coh} and η_{incoh} given below. By definition, we then have $L \simeq L_1$, and geometry of the cone dictates $\tau_a \simeq T/3$. From equations (5) and (3b), η is proportional to γ^{10} , so that a change of $\beta^2 \epsilon$ from 1.2 to 1.05, for example, increases η by three orders of magnitude. We have, however, made no systematic effort to optimise the various relevant parameters such as dielectric constant, electron energy, or pulse time and total energy of either the electron or laser beam.

Expressions (2) and (5) apply to scattering from a single electron. The number N of electrons in the beam that act at a fixed time to produce the desired effect is given in terms of the total number N_0 of beam electrons by $N = N_0(d/L_e)$, where we assume the electrons to be uniformly distributed in a beam of length L_e and d is the thickness of the dielectric. Two limiting cases will be considered.

For electrons bunched in space-time so that the resulting phases $(\Omega_z t - K_z z)$ of the waves scattered from different electrons are all within, say, the same quadrant, these waves will add constructively. Because the electron and wave velocities are nearly equal, waves scattered from electrons bunched within $1/4$ wavelength λ of the scattered radiation will also be within $1/4$ period of one another. Such constructive interference from randomly distributed electrons may be realisable by using a thin dielectric film of thickness $\gtrsim \lambda/4$. The number N_c of electrons in the beam that can act coherently is then given by $N_c = N_0(\pi c/2 \Omega_z L_e)$. Additional enhancement may be obtainable by using a suitable array of periodically spaced thin films, by modulating the electron beam and by time phasing of the laser pulse. In adding coherently the contributions from different electrons, one should in principle fold in a factor for the spread in electron velocities. In practice, the phenomeno-

logical treatment referred to above takes this partly into account. For an interaction region larger than a wavelength, the total intensity of radiation from randomly distributed electrons will be the incoherent sum of the individual electron contributions. The ratio for coherent scattering from a beam of electrons interacting in a single thin dielectric, $d \approx \lambda/4$, is $\eta_{\text{coh}} = N^2 \epsilon \eta$. For $d \gg \lambda/4$, we get $\eta_{\text{incoh}} = N \eta$.

As a specific example, we consider an electron beam that delivers $N_0 = 10^{18}$ electrons in a 5×10^{-8} s pulse at an average energy of 5 MeV ($L_e \approx 1,500$ cm, $\gamma_0 \approx 10$), and a dielectric of thickness $d = 1$ mm, $R = 1$ cm and $\epsilon = 1.2$, so that $\gamma^2 \approx 5$ and $\Omega_e/\omega_0 \approx 10$. Taking an infrared laser (10^{14} Hz), for which $\Omega_e \tau_a \approx 6,000$ produces an ultraviolet incoherent scattered wave of relative intensity $\eta_{\text{incoh}} \approx 10^{-2}$. For a thin film of $d = \lambda/4 = 7.5 \times 10^{-6}$ cm, the coherent scattered wave is in the ultraviolet with $\eta_{\text{coh}} \approx 4 \times 10^{-5}$.

The portion of the electron beam that can contribute to the process will in general be limited by the time over which the essential dielectric and material properties of the medium are not destroyed by the laser or electron flux. Estimates for glass indicate no significant change in the electric susceptibility for the above laser and electron parameters. But for a 5-MeV electron beam with $N_0 > 10^{15}$, the physical state of the glass may alter before all the electrons have passed through.

The effect can also be used to generate coherent millimetre and submillimetre waves from intense coherent microwaves, such as from magnetrons, in slow wave or periodic structures (simulated dielectric media). In the case of such simulated dielectric media, where the effect we consider can actually take place in vacuum, the duration and intensity of the scattered radiation are not limited by either the dielectric or the material properties of a medium.

The discussion up to now has involved scattered radiation at energies below those at which atomic resonances occur, for which the assumption of slowly varying electric susceptibility is expected to be valid. The general nature of the physical mechanism underlying the effect we have discussed strongly suggests however that the qualitative features of the effect will persist in the region of anomalous dispersion corresponding to X-ray and γ -ray frequencies, inasmuch as the electric susceptibility for suitable media can be positive in these frequency ranges^{6,7}.

By adjusting such radiation to resonance with the energy required to excite some metastable state, the effect can be applied to achieve substantial population inversion at these higher frequencies. Such selective pumping to the metastable state would improve pumping efficiency over either flash or electron-beam excitation alone. The medium in which the radiation is produced can be, but does not have to be, the same as the system being pumped.

One of us (R. S.) thanks S. Wiesner for critical discussions and M. Schwartz for support.

Intermolecular basis of odour

THREE quite different theories of odour discrimination are in favour at present. The 'site filling theory' of Amoore¹ relates molecular shapes to odour types and identifies some classifications as primary. The penetration and puncture theory of Davies² develops a physical model for impulse transmission. The key physical properties involved are the molecular size and the adsorption coefficient between air and a lipid-water interface. Wright³ has correlated vibrational frequencies in the far infrared with the quality of odour.

All these theories, however, do agree that although there is no clear relationship between the functional group(s) present and odour, the mechanism of interaction with the receptor(s) must be physicochemical involving either electronic, vibrational or rotational forces or any combination of these.

Here I present evidence which implicitly correlates both odour quality and odour thresholds with the depth of the intermolecular potential energy well formed between the odour-producing molecule and the unknown receptor site.

There is a relationship between the depth of the pairwise intermolecular potential energy well and the normal boiling point of a substance⁴; the depth of the well increases linearly with the boiling point (K). The negative derivative of this potential with respect to intermolecular separation is a measure of the electronic interactive force.

In the case of the interaction of a molecule with the receptor site the depth of the potential well formed will depend on the nature of the charge distribution of the odorant molecules. If only one basic type of receptor site is assured, with numerous formal charges, then some correlation should be possible between the normal boiling point of a molecule and its odour type. I have found the normal boiling points for 253 of 418 ethereal, camphorous, minty, almond, aromatic, floral and musk compounds listed by Amoore¹. Table 1 summarises the results giving average

Table 1 Average boiling points and standard deviations of different odour classes

Class*	Average boiling point (K)	s.d. (K)
Ethereal	346	66
Camphorous	450	40
Minty	453	36
Almond	457	45
Aromatic	482	49
Floral	498	48
Musk	636	81

* Pungent and putrid classes were not considered since these can be understood in terms of highly reactive functional groups.

values and standard deviations for each odour class. Ethereal compounds have the lowest boiling points with the musks at the other extreme. Both of these have average values quite far removed from those of the other groups (camphorous, minty and almond) whose average values are so close to one another as to be indistinguishable. This is interesting in that many of the compounds possess more than one of these three odours at a time. The lowest boiling compound of all the molecules is ethylene (ethereal, 169 K). Very low boiling compounds such as CO (81 K), CH₄ (112 K), O₂ (90 K), N₂ (77 K) have small interactive electronic forces with the receptor site and hence are odourless.

A better correlation is achievable if boiling points of compounds with the same functional group are classified separately. Table 2 lists saturated halides in terms of increasing boiling points. If one assumes that for the halides 377 K is the cutoff for ethereal compounds then one obtains

Table 2 Boiling points (b.p.) and odour classifications (o.c.) of alkyl halides

Alkyl halides	b.p.	o.c.*	Alkyl halides	b.p.	o.c.
Methyl chloride	249	E	Pentachloroethane	435	E

Boiling point at 1 atm (K). Some of the values have been extrapolated from reduced pressure boiling points. With some of the musks we can only give an inequality but these are reasonable.

* Odour classification code. E, ethereal; C, camphorous.

$\lambda^2 = 0.25$ and $P = 0.38$. Similar success is obtained when looking at other functional groups.

In Table 3 the negative log of the odour threshold concentration is computed for a series of saturated alkanes and compared with experimental values⁹. The thresholds (negative log of the concentration) are computed by assuming the correct value for ethane and that the other thresholds should vary by the proportion of their boiling point (K) to that of ethane (K). These results give a high correlation $\lambda^2 = 1.22$ and $P = 0.005$. Since the potential well depth increases with increasing boiling point, fewer molecules would be needed to trigger an impulse. Similar success is obtainable with other classes of molecules.

Table 3 Computed compound with experimental values of the negative log of the threshold concentration for a series of alkanes

Compound	T (K)	Calculated threshold*	Experimental threshold†
Ethane	185	—	3.08
Propane	231	3.85	3.31
Butane	273	4.55	4.28
Pentane	309	5.14	5.32
Hexane	342	5.69	5.57
Heptane	371	6.18	5.79
Octane	399	6.64	6.21
Nonane	423	7.04	6.33
Decane	446	7.43	7.10
Undecane	468	7.79	6.83
Dodecane	488	8.12	6.66
Tridecane	507	8.44	6.64

* Negative log of the threshold concentration (mol l^{-1}) calculated by taking $(T_b(\text{K}) \text{ system}) / (T_b(\text{K}) \text{ ethane}) \times (\text{negative log of ethane threshold})$. (T_b = normal boiling point).

† Negative log of experimental threshold concentration (mol l^{-1}) determined from values in ref. 5.

The theory outlined above fits in with the Davies theory, since it may be the mechanism by which the odorant molecule opens up the space in the cell membrane to induce charge flow. The theory above also gives support to Wright's vibrational correlations since the vibrational energy level separations reflect the shape of the potential energy curve and hence the rate of energy transfer. It appears that the difference between minty, camphorous, and almond odours has more to do with the shape of the potential energy curve than with the depth of the well. In these terms the nearly infinite nuances of odour can be understood.

Randebrock⁶ has suggested that the α -helix protein

molecule may be a receptor site for odour. It should now be possible using electrostatic models based on quantum mechanical charge densities for such molecules to see if a correlation of potential energy surface and odour can be established for this or any other suspected receptor molecule.

Coevolution of Danaid butterflies with their host plants

MALE butterflies of the nymphalid subfamily Danainae possess pheromone disseminating organs (hairpencils) the secretions of which function as female flight arrestants or aphrodisiacs^{1,2} and in some case as female attractants¹. The hairpencil secretions of a number of Danaid species contain dihydropyrrolizine derivatives³⁻⁸ which are obtained from pyrrolizidine alkaloid plants by adult feeding^{6,7}. A dihydropyrrolizine ketone isolated⁸ from the hairpencils of *Danaus gilippus herenice* Cramer has been shown to be the flight arrestant or aphrodisiac pheromone in this species^{3,9} and we believe that the related dihydropyrrolizines found on the hairpencils of other species may perform a similar function. We propose here one possible explanation for the unusual dependence of male Danaid butterflies on pyrrolizidine alkaloid plants.

Many Danaid species apparently store in their body tissues vertebrate heart poisons (cardenolides) sequestered by their larvae from food plants^{10,11} which are found primarily in the cardenolide containing sections of the Asclepiadaceae and Apocynaceae¹². The Danainae's association with cardenolide plants is considered to be an important factor protecting them from vertebrate predators.

The pyrrolizidine alkaloid plants most commonly sought out by adult males are species of the Boraginaceae which contain the 1,2-unsaturated allylic ester type alkaloids¹³ for which metabolism into the hairpencil dihydropyrrolizines is readily envisaged. Other sources of this particular type of pyrrolizidine alkaloid which are visited by male Danainae, are the tribes Senecioneae and Eupatorieae of the Compositae and the genus *Crotalaria*¹⁴ of the Leguminosae¹⁵.

We suggest that the Danaid's use of, and dependence on, pyrrolizidine alkaloids may have developed during a period when these alkaloids were constituents of their larval food plants. Based on current views of the phylogeny of the plants concerned we propose that the early larval food plants contained both pyrrolizidine alkaloids and cardenolides and that they, perhaps under pressure of insect predation (see below), split into a cardenolide and a pyrrolizidine alkaloid branch. The Danainae then retained protection from predators by evolving as larval feeders on the cardenolide plants with the males visiting pyrrolizidine alkaloid plants to obtain their pheromones.

Our proposal is consistent with the phylogenetic classifications of Cronquist¹⁶ and Takhtajan¹⁷ if the ancestral food plants occurred early in or before the evolution of the subclass Asteridae and diversified according to the scheme shown in

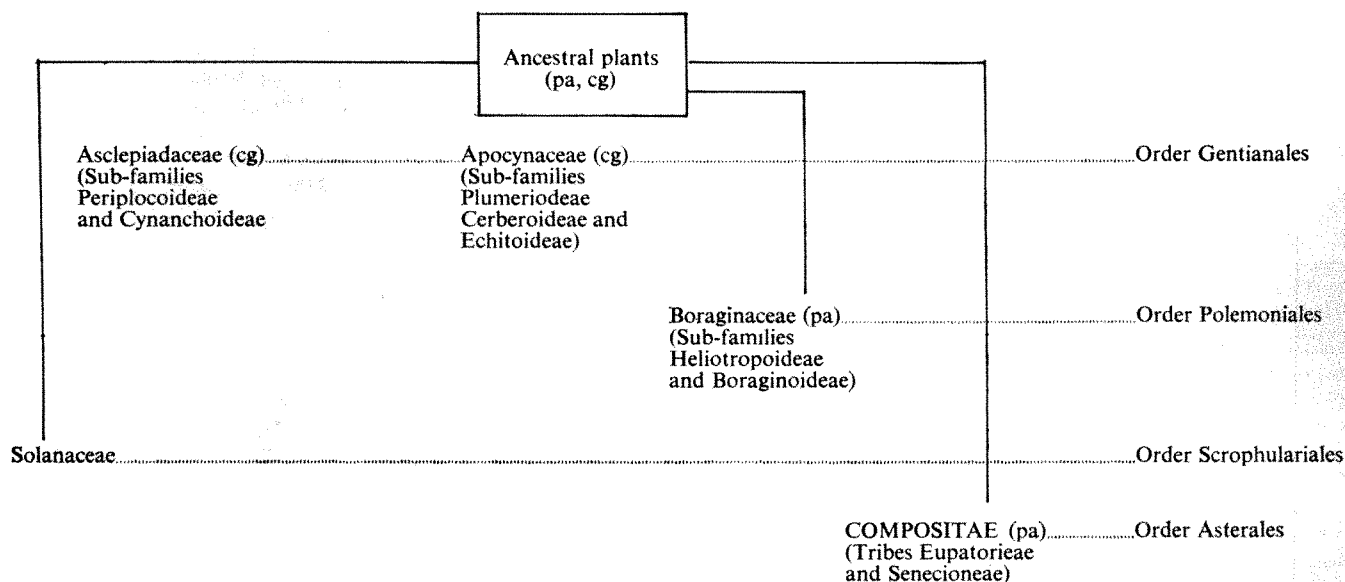

Fig. 1 Proposed origin of the pyrrolizidine alkaloid- and cardiac glycoside-containing sections of the plant families in the subclass Asteridae with which Danaid and Ithomiid butterflies associate showing the distribution of cardiac glycosides (cg) and pyrrolizidine alkaloids (pa).

Fig. 1. Of the pyrrolizidine alkaloid plants which male Danaids visit, only *Crotalaria* species are found outside this subclass. They may be an earlier branch of the postulated ancestral host plants (compare with Takhtajan¹⁶) or represent an independent development of this particular type of pyrrolizidine alkaloid.

Divergence of the original food plants might have occurred as a result of the dependence of the early Danaids on pyrrolizidine alkaloids and cardenolides. Because of their importance to the Danainae both of these substances, or related marker substances, probably provided the cues for locating, and the stimulus for ovipositing on, the early larval food plants. This would have favoured the survival of plants which were naturally deficient in one or other of these chemicals.

The possibility of co-occurrence of cardenolides and pyrrolizidine alkaloids in progenitor species is exemplified by *Urechites karwinskyi*, Mueller, (Apocynaceae) (also referred to as *Fernaldia pandurata* (A.D.C.) Woodson¹⁷). A dihydropyrrolizine closely related to the Danaid hairpencil dihydropyrrolizines has been isolated from this toxic plant¹⁸ and other toxic species of the genus are known to contain cardenolides^{19,20}. We regard as highly significant the fact that *U. karwinskyi* is used as a larval food plant by a primitive Ithomiid butterfly, *Tithorea harmonia salvadores* Staudinger, whose larvae bear a close affinity to those of certain Danainae²¹. The subfamily Ithomiinae (Nymphalidae) is closely related to the Danainae²¹ and in common with male Danaids, male Ithomiids are attracted to, and feed on *Heliotropium indicum* L. (Boraginaceae), which contains pyrrolizidine²². Their larvae feed primarily on Solanaceae¹² but notable exceptions are species of the genus *Tithorea* whose

larvae feed, like certain of the Danainae, on Apocynaceae²¹. The *Tithorea harmonia salvadores*–*Urechites karwinskyi* association may therefore be a conservative development from, and provide a model for, the ancestral association we have proposed.

By considering the pyrrolizidine plants visited by adult males to have evolved from earlier larval food plants the present behaviour of the Danaids and the development of the hairpencil chemicals as female flight arrestants and attractants can be more readily understood. Thus, it is envisaged that mating of early Danaids occurred in the vicinity of the larval food plants and that males subsequently developed the means of storing and disseminating volatile pyrrolizidine alkaloid-derived plant substances then used by the females to locate the larval food plants. By disseminating these substances in the vicinity of a female in flight they would be able to make her settle and thus effect mating in a place remote from the larval food plant. Such a development would have offered an expanded habitat for the insects and would have become essential for their survival during divergence of the original food plants when the females were being selected for their ability to find and oviposit on cardenolide plants, which gave their offspring protection from predators, while the males were seeking out pyrrolizidine plants.

Males make up over 90% of the butterflies attracted to pyrrolizidine plants but a small proportion of females of some species also visit them^{6,23} (Table 1). This may be the remnant of a behaviour pattern and olfactory acuity associated with location of the earlier larval food plants which has not yet been completely lost from the gene pool of the females. *Tithorea* species again seem to be exceptional and, in agreement with the

Table 1 Typical collections of Ithomiinae attracted to *Heliotropium indicum* L.

conservative development we have proposed for Tithorea, both males and females are attracted (Table 1).

The existence in the past of plants containing pyrrolizidine alkaloids and cardenolides might explain Rothschild's observation²⁴ that certain moths of the families Arctiidae and Ctenuchidae also utilise both these phytochemicals.

We thank A. Muyshondt for information on the larval food plant of *T. harmonia salvadorens* and G. Goss and D. Black for comments. T.E.P. was supported by a National Science Foundation grant.

'Fimbriae' in the fungus *Ustilago violacea*

LONG fine hairs, called fimbriae¹, or pili², are commonly found attached to the cell walls of Gram-negative bacteria², but do not seem to have been reported in other organisms. We report here that the yeast-like sporidial cells of the anther smut fungus *Ustilago violacea* also produce fimbriae. At present the use of the term fimbriae for these fungal hairs merely denotes a close morphological and developmental similarity to the bacterial structures; however, preliminary investigations of the fungal 'fimbriae' indicate that there may be chemical and functional similarities too.

The fimbriae of *U. violacea* can readily be observed when sporidia from a log-phase population are washed at least three times in particle-free distilled water, and then air dried on a Formvar-coated grid before shadowing with

tungsten oxide at an angle of 18–25°. The fimbriae resemble bacterial fimbriae in the following ways.

(1) They are of similar dimensions, being about 1–10 μm long and 60–70° A in diameter. They are curved and flexible and do not branch or taper. The apparent branching of the fimbriae in Fig. 1 is common and occurs when they twine together to form multistranded 'cables' which may dissociate into the individual strands. They resemble the curved fimbriae of *Vibrio* spp.³ rather than the rigid, straight type I characteristic of *Escherichia coli*² and *Salmonella*⁴. We cannot be certain whether or not they have the hollow helical structure characteristic of these type I and F fimbriae, but apparently absent from the *Vibrio* forms.

(2) Fimbriae originate below the cell wall and penetrate through it. Freeze-etched preparations show particles of about 70–100 Å on the outer surface of the plasma membrane and corresponding projections on the inner surface of the cell wall. Sectioned walls are traversed by fibrils 70–100 Å in diameter which apparently are fimbriae passing through the cell wall.

(3) As in bacteria, populations of cells in logarithmic growth are the most fimbriated, while stationary phase cells are hairless. Broth cultures are much more fimbriated than cultures from nutrient agar plates. But, even in heavily fimbriated populations, the quantity of fimbriae on individual cells appears to vary greatly from 0 to more than 200. Similar variation has been found in bacteria². The fimbriae seem to be susceptible to mechanical damage and may contract into tight coils on the surface of most cells in particular regions of a grid. Similar coils are produced on all cells by treatments with various reagents including the fixatives glutaraldehyde and formalin.

(4) The fimbriae can be removed easily from cells by violent mechanical agitation in a blender, by sonication or by centrifugation through a viscous liquid (for example, 40% sucrose). In bacteria, fimbriae regenerate very rapidly, beginning about 10 min after reinoculation into nutrient medium². Similar rapid regeneration occurs in *U. violacea* as the fimbriae begin to appear in less than 1 h and reach normal length (about 3–7 μm) in less than the cell cycle time of 5 h. Again as in bacteria the fimbriae are constantly produced and shed by cells so that many free unattached fimbriae can be observed in all cultures.

(5) Type I bacterial fimbriae are composed mainly of a protein called pilin². The fimbriae of *U. violacea* are completely digested by treatment with pronase and thus contain protein throughout their length. Treatments with ether, DNase or RNase do not affect them, and they are not stained by phosphotungstic acid (PTA) or ruthenium red. We conclude that they may be largely and perhaps entirely composed of protein.

We are examining other yeasts and yeast-like fungi to determine whether such fimbriae are common. No species we have investigated so far reveals the long fimbriae of *U. violacea* and indeed even the strains of this species maintained by the Centraalbureau voor Schimmelcultures, Baarn, The Netherlands, show fewer fimbriae. However, short hairs and other extensions are produced by some yeasts in genera such as *Lipomyces*, *Nadsonia* and *Saccharomyces*. Thus the presence and structure of surface hairs may have significance for the taxonomy of yeast-like fungi. We have observed short hairs in *Saccharomyces cerevisiae* which are probably extracellular extensions of the microfibrils that Moor and Mühlethaler observed arising from particles on the plasma membrane and penetrating into the wall⁵. These hairs are more frequent on flocculent strains than on non-flocculent forms.

What role do the fimbriae play in the growth of the smut cell? Even though bacterial fimbriae were described about 20 yr ago the functions of the several kinds are largely unknown, except for the F fimbriae which are thought

Fig. 1 Metal shadowed preparation of a sporidium of *Ustilago violacea*, showing many long flexible fimbriae. The apparent branchings are always associated with reduction in width and are due to dissociation of multistranded 'cables'. The bar represents 1 μ m.

to transport DNA molecules from F⁺ or Hfr cells to F⁻ recipients. Brinton² has suggested that the other fimbriae are involved in transport of metabolites or informational macromolecules, colicin-like killing of other cells, or simply adhesion to surfaces. He has also suggested that some fimbriae are rod shaped viruses being released from the cell in a manner similar to the release of the DNA male phages.

The function of fungal fimbriae is at present a matter of speculation. The suggestions made above for bacteria are equally applicable to the yeast-like *Ustilago* cells. One possible role would be in the mechanism of conjugation. We have shown that development of the conjugation bridge depends on mutual information transfer at an early stage in courtship^{5,6}. We speculated that such information transfer was mediated 'probably through hairs on the glycocalyx'. The fimbriae described here provide a firm morphological basis by which this information transfer could occur, as we have evidence showing that fimbrial connections are formed between the cells in the early stages of the conjugation process. We are investigating the synthesis and structure of the fimbriae in *U. violacea* and their possible role in conjugation. A full account of this work together with a description of fimbriae in other yeast-like species will be published elsewhere.

We thank Dr J. E. Cummins for advice.

In vivo hybridisation of human tumour and normal hamster cells

It is exceedingly rare for neoplasms to be invasive and metastatic when grafted in xenogeneic hosts¹. During the past 7 yr, we have on numerous occasions observed the production of invasive and metastatic tumours in hamsters soon after injecting human cancer cells of diverse histopathology into their cheek pouches²⁻⁷. We have interpreted this biological phenomenon as due to the *in vivo* fusion of the human tumour with normal hamster host cells²⁻⁸, although the involvement of oncogenic viruses was not excluded. Recently, other evidence supporting the hybridisation of tumour with normal cells *in vivo* has appeared⁹. The significance of such events in the neoplastic process, however, has yet to be appreciated.

It is our view that such *in vivo* cell hybridisations in xenogeneic and perhaps also in isogenic systems are a means by which neoplastic cells can progress to more advanced states of malignancy, as exhibited by the properties of invasiveness and metastasis⁸⁻¹⁰. Utilising advances made in methods for individual chromosome identification, we have now obtained karyological evidence suggesting the *in vivo* fusion of transplanted human cancer cells with putatively normal hamster cells, resulting in the formation of very lethal neoplasms.

As performed in previous studies²⁻⁷, a portion of an astrocytic glioma (Fig. 1a) from the brain of a 44-yr-old female was injected as a fine cell suspension into the cheek pouches of nine male golden hamsters (*Mesocricetus auratus*) weighing 50-60 g. No immunosuppressive host-conditioning measures were used. Fourteen days later, a large tumour measuring 1.1 cm in diameter was confirmed in only one animal's cheek pouch. The microscopic appearance of the tumour graft did not resemble that of the original human neoplasm (Fig. 1b). Four weeks after transplantation, this animal expired with widespread metastasis to all major organs, including the lungs (Fig. 1c) and the adrenals (Fig. 1d). Aliquots of the first passage cheek pouch tumour were then grafted to other hamsters, in their cheek pouches or intraperitoneally, as well as explanted in cell culture. Our cell culture techniques have been described elsewhere¹¹. Both *in vivo* and *in vitro*, a continuously propagable tumour cell line resulted, and has been termed GB-749. Either growing in the cheek pouch or in the ascites form, GB-749 has been uniformly lethal for its hamster host.

GB-749 cells from the fifth ascites and fifteenth cheek pouch tumour passages were placed in culture for 6 and 18 d, respectively, before collecting for cytogenetic analysis; the cancer patient's peripheral blood cells were treated similarly, except for the addition of phytohaemagglutinin, according to standard cytogenetic methods¹². Counting the chromosomes of 50 GB-749 cells of each passage revealed that between 52 and 60% of the cells had a modal range of 58-60 chromosomes. Twenty cells of each transplant generation were karyotyped after banding the chromosomes by the trypsin-Giemsa method¹³, and all of the aneuploid tumour cells examined contained both hamster- and human-like chromosomes. The karyotype of a representative GB-749 cell is reproduced in Fig. 2a, showing chromosomes with banding patterns typical for both human and hamster chromosomes.

Table 1 Frequency of human and hamster chromosomes (single or pairs) in 20 karyograms of GB-749 hybrid tumour cells

		Fifth ascites passage																				
Chromosome No.	X	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
Hamster	18	17	12	4	11	20	20	19	14	13	20	19	20	16	19	19	20	17	19	19	15	2
Human	0	2	13	4	0	1	1	2	0	1	0	7	3	0	0	0	0	0	10	0	0	14

		Fifteenth cheek pouch passage																				
Chromosome No.	X	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
Hamster	10	10	17	5	13	19	20	18	16	19	18	19	20	18	20	20	20	17	18	20	20	4
Human	0	0	10	8	0	0	0	1	0	5	1	1	0	1	0	1	1	0	7	0	0	15

Table 1 shows the frequency of each hamster and human chromosome identified in the fifth and fifteenth hamster transplant passages of GB-749. Chromosomes with a hamster-like banding pattern predominated in both cell generations. A significant number of the human-appearing chromosomes, however, No. 2, 3, 11, 18, and 21, were present among the 20 karyotypes examined at random.

The resemblance of the banding patterns of the human-like chromosomes most frequently found in GB-749 to their counterparts in the patient's peripheral lymphocytes is demonstrated in Fig. 2b. At times, the hamster's chromosome No. 9 looked very similar to the human chromosome No. 11 and 12, but the ones chosen in this figure clearly indicate the presence

of the human 12 chromosome in GB-749. Of additional interest is the occurrence of pronounced satellites on the short arms of the 21 chromosome, both in the patient's peripheral blood cells (H) and in the GB-749 tumour (T) produced in hamsters and serially propagated in these animals and in cell culture. In addition, this chromosome had a centromeric banding pattern typical for the human 21 and distinct from that of any normal hamster chromosome of this size and form. Our recent identification of small acrocentric chromosomes, however, with similar distinguishing features in mouse melanoma/hamster cheek pouch hybrids produced *in vitro*, and in two other presumptive human/hamster hybrid tumours established *in vivo*¹⁰, raises the question of whether this might represent a marker chromosome for such tumours in the hamster, and not necessarily be of human derivation. We are cognisant that rearrangements of hamster chromosomes could have resulted in banding patterns similar to those of the chromosomes identified as human by this morphological method.

The frequency of spontaneous cell fusion *in vitro* has been reported to be very low for most cell types combined, and has been estimated to occur at 1×10^{-6} to 5×10^{-6} (ref. 14). The increased frequency of somatic cell fusion induced with the aid of myxoviruses^{15,16} raises the possibility that the *in vivo* hybridisation suggested in this human tumour transplantation and in previous studies²⁻⁷ may have been influenced by tumour- or host-borne fusing agents.

It is usual for many somatic cell hybrids to lose selectively the chromosomes of one of the parents while the chromosomes from the other remain dominant in number. In the case of human/rodent cell combinations, it is the human chromosomes which are preferentially lost¹⁷⁻¹⁹. Although this is the only reported case of a putative *in vivo* heterospecific hybridisation involving karyological analysis of the hybrid progeny, it seems that a number of relationships found in cell fusion *in vitro* are true for the *in vivo* situation. Our human/hamster cell fusion results indicate that pronounced chromosomal segregation occurs following hybrid formation, where the human chromosomes are preferentially lost. Further, malignancy, when associated with the human parental cells which experienced chromosomal loss, can be expressed in the hybrid progeny, even after a relatively long sojourn in the animal host.

The animal host would be expected to eliminate any human chromosomes in the hybrid tumour cells, particularly if these could restrict the hybrid tumour's viability. Yet, human chromosomes seem to have been retained in the hybrid tumour for at least up to 15 serial transplant passages, or a minimum of 18 weeks. Whether or not the portion of the human genome controlling malignancy required the retention of any particular human chromosomes or chromosomal fragments for the expression of malignancy in the hybrid, or the loss of some inhibitory genes, cannot be concluded on the basis of these data. It is nevertheless intriguing to follow the chromosomal constitution of a human/hamster hybrid tumour during extensive propagation in hamsters, and to explore to what extent the human genome is functional and being recognised by the hamster host.

As *in vivo* hybridisation seems to have permitted a human tumour to become adapted and unusually lethal in the hamster, we suggest that similar mechanisms may be implicated in human cancer, particularly when such fusing agents as parainfluenza viruses are prevalent in man. In the autochthonous tumour-

Human chromosomes No. 12 in GB-749 (T) and in the patient's blood (H) are also compared with hamster chromosome No. 9 (M).

bearing host, fusions of neoplastic with normal cells might provide the tumour with a means for reducing any tumour-specific antigenicity and thereby allow it to escape immunological surveillance mechanisms. In these terms, tumour progression by fusion would permit the neoplasm to circumvent the host's immunological controls. Conversely, fusing the tumour with other cells *in vitro* may provide a more suitable immunogen for the evocation of an immunological reaction against a tumour of advanced malignancy. Although still speculative, such considerations may offer other avenues for the immunological control of cancer.

Evolution of X-chromosome inactivation in mammals

It is now well established that in the somatic cells of mammals only a single X chromosome is active in coding for proteins, no matter how many are present^{1,2}, but the mechanism and evolutionary origin of this phenomenon still remain unsolved problems. Cooper³ suggested that the random inactivation of X chromosomes derived from either parent in eutherian mammals had evolved from a more primitive inactivation of the paternally derived X chromosome as seen in marsupials, and a possible mechanism for this evolution has been put forward⁴. Lifschytz and Lindsley⁵ further suggested that the inactivation seen in somatic cells had evolved from inactivation of both sex chromosomes in male gametogenesis, a phenomenon that is general in gametes of the heterogametic sex of many species.

All of these proposals have obvious merit, but in detail criticisms can be levelled at all. It may therefore help to consider the possible evolution of X chromosome inactivation more fully. It is reasonable to suppose that monoallelic activity of the X chromosome is connected in some way with its function as a sex chromosome. In germ cells of normal females both X chromosomes are clearly active⁶⁻⁸. Moreover, they are required to be so for normal ovarian function in both human and mouse^{9,10}. In males, if more than one X chromosome is present, as in XX and XXY males of various species, the germ cells die at the spermatogonial stage^{2,11}. The explanation that this is due to activity of all X chromosomes in male germ cells as well as female has recently been confirmed by the finding that loss of an X chromosome enables germ cells to survive in these animals¹². But, as previously mentioned, later in male gametogenesis the X seems to become inactive. Thus, the cycle of X chromosome activity is: somatic cells, single; female germ cells, double; late male germ cell, none.

Thus, the X chromosome clearly has a role in the germ cells. By contrast, sex determination in mammals is effected through the Y chromosome. In the presence of the Y chromosome the embryonic gonad is induced to become a testis¹³.

The testis then secretes testosterone which, in combination with the product of a certain gene, activates all genes required for male differentiation, so that the animal develops as a normal male¹⁴. In the absence of the Y the gonad becomes an ovary, testosterone is not secreted, and differentiation follows the female pattern. Thus, there is a simple switch mechanism controlling sex determination and

differentiation¹⁴. Mutation of the gene involved in response to testosterone leads to the syndrome of testicular feminisation, in which a genetic male has testes but no other signs of maleness, and fails to respond to testosterone. In the mouse the locus of this gene, called the *Tfm* gene, is on the X chromosome¹⁵. Hence, by Ohno's law of the conservation of the mammalian X chromosome¹⁶ it is probably X-linked in all mammals, and thus gives another function of the X chromosome in sex differentiation.

The sex chromosomes of present day mammals are typically clearly distinguishable, with a small Y and fairly large X, the variably active part of the X constituting roughly 5% of the genome¹⁶, although some species have other material (constitutive heterochromatin or autosomal material) attached to the X. By contrast, the sex chromosomes of lower vertebrates are commonly not distinguishable¹⁶. Thus, in evolution the mammalian Y must have lost material, and the X has perhaps gained some.

Concurrently, sex determining processes have evolved. Lower vertebrates respond to hormones in a way comparable to the mammalian response to testosterone, but in contrast to mammals sex determination is more labile, and sex reversal can be achieved by hormone treatment. In view of the response to testosterone one may suppose that a gene comparable to the *Tfm* gene was present early in evolution, before the sex chromosomes became morphologically distinct. The next stage was the formation of a small differential segment, containing in the Y the genes involved in testis formation. At this stage, the locus of the *Tfm* gene will have been present on both sex chromosomes, and genes concerned in ovarian function will have been distributed over both X and Y, interspersed with many genes not directly involved in sexual development (homologues of present X-linked genes). After this, the Y chromosome lost much of its material, including the homologues of the X-linked genes. There was then a dosage difference between males and females, which was corrected by X chromosome inactivation in somatic cells.

It is however difficult to envisage exactly how this inactivation first arose. As seen at present it is an all-or-none phenomenon. The inactivated chromosome (except for a possible small region escaping inactivation) is totally and irreversibly unresponsive to stimuli evoking transcription, and it seems unlikely that it could have evolved to this state by a gradual process. There seems no intermediate stage. But total inactivation of one X chromosome when previously two had been active would in effect result in functional monosomy for X-linked genes and monosomy in mammals is usually lethal¹⁷. Thus, the evolution of X inactivation would be easier to envisage if some duplication of genes had occurred first. This could have been achieved

Fig. 1 Suggested evolutionary origin of mammalian sex chromosomes. The position of the centromere, and the relative lengths of the dotted, shaded and white regions are purely diagrammatic and not to scale. The white regions are those postulated to be subject to inactivation in present mammals.

if the material lost from the Y chromosome had been transferred to the X, giving in effect a tandem duplication of the major part of the original X chromosome (Fig. 1). Female offspring which received such a duplicated X chromosome, either homozygously, or heterozygously with the original, would have excess X-linked genes, and hence would probably not be viable, unless the excess material were inactivated. Thus, one must also postulate that a mechanism for inactivation of X chromosomes had already evolved before the proposed Y-X transfer occurred. This, one must suppose, was the form of inactivation seen in late male germ cells, with the mechanism now modified so that it operated in somatic cells, but only on excess material. Such a system could have been selectively advantageous if the additional X chromosomal material was active and beneficial in female germ cells.

From this hypothesis of the evolutionary origin of X-chromosome inactivation at least two predictions can be made. One is that there should be a small region of the present mammalian X chromosome which is not subject to inactivation. This would be the original differential segment of the X, which by definition could have had no homologue on the Y. Therefore, it could not have been transferred from the Y to the X, and hence was never present in excess.

This does indeed seem to be the case in the human X chromosome. The Xg blood group locus is apparently not subject to inactivation in a normal X chromosome¹⁸. Moreover human XO individuals have a range of malformations, which seem to be due to deficiency of gene(s) located in the short arm of the X¹⁹ and in individuals with supernumerary X chromosomes the finger-ridge count, the stature and mental ability seem to vary additively with number of X chromosomes present²⁰. All these facts could be explained if a part of the short arm of the human X chromosome was not subject to inactivation, because it represented the original differential segment. It is not clear, however, whether such a region exists in other species. Chromosomally XXY males are known in a number of species and no clear pattern of abnormalities, except sterility, emerges². Females with the XO constitution are known in the pig²¹, the rhesus monkey²², and the cat²³ and in each there was at least one abnormality also seen in human XOs. But in XO animals of several rodent species (mouse, black rat *Rattus rattus*²⁴, *Akodon*²⁵ and *Microtus oregoni*²⁶) no somatic abnormalities were noted, and some were fertile. Possible explanations for an apparent lack of

Table 1 Human X-linked diseases existing in more than one form

Probably at least two gene loci

The numbers are the catalogue numbers given by McKusick²⁹.

the original differential segment in rodents are that in the course of evolution it has been transferred to an autosome, or has been duplicated and then become subject to inactivation.

A second and important prediction is that there should be some evidence of duplication of gene loci on present mammalian X chromosomes. It is to be expected that during evolution the originally duplicate genes will have mutated and diverged, but some evidence of similarity should still remain. Only the human and the mouse X chromosomes are genetically at all well known, the human having far more known X-linked genes than the mouse. McKusick²⁷ pointed out that several X-linked diseases exist in more than one form. The various forms could either be due to different mutant alleles at the same gene locus, or to the involvement of more than one locus for each disease. This point can only be tested conclusively by chromosome mapping. From the latest evidence²⁸ it is highly probable that there are at least two gene loci involved in each of four X-linked diseases: colour blindness (protan and deutan), haemophilia (A and B), muscular dystrophy (Duchenne and Becker), and retinal degeneration (retinoschisis and Norrie's disease) (Table 1). In addition, there are at least eleven other diseases listed by McKusick²⁹, which exist in more than one form, and hence are possibly caused by duplicate loci. McKusick lists 150 X-linked conditions, 86 of which he considers well established. This must be only a small fraction of the probably several hundred genes on the human X chromosome. Hence it is hardly to be expected that both members of every pair of duplicate genes would have been discovered, and the present evidence must be considered quite good. The weakest point is that the similarity between pairs of diseases has been judged at the clinical level, and molecular evidence for the similarity or otherwise of the proteins involved is lacking. By contrast, in the mouse only about 28 X-linked genes are known, thought to be at about 21 loci³⁰, and there is as yet no evidence of duplication.

Thus, the supporting evidence from man is sufficient to make the hypothesis of evolution of X chromosome inactivation through Y-X transfer well worthy of further consideration. To reiterate, the hypothetical sequence of events was: (1) formation of a small differential segment, carrying testis-forming genes in the Y, from previously undifferentiated sex chromosomes; (2) inactivation of the sex chromosomes during male gametogenesis, but full activity of both homologues in female germ cells; (3) transfer of a large part of the homologous region of the Y to the X, and concomitant alteration of the inactivation process, so as to inactivate all excess X chromosomal material in somatic cells, while retaining full activity in female and early male germ cells, and complete inactivity in late male germ cells; (4) slow divergence of the two halves of the duplicated X by mutation and selection.

Further evidence could be obtained from studies of X chromosome anomalies in a range of mammalian species. Human X chromosome linkage data could be re-examined with the possibility of duplicate loci in mind, and at the molecular level proteins coded by X-linked genes could be studied for evidence of duplications.

A possible role for prolactin in control of steroid secretion by the human Graafian follicle

PROLACTIN constitutes part of the luteotrophic complex necessary for the maintenance and secretory activity of the corpus luteum in the rat^{1,2}, mouse³, rabbit⁴, hamster⁵, ferret⁶, pig⁷ and sheep⁸. Recent evidence suggests, however, that prolactin may have little to do with luteal function in women⁹⁻¹⁵. Nevertheless, it is still possible that prolactin could play a 'permissive' role, as in other species, where alterations in peripheral blood levels, within limits, have little effect on luteal activity. In an attempt to gain more insight into the possible role of prolactin in controlling ovarian activity in women, we have studied the production of steroids by human granulosa cells growing in tissue culture, and the effects of the addition or neutralisation of human prolactin in the culture media. We report that the production of progesterone by human granulosa cells *in vitro* requires low physiological concentrations of prolactin whereas high concentrations are inhibitory.

Ovaries, endometrial biopsies and peripheral blood samples were obtained from patients aged 21-48 yr who were undergoing surgery for gynaecological disorders. The stage of the menstrual cycle was assessed from the date of the last menstrual period, the concentrations in plasma of luteinising hormone (LH), follicle stimulating hormone (FSH) and progesterone, endometrial histology, and the presence or absence of a corpus luteum. Only follicles from morphologically normal ovaries were used as the source of granulosa cells in this study.

Antral follicles were dissected out of the ovary within 2 h of ovariectomy and the fluid aspirated by syringe. The follicular fluid and peripheral plasma sample were stored at -20°C until assayed for prolactin and progesterone by

specific radioimmunoassays (RIA). Prolactin concentration is expressed as ng ml^{-1} Friesen prolactin of which $1 \text{ ng} \equiv 20 \mu\text{U}$ MRC Standard 71/222. The Friesen prolactin preparation was 90% pure and the human pituitary hormone contaminants were found by RIA to be negligible: growth hormone (HGH), HLH, HFSH, all $<0.4\%$ and the concentration of human placental lactogen (HPL) undetectable. The collapsed follicle was slit open and the granulosa cells scraped into culture medium. An aliquot of the cell suspension was counted and the viability determined¹⁶. The follicle wall was placed in fixative for subsequent histological examination to ensure that the basement membrane was still intact. The cells were layered on to 18 mm^2 coverslips and cultured for 10–14 d as previously described¹⁷. The culture medium was replaced every 24 h and stored at -20°C until assayed for progesterone. The variation ($\pm \text{s.e.m.}$) in the production of progesterone between replicate cultures for all treatments was found to be 6.77 ± 1.45 .

Neutralisation of prolactin in the culture medium by the addition of rabbit anti-human prolactin serum, at a dilution which did not cross react with HPL, HGH, HLH or HFSH, caused a significant decrease in progesterone production as compared to the cultured control (Fig. 1). To

Fig. 1 Progesterone production by luteinised granulosa cells in a culture medium where the endogenous prolactin was neutralised with anti-human prolactin serum. The cells were collected from a single late follicular phase preovulatory follicle. The concentration of endogenous prolactin in the culture medium before the addition of rabbit anti-human prolactin serum was 5.1 ng ml^{-1} . After precipitation of the prolactin-anti-prolactin complex the concentration was $<0.2 \text{ ng ml}^{-1}$. The concentrations of progesterone in the control were determined with either normal rabbit serum, or rabbit anti-bovine serum albumin added to the culture medium at the same dilution (1/500) as the antiserum used in the anti-rabbit culture treatment. There were no significant differences in the production of progesterone between the control culture which were found to be within the precision achieved in replicate cultures. *a*, Control; *b*, anti-prolactin, $P < 0.01$.

confirm that free prolactin in the culture medium had been completely neutralised by the antiserum, the anti-prolactin-prolactin complex was precipitated out using a solid phase second antibody; the concentrations of LH and FSH in the medium were unaltered whereas prolactin was undetectable.

Addition of human prolactin to the culture medium had no effect on progesterone production if the final prolactin concentration did not rise above 20 ng ml^{-1} ; the mean concentration of prolactin in the peripheral blood of women during the cycle is $15 \pm 1 (\pm \text{s.e.m.})^{10}$. When the concentrations in the culture medium were increased from 25 to 100 ng ml^{-1} , there was a progressive decrease in the daily progesterone production (Fig. 2). This inhibitory effect persisted, even when the LH and/or FSH concentrations

Fig. 2 Relationship between the concentration of prolactin and the total progesterone production by human granulosa cells *in vitro*. Granulosa cells were collected from one late follicular phase preovulatory follicle. Each point is the mean result of duplicate cultures. Total progesterone production is that achieved by 10^6 granulosa cells in 11 consecutive daily changes of culture medium.

were increased 50-fold, and it could be obtained with granulosa cells collected from follicles at any stage of the menstrual cycle. In contrast the soluble non-protein fraction of the added prolactin solution did not inhibit the production of progesterone by human granulosa cells *in vitro* as compared with the controls.

Fig. 3 Changes in concentration and content of prolactin in follicular fluid with respect to follicle size. Vertical bars represent 1 s.e.m. Circles show prolactin concentration (ng ml^{-1}); bars show prolactin content (ng).

Prolactin was assayed in 110 samples of follicular fluid collected at various stages of the cycle. The mean concentration (\pm s.e.m.) was 20 ± 5 ng ml⁻¹ for all sizes of follicle. The increase in the prolactin content of the follicle was correlated with the volume of follicular fluid (Fig. 3). The prolactin concentrations during the late follicular phase of the cycle were, however, significantly lower than at any other time of the cycle with the exception of the early luteal phase (Fig. 4).

Fig. 4 Changes in the follicular fluid concentrations of prolactin and progesterone related to the stage of the menstrual cycle. The vertical bars represent 1 s.e.m. (M-EF; MF; LL; represent menstruation-early follicular, mid follicular and late follicular phases, and EL, ML and LL represent early, mid and late luteal phases.) *** $P < 0.001$; ** $P < 0.01$; * $P < 0.05$; ° $P < 0.001$.

These *in vitro* experiments suggest that high concentrations of prolactin within the follicular fluid may actually depress progesterone secretion by the granulosa cells. This might provide an explanation for the fact that galactorrhoea with high prolactin levels is commonly associated with amenorrhoea¹⁸, and that if the prolactin levels are lowered by treatment with CB 154, ovulation and menstruation recur^{19,20}. It is well recognised that post-partum lactation can inhibit ovulation in women and other animals^{18,21}, although the mechanism has never been explained.

Although there are now numerous descriptive accounts of the changing hormone levels in blood and urine throughout the menstrual cycle, we do not really understand what factors are responsible for the formation, maintenance and regression of the human corpus luteum. This is an area of great potential interest for the development of new forms of contraception. The *in vitro* results presented here cast doubt on the simplistic view that LH is the only gonadotrophin necessary for luteal maintenance¹⁵, and suggest that prolactin is also involved. Furthermore, it seems probable that the gonadotrophic content of the follicular fluid may have important consequences for the secretory activity of the granulosa cells both before and after ovulation.

We thank Dr R. V. Short for his advice in the planning of these experiments and in the preparation of this manu-

script. We thank Dr W. M. Hunter and Mr J. Bennie for the LH and FSH radioimmunoassays, Dr H. Friesen for the supply of purified human prolactin, and Mr L. McKenzie for the histology. A. S. McN. acknowledges financial support from the Wellcome Foundation.

Anatomy of an identified serotonin neurone studied by means of injection of tritiated 'transmitter'

THERE is an identifiable serotonin-containing neurone in each cerebral ganglion of the snail *Helix pomatia*¹. Electrophysiological evidence suggests that each neurone sends a process into each cerebro-buccal connective^{2,3}, and that monosynaptic connections are made in each buccal ganglion with other large identifiable neurones³. Because this neuronal system seems to offer a unique opportunity to study the proposed transmitter role of serotonin^{3,4}, it is important to obtain direct information on the localisation and morphology of the presynaptic endings of the serotonin cell. This is not possible with dye⁵ or metal ion⁶ injection techniques, which do not seem to mark processes of the

serotonin neurone at distances of more than a few millimetres from the neurone perikaryon.

In this study we injected tritiated serotonin, or its precursor 5-hydroxytryptophan, into the perikaryon of one of the identified symmetrically placed, serotonin neurones and, after allowing time for the radioisotope to pass along the processes of the neurone, the tissue was prepared for light and electron microscope autoradiography.

The tips (diameter 1 to 3 μm) of glass microelectrodes were filled with a solution of uniformly tritiated serotonin (5-hydroxytryptamine creatinine sulphate) or 5-HTP (DL-5-hydroxytryptophan) (Radiochemical Centre, Amersham). Solutions were prepared by evaporating to dryness 1 mCi of radioactive solution and redissolving in a small volume (0.01 ml) of distilled water. (The isotope specific activities were: serotonin 11 Ci mmol^{-1} and 5-HTP 7 Ci mmol^{-1} ; concentrations of the injection solutions were approximately 0.9 mM and 1.4 mM, respectively). Electrodes were selected by measuring isotope release from the tip into 0.2 ml of snail physiological solution⁷ after passing 10 nA positive square wave pulses of 100 ms duration at 5 Hz for 10 min. Electrodes releasing sufficient isotope to yield 5,000 to 20,000 c.p.m. (measured in a total volume of 10 ml including 9.8 ml of scintillation fluid, counted on a Packard Liquid Scintillation Spectrometer) were found to be suitable for intracellular iontophoresis.

Either the left or right giant serotonin neurone was impaled and positive pulses applied to the electrode for 1 to 2 h; generally 10 to 20 nA pulses of 100 ms duration at 5 Hz were used. The preparation was continuously washed with physiological solution. The direction of flow was from the buccal ganglia and lip nerves towards the cerebral ganglia, thus avoiding contamination of the areas suspected of containing processes and endings of the neurone. During the period of injection, the resting potential of the neurone decreased to between 0 and 10 mV, but

Fig. 1 Micrographs of autoradiographs of a right giant serotonin neurone injected with tritiated serotonin. The areas shown in *a* and *b* are indicated in Fig. 2. *a*, Axon of the serotonin neurone which runs in the contralateral cerebral ganglion. Approximately 25 small branches of this axon (some arrowed), which are shown in different degrees of oblique and transverse section, can be recognised as dark spots. The two larger dark spots at top and right are cross sections of the main axons which run into the lip nerves. In *b*, the largest dark spot is the main axon of the serotonin cell in the ipsilateral buccal ganglion cut in transverse section. Branches of this axon (one fine branch arrowed) terminate within the buccal ganglion neuropile, which is in the middle of the photograph. Scale bars represent 25 μm .

Fig. 2 Diagram of the processes of a right giant serotonin neurone injected with tritium-labelled serotonin. The cerebral and buccal ganglia are joined by connective nerve trunks (CBC). The position of identified neurones in each buccal ganglion which receive synaptic input from the serotonin neurone is indicated with an arrow. Axon branches pass close to, and there are numerous small terminal processes in the immediate vicinity of, these follower neurones. Each cerebro-buccal connective contains two axon processes of the serotonin cell which run close together within the connective. Axon processes pass into the nerves supplying the buccal mass and into the pharyngeal nerves (P), which supply the muscles which control feeding. Two or three separate axon processes of the serotonin neurone pass into each external lip nerve (ELN). The axon processes within these nerves run to muscles in the mouth of the animal. It thus seems that all the peripheral axon branches of the serotonin neurone are somehow associated with feeding. The size and depth of the axon processes observed in transverse sections of each nerve are relatively constant. This is indicated by the diagrams of the cross sections of the nerve trunks, where each circle beside a particular trunk illustrates the situation in a different ^3H -serotonin injected preparation. The processes are located close to the periphery of the CBC and ELN but centrally within the internal lip nerve (ILN). The axon processes of the serotonin neurone are not round in cross section, but have infoldings which vary in shape from section to section. The many small branches within the right and also possibly the left, cerebral ganglia, are thought to be dendrites receiving synaptic input. The areas indicated by *a* and *b* are illustrated in Fig. 1.

cells partly recovered after injection (the resting potential returned to about -20 to -40 mV). The preparation was left for 10–15 h at 4°C before processing for autoradiography.

For light microscope autoradiography, the tissue was fixed for 2 h in 2.5% glutaraldehyde solution, dehydrated in a series of ethanol solutions and embedded in wax. Radioactivity was monitored in the histological solutions. Little if any wash out of the isotope could be detected, that is, less than 100 c.p.m. ml^{-1} of any histological solution. Serial sections (8 μm) were prepared and mounted on glass slides. The sections were covered with Kodak AR 10 stripping film and developed in Kodak D 19 after storage in the dark for

two weeks. For electron microscope autoradiography, tissue was fixed in glutaraldehyde and osmium solutions and embedded in Epon. Thin sections were covered with a monolayer of Ilford L4 emulsion by a loop technique⁸, exposed for three weeks, and subsequently developed in Kodak Mikrodol-X.

Similar results were obtained in all of the experiments. Five light microscope experiments (three left and one right serotonin neurones were injected with ^3H -serotonin and one right neurone was injected with ^3H -5-hydroxytryptophan) and two electron microscope experiments (two left serotonin neurones injected with ^3H -serotonin) were made. The radioactive material was sufficiently well bound to withstand the histological treatment and it was readily detected in the autoradiograms (Figs 1 and 3). Apart from the region in the immediate vicinity of the perikaryon of the serotonin neurone, where there was some spillage and binding of the isotope to connective tissue, it appeared that all the radioactivity detected in the autoradiograms was strictly located within the giant serotonin neurone. The main axons could be easily followed in serial sections with the light microscope and fine terminal branches could be traced at a distance of 1 cm or more from the perikaryon, for example in the buccal ganglia (Fig. 1b), where there was a complete lack of silver grains over the outer connective tissue capsule. The processes of the right serotonin neurone traced by this method are shown diagrammatically in Fig. 2. The processes of the left serotonin neurone form a pattern which is the mirror image of the right neurone.

The results of the light microscope autoradiography showed that axon processes of each giant serotonin neurone pass to the region of the buccal ganglia where the identified follower neurones are located. In these regions many fine terminal branches were seen. In some sections, silver grains were seen directly adjacent to the axon hillocks of the identified follower neurones. This morphological evidence therefore agrees with the electrophysiological results suggesting the presence of monosynaptic connections of the serotonin neurones and these follower neurones. The distribution of fine branches in the neuropile of each buccal ganglion was very similar to that observed after uptake of exogenous ^3H -serotonin by the isolated buccal ganglia⁹.

The pattern of processes was remarkably similar in each preparation. The presence of two or more axon processes running parallel for considerable distances along some nerve trunks is an interesting, but so far unexplained phenomenon, also noted by other workers¹⁰. There was a constancy in the relative sizes of the different processes within a particular nerve trunk and their positioning with respect to the centre or periphery of the particular nerve trunk (see Fig. 2). It is apparent that there is an extensive overlapping of the fields of innervation of each giant serotonin cell, as was suggested by electrophysiological experiments^{3,4}.

When a cerebro-buccal connective or external lip nerve was ligatured, there was a build up of radioactivity on the side of the constriction nearer the perikaryon. This was shown by an increase in density of silver grains within the axon of the serotonin cell against the ligature. This experiment suggested that the labelled serotonin was actively transported along the axons. The minimum rate of movement of the isotopically labelled material within the serotonin cell axon was 1.0 mm h^{-1} .

By electron microscope autoradiography it was possible to study the axons of the serotonin neurone within the cerebro-buccal connectives and some of its terminal processes within the neuropile of the buccal ganglia (Fig. 3). The identification of groups of silver grains over processes of the serotonin neurone was comparatively easy, because after the relatively short time periods of radiographic exposure employed, background silver grains were almost completely absent. Identification of processes from the serotonin neurone with the electron microscope was also

Fig. 3 Electron microscope autoradiograms of cross sections of the cerebro-buccal connective and buccal ganglia showing axons of a serotonin neurone injected with tritium-labelled serotonin. In *a* the silver grains are marked with white arrows for clarity; the black arrows point to groups of dense-cored vesicles. In *b* the black arrow points to a silver grain which overlies a dense-cored vesicle. The silver grain to the right in *b*, and also the silver grain second from top in *a*, seem to be associated with larger electron-dense structures. *c*, Presumed terminal process of an injected serotonin neurone within the neuropile of a buccal ganglion. The arrows point to dense-cored vesicles. The star marks a silver grain which does not obviously overlie the same structure as the other silver grains, although it is possible that this is the case, and that the labelled ending is shown at two levels within the same section. Scale bars represent *a*, μm ; *b*, $0.5 \mu\text{m}$; *c*, $0.5 \mu\text{m}$.

aided by comparison with adjacent thicker tissue sections processed for light microscope autoradiography.

All the labelled axon processes contained vesicles with electron-dense cores (Fig. 3). These vesicles had an average diameter of 100 nm, and were morphologically identical to those which are thought to sequester serotonin in the perikaryon of the serotonin neurone¹¹ and those seen in a small proportion of nerve endings in the buccal ganglia which selectively accumulate exogenous tritium-labelled serotonin⁸. Some silver grains overlay such vesicles (Figs 3b and c).

None of the terminal processes observed resembled classical synapses in containing membrane thickenings, however 'typical' synapses are only rarely seen in the central nervous system of this animal¹¹. Because the fine terminal processes of the serotonin neurone in the neuropile regions contain many vesicles (Fig. 3c), they probably represent, or are close to, the release sites of the transmitter.

The results suggest that the technique of injecting tritiated 'transmitter', or a readily metabolised precursor, may be of general value in mapping the axons, and locating and studying the structure of the presynaptic terminals of individual neurones of known transmitter type. The technique is similar to that of injecting radioactive amino acids before autoradiography, which has been shown to be valuable in studying the anatomy of, and axonal transport within, the dendrites of single mammalian spinal motor neurones^{12,13}. In the latter situation, however, there was evidence for a transfer of radioactivity between glia and other neurones, and it was not established that any of the proteins presumed to be labelled after incorporation of the radioactive amino acids might have been destined for the presynaptic terminals^{12,13}. On the other hand, it might be expected that injected transmitter will be treated as natural transmitter and transported to and concentrated within presynaptic terminals. (Some experimental results, not described here, obtained after the injection of leucine into identified snail neurones support this view). Further, the results show that no noticeable damage is caused by the iontophoresis of tritium labelled serotonin to the fine structure of the neurone. This is not the case with other intraneuronal staining techniques^{5,6,14,15}. Finally, the results show for the first time that the presynaptic endings of a specified neurone of known transmitter type can be studied in direct relation to its perikaryon.

Calcium ionophore X-537A increases spontaneous and phasic quantal release of acetylcholine at frog neuromuscular junction

TRANSMITTER release from nerve endings is believed to be triggered by the influx of Ca^{2+} , which is thought to enter the terminal as a result of an increase in conductance produced by the action potential¹. At the neuromuscular junction the evidence for the role of Ca^{2+} is largely indirect, based on changes in endplate potential (e.p.p.) amplitude following variations in $[\text{Ca}^{2+}]_0$. Miledi² showed that microinjection of Ca^{2+} into the presynaptic terminal at the synapse of the squid giant axon causes a brief period of enhanced quantal release. Ca^{2+} also affects the rate of spontaneous quantal release at the neuromuscular junction; miniature end-plate potential (m.e.p.p.) frequencies are very low in solutions with reduced Ca^{2+} (ref. 3-5). The mode of action of Ca^{2+} within the terminal remains largely a matter of speculation. Now a new tool has become available: an ionophore, X-537A, that transfers both univalent and divalent cations across lipid bilayers and cell membranes⁶⁻¹⁰. Using X-537A it may be possible to change intracellular Ca^{2+} levels while observing changes in quantal release. The ionophore might also be used to transfer other divalent metal ions into the terminal, to see how effective they are compared with Ca^{2+} .

Using conventional methods, e.p.p.s and m.e.p.p.s were recorded intracellularly from the sartorius and cutaneous pectoris muscles of the frog *Rana pipiens*. Initial experiments were performed in our usual Ringer, based on an analysis of plasma¹¹, containing (mM): NaCl, 100; KCl, 2.0; CaCl_2 , 2.5; MgCl_2 , 3.0, and Tris-maleate buffer (pH 7.4), 8.0. In later experiments the Ringer was modified to contain only one metal chloride salt; in each case the concentration of the divalent ion is specified. All experiments were performed at 17° C. To record e.p.p.s, 3×10^{-6} g ml⁻¹ d-tubocurarine

Fig. 1 The effect of X-537A on e.p.p. amplitude in a sartorius muscle. The sciatic nerve was stimulated supramaximally once every 2.5 s. The shaded region indicates the period during which the solution was being changed at a rate of 10 ml min⁻¹. The volume of the bath was about 5 ml. The numbers show the concentration of X-537A in μM .

Fig. 2 The effect of a series of increasing concentrations of X-537A, on the frequency of m.e.p.p.s. recorded from the sartorius muscle in 2.5 mM Ca^{2+} -Ringer. The width of each bar represents the period during which m.e.p.p. count was made. The shaded regions indicate the periods during which a solution change took place. The figures across the top show the X-537A concentration.

chloride was added to the Ringer. To increase the amplitude of m.e.p.p.s 1×10^{-6} g ml^{-1} neostigmine bromide was added.

The effect of X-537A on e.p.p. amplitude in 2.5 mM Ca^{2+} -Ringer is shown in Fig. 1. In Ringer the mean amplitude was 3.9 ± 0.3 mV (s.d., $n=103$). As Ringer containing 15 μM X-537A flowed into the chamber, the amplitude of the e.p.p. began gradually to increase. Within 205 s of the completion of the solution change, it reached a maximum of 26.9 mV. Then it declined precipitately and disappeared abruptly. In two other experiments similar responses were observed in 10 and 15 μM X-537A, though in these examples it took somewhat longer to reach a maximum e.p.p. and the increase was less marked. (10 μM X-537A: control 1.6 ± 0.4 mV ($n=101$) to a maximum of 5.5 mV. 15 μM X-537A: 1.1 ± 0.3 mV ($n=102$) to a maximum of 4.4 mV). Again the e.p.p.s disappeared abruptly within 4 min of reaching the maximum amplitude. Similar results were obtained from preparations in which transmission was blocked by increasing the Mg^{2+} concentration to 20 mM. The X-537A does not cause an increase in m.e.p.p. amplitude; in fact it may produce a decrease. For example, the mean m.e.p.p. amplitude in 2.5 mM Ca^{2+} -Ringer was 2.5 ± 0.85 mV (s.d., $n=50$; corrected to a standard membrane potential of 90 mV¹²). After 3 min in 15 μM X-537A the m.e.p.p. amplitude was 1.4 ± 0.35 mV ($n=50$). Another experiment gave a similar result. This means that the increase in e.p.p. amplitude produced by the drug must be caused by an increased release of acetylcholine from the motor nerve.

The effects of increasingly larger concentrations of X-537A on the frequency of m.e.p.p.s recorded in 2.5 mM Ca^{2+} -Ringer are shown in Fig. 2. X-537A at 5 or 10 μM did not elicit a change. During exposure to 15 μM there was a brief acceleration of m.e.p.p. frequency, lasting only about 90 s. With 20 μM there was a massive increase, followed by a decline to extremely low levels. In 2.5 mM Ca^{2+} , 3.0 mM Mg^{2+} -Ringer, 10 μM X-537A produced a notable increase in four of seven trials; 20 μM produced a notable increase in five of seven experiments. It is not uncommon for concentrations lower than those required for massive release to elicit a slight, transitory increase in m.e.p.p. frequency.

Figure 3 shows that the addition of X-537A to a Ringer solution containing no divalent cation does not change the m.e.p.p. frequency. The subsequent addition of 2.5 mM Ca^{2+} leads to a marked, transitory increase in m.e.p.p. rate. (In control experiments, the addition of 2.5 mM Ca^{2+} to a preparation in Ca^{2+} -free Ringer leads to about a two-fold, sus-

tained increase in m.e.p.p. frequency.)

Calcium is not the only effective metal. For example, the addition of 1.5 μM X-537A to a preparation soaked in 2.5 mM Ba^{2+} -Ringer led to a transitory increase in m.e.p.p. frequency which lasted for 55 min, the maximum frequency was 128 times the control level.

Fig. 3 The effects of Ca^{2+} on the response to X-537A. The cutaneous pectoris muscle was first soaked for 24 h in the refrigerator in a Ringer made without divalent cations but containing 1.0 mM MgEGTA. Then, as shown in the figure, the muscle was soaked in the same Ringer containing 25 μM X-537A during the period indicated as 25. The solution contained 25 μM X-537A and 2.5 mM Ca^{2+} but no MgEGTA during the period indicated as 25 (Ca).

A rough estimate of the relative effectiveness of different metals in accelerating spontaneous quantal release in the presence of X-537A can be drawn from Fig. 4. The apparent sequence is: $\text{Ba}^{2+} > \text{Sr}^{2+} > \text{Ca}^{2+} > \text{Mn}^{2+} \approx \text{Co}^{2+} \approx \text{Ni}^{2+} > \text{Mg}^{2+}$. For those metals for which both physiological and chemical data are available, the effectiveness in promoting spontaneous quantal release seems to parallel the ability of X-537A to carry the metal into a hydrophobic layer⁶.

Fig. 4 The relative effectiveness of different metals in increasing m.e.p.p. frequency in the presence of X-537A. In each experiment, the muscle was first soaked in Ringer containing 2.5 mM of the indicated metal. The m.e.p.p. frequency in this solution is (f_{cont}). The maximum m.e.p.p. frequency in the presence of the indicated concentration of X-537A is (f_{exp}). The muscles were usually soaked for two hours in the metal Ringer before observations were begun. Values obtained from the same endplate are connected by lines.

When the preparation is exposed to effective concentrations of X-537A and a metal, the period of enhanced m.e.p.p. frequency lasts for 5–55 min. After the period of rapid release: (1) m.e.p.p.s are rarely seen; (2) in Ca^{2+} -Ringer, nerve stimulation does not elicit an e.p.p.; (3) tetanic nerve stimulation does not produce the usual increase in m.e.p.p. frequency; (4) a second application of X-537A does not produce a second increase in m.e.p.p. frequency. The reasons for the disappearance of m.e.p.p.s and for the abrupt failure of transmission are still uncertain. The compound action potential in the sciatic nerve is not affected by 25 μM X-537A, but we have not yet tested conduction in the terminals immediately above the end-plate.

In conclusion the Ca^{2+} -transporting antibiotic, X-537A, together with a divalent metal ion can elicit a substantial, transitory increase in m.e.p.p. frequency and in acetylcholine release elicited by nerve stimulation. The steep dose-effect curve suggests that the relation between intracellular metal concentration and rate of release is not linear. This finding may bear on the well known nonlinear relation between $(\text{Ca}^{2+})_i$ and quantal release from stimulated terminals^{13–15}. Once brought into the terminal by the ionophore, or by nerve stimulation¹⁶ each of several divalent metals increases the frequency of quantal release.

This study was supported by a grant from the National Institute of Neurological Diseases and Stroke. The X-537A was a gift from Hoffman-La Roche.

Arginase affects lactogenesis through its influence on the biosynthesis of spermidine

THE activity of arginase in mammary gland increases markedly during lactation^{1–3}. Since lactating mammary gland, unlike liver, lacks other enzymes of the urea cycle³, the function of arginase in this gland is somewhat restricted. Results of earlier studies^{3,4} have suggested that the enzyme is involved in proline formation, in concert with ornithine aminotransferase, for increased synthesis of milk protein.

Another possible role for arginase is participation in the biosynthesis of spermidine. This possibility appears particularly attractive because the concentration of spermidine increases markedly in lactating tissue, as do the activities of

ornithine decarboxylase and S-adenosyl-L-methionine decarboxylase⁵. In the presence of the latter two enzymes, ornithine formed by arginase can be converted to spermidine through putrescine⁶. Moreover, recent studies⁷ on the development of mammary gland *in vitro* have demonstrated that spermidine, together with insulin and prolactin, produces a marked increase in the synthesis of milk proteins, which is similar to that produced by the combination of insulin, glucocorticoid and prolactin. The involvement of spermidine in milk protein formation is further supported by the observation⁷ that the combination of these three hormones enhances the cellular concentration of spermidine before the accelerated synthesis of the milk proteins, casein and α -lactalbumin.

We have investigated the mechanism whereby the interplay of the hormones stimulates spermidine formation during mammary development. The data demonstrate that prolactin, in the presence of insulin, increases the activity of arginase in mammary epithelium. It appears that arginase may have a crucial function in milk protein synthesis by participating in the biosynthesis of spermidine.

The hormonal regulation of arginase activity was examined by culturing mouse mammary explants in a chemically defined medium containing several combinations of insulin, hydrocortisone and prolactin (Table 1). These hormones effect morphological and biochemical changes associated with mammary gland development⁸. Although mammary gland is primarily composed of epithelial cells and a large mass of fat cells during pregnancy, the activity of arginase in the gland was almost completely recovered in the homogenate of isolated epithelial cells⁹. After 3 d of culture, the initial level of arginase activity was maintained in the presence of insulin. Hydrocortisone by itself, or prolactin alone, or the combination of the two could not effectively maintain the initial level, and the enzyme activity decreased markedly as it did in the absence of any added hormones. In the presence of insulin, prolactin produced a

Table 1 Effect of various combinations of insulin, hydrocortisone, and prolactin on the activity of arginase in mammary explants in culture

Culture conditions	Arginase activity (μg urea formed per 10 min per mg wet wt tissue)
Single incubation	
Uncultured control	1.02 \pm 0.05
No hormone	0.40 \pm 0.08
Insulin	1.00 \pm 0.07
Hydrocortisone	0.38 \pm 0.04
Prolactin	0.41 \pm 0.04
Hydrocortisone + prolactin	0.38 \pm 0.05
Insulin + prolactin	3.20 \pm 0.08*
Insulin + hydrocortisone	1.28 \pm 0.04*
Double incubation	
Control	1.24 \pm 0.08
Insulin	1.31 \pm 0.05
Prolactin	0.47 \pm 0.04
Insulin + hydrocortisone	1.40 \pm 0.09
Insulin + prolactin	3.10 \pm 0.08*
Insulin + hydrocortisone + prolactin	4.43 \pm 0.07*

Mammary explants from midpregnant C3H/HeN mice were cultured in Medium 199 (Gibco) containing the indicated combination of hormones as described previously¹⁰. The final concentration of hormones was 5 μg ml⁻¹ for insulin and prolactin, and 0.5 μg ml⁻¹ for hydrocortisone. Single incubation was carried out for 72 h. Double incubation was carried out by first culturing mammary explants in insulin-containing medium for 72 h and then transferring explants to medium containing the indicated combination of hormones. After transfer the explants were cultured for another 72 h. Control in the double incubation system refers to explants cultured with insulin for the initial 72 h.

The activity of arginase was determined by measuring the formation of urea from arginine as described earlier¹¹. Each value represents the mean \pm s.e.m. of six separate determinations on three separate cultures.

* The increase is significant over control ($P < 0.01$).

Table 2 Effect of various culture conditions on α -lactalbumin activity in mammary gland explants

Culture conditions	α -Lactalbumin activity (pmol lactose formed per 30 min per mg wet wt tissue)
Uncultured control	20 \pm 5
Three hormones in regular M199	90 \pm 7
Three hormones in arginine-deficient M199	32 \pm 4
Three hormones + L-ornithine in arginine-deficient M199	95 \pm 6
Three hormones + putrescine in arginine-deficient M199	91 \pm 6
Three hormones + spermidine in arginine-deficient M199	85 \pm 5
Three hormones + proline in arginine-deficient M199	30 \pm 5
Three hormones + lysine in arginine-deficient M199	22 \pm 4
Three hormones + spermine in arginine-deficient M199	10 \pm 4

Mammary explants from midpregnant C3H/HeN mice were cultured for 48 h in the presence of insulin, hydrocortisone and human placental lactogen. The final hormone concentration was 5 μ g ml⁻¹ for insulin and hydrocortisone, and 1 μ g ml⁻¹ for human placental lactogen. Human placental lactogen was previously shown to be as effective as prolactin in stimulating milk protein synthesis in mammary explants¹⁹. Arginine-deficient Medium 199 contained 0.2 mM L-arginine, whereas regular Medium 199 contained 4 mM L-arginine. The final concentration of other added amino acids was 0.05 mM L-ornithine, 4 mM L-proline, and 5 mM L-lysine. The final concentration of putrescine, spermidine and spermine was 4 mM.

The activity of α -lactalbumin was determined by measuring the formation of lactose from uridine-diphospho-¹⁴C-galactose (290–300 mCi mmol⁻¹, New England Nuclear Corp.) and glucose as described previously¹⁹. Each value represents the mean \pm s.e.m. of four separate determinations on two cultures.

large increase in the enzyme activity, whereas hydrocortisone consistently produced a slight increase.

Insulin stimulates cell proliferation in mammary epithelium during the first 2 d of culture, but by the third to fourth day the proliferative activity disappears¹⁰. These non-proliferative cells are still viable since they synthesise milk proteins in response to insulin, glucocorticoid and prolactin^{11,13}. Table 1 shows that addition of prolactin to the culture of such cells also resulted in increased arginase activity. The stimulatory effect of prolactin was enhanced by hydrocortisone although the steroid alone, or in combination with insulin, produced little increase in arginase activity in post-mitotic cells. It is clear that the effect of prolactin again required the presence of insulin, since no stimulation occurred when insulin was omitted during the second incubation. These results indicate that stimulation of arginase activity by prolactin is not a consequence of the increase in the number of mammary epithelial cells since proliferation of mammary epithelium was essentially completed when prolactin was added.

We next assessed the possibility that arginase participates in milk protein synthesis by supplying ornithine for the formation of spermidine (Table 2). When mammary explants were cultured in medium in which the concentration of arginine was reduced from 4 mM to 0.2 mM, the triple hormone combination produced very little increase in the synthesis of α -lactalbumin. However, addition of ornithine, the product formed by arginase, to such a medium restored the increase in α -lactalbumin. Addition of the polyamines, putrescine and spermidine, was also effective, whereas another polyamine, spermine, and amino acids such as proline and lysine did not effect an increase in α -lactalbumin. The effect of arginine deprivation is specific in the sense that in experiments where the concentration of other amino acids, such as leucine, was similarly reduced in the culture medium the three hormones produced an increase in α -lactalbumin similar to that observed in the regular medium 199 (not shown). These results can best be explained by the possibility that arginine may be converted, through ornithine and putrescine, to spermidine, which is required for milk protein synthesis^{7,14}. Preliminary studies indicate that ³H-arginine is indeed converted to ³H-spermidine and that prolactin stimulates this conversion by enhancing the activity of arginase (our unpublished

results). These results strongly suggest that arginase plays an important role in the biosynthesis of spermidine. Earlier studies^{14,15} on cultured mammary explants showed that insulin stimulates the activity of ornithine decarboxylase and that glucocorticoid increases the activity of S-adenosyl-L-methionine decarboxylase. Thus it appears that insulin, glucocorticoid, and prolactin interact to stimulate a group of enzymes which are involved in the biosynthesis of spermidine during the development of mammary epithelium. In view of the observation^{7,14} that spermidine is necessary for milk protein synthesis, such interaction may represent a fundamental mechanism for the regulation of lactogenesis by these hormones.

Finally, it should be emphasised that our studies *in vitro* do not exclude a possible role of arginase for proline formation, as suggested earlier³. It is possible that in addition to a role in spermidine formation, arginase may also participate in proline synthesis in intact animals where the proline supply may not be abundant.

We thank Dr Y. J. Topper for encouragement and support throughout this investigation.

Cytosol-binding protein of thyroxine and triiodothyronine in human and rat kidney tissue

DURING the past few years, it has become increasingly apparent that nonpeptide hormone action in the respective target organs occurs in the nucleus. This was first shown for steroid hormones^{1–4} and more recently for thyroid hormones⁵. Specific nuclear acceptor molecules for hormones have been shown in target tissues, associated with nuclear proteins^{6–8}. The question arises whether hormone molecules, on their way to the nuclear binding sites, traverse the cytoplasm in a more or less random fashion or whether they are bound by specific cytoplasmic receptor molecules.

Fig. 1 Comparison of radioactive scans of human serum and human renal cell binding proteins. Electrophoresis was done in glycine-acetate, pH 8.6. The label is $^{125}\text{I}-\text{T}_4$.

Accordingly we have sought specific cytoplasmic proteins that bind thyroid hormones and are distinctly different from the serum protein carriers such as thyroxine-binding α -globulin (TBG), thyroxine-binding prealbumin (TBPA) and albumin, the major carriers of thyroid hormones in the circulations of rats as well as humans. In particle-free cytosol preparations from rat kidneys we have found four separate protein peaks, three of which bind both thyroxine (T_4) and triiodothyronine (T_3). One peak seems to bind T_3 only. Thus, the cytoplasmic transport of thyroid hormones seems to depend on receptor molecules.

Male Sprague-Dawley rats weighing in excess of 250 g were used. Cytosol was prepared from perfused rat kidneys and livers. The aorta was cannulated and the kidneys perfused *in situ* for 20–30 min with ice-cold isotonic saline solution until the venous effluent was crystal clear. Subsequent protein determinations by the Oyama-Eagle modification⁹ of the Lowry method¹⁰ confirmed the absence of appreciable protein in the effluent irrigation solution. The kidneys were removed and homogenised in three volumes of saline solution in an all glass homogeniser. In some cases the homogenate was spun at 800g to obtain a supernatant free of nuclei and gross membrane fragments. The supernatant or the homogenate, packed in ice, was sonicated for 3 min with a Savant Instrument Model 1000 Insonator. The sonicated material was centrifuged for 1 h at 105,000g in a Beckman L3-50 ultracentrifuge. The temperature throughout this procedure was 0°–4°C. After centrifugation the supernatant was decanted and stored at –20°C until used.

The cytosol proteins were labelled with $^{125}\text{I}-\text{T}_3$ or with $^{131}\text{I}-\text{T}_4$ (Industrial Nuclear) and subjected to paper electrophoresis. The electrophoretic systems were 0.2 M glycine-acetate, pH 8.6 (refs 11, 12), 0.125 M sodium borate buffer, pH 10.0, or 0.05 M sodium glycinate buffer, pH 10.0. The paper strips were dried after electrophoresis and scanned with a Nuclear-Chicago Actigraph III (Model 1004) strip scanner. In case of dual labelling, the strips were scanned rapidly and the area containing radioactivity was cut into 0.5 cm segments, which were then counted in a Packard Auto-Gamma spectrometer. Cultures of human kidney and liver cells were purchased from Microbiological Associates and treated as described earlier¹³.

The total protein content of the effluent perfusate was less than 2 mg ml⁻¹ after 20 ml of effluent had been collected, and less than 1 mg ml⁻¹ after 150 ml had been collected, which usually required 20–30 min of perfusion. The liver perfused through the portal vein exhibited blanching, but effluent fluid was not analysed.

It was not unexpected therefore, that cytosol preparations subjected to electrophoresis showed no peak with the mobility of serum TBG. In all cases, cytosol-binding proteins (CBP) were readily evident on scanning of dried paper electrophoretic strips; the scanning was done before staining with bromphenol blue to avoid elution of the tracer.

The dialysis of the cytosol against at least 100 volumes of buffer or saline solution overnight before electrophoresis revealed retention of more than 60% of the radioactivity by the cytosol solution in the dialysis bag, signifying unequivocal protein binding.

Gel filtration studies on Sephadex G-200 showed a protein peak of radioactivity compatible with a molecular weight of about 70,000. To investigate the existence of cytosol binders in human kidney tissue, similar electrophoretic studies were carried out on sonicated human renal cells which had been incubated with $^{125}\text{I}-\text{T}_4$ as previously reported¹³. A typical scan is illustrated in Fig. 1, which shows 'pre-TBG' and 'post-TBG' peaks, so designated because of their mobility, as well as origin radioactivity. The low level of radioactivity in human renal cell sonicates reflected the tracer amounts of hormone added to the cell cultures, approximately 2×10^{-8} M T_4 .

The amount of origin radioactivity in different human and rat cell studies was quite variable, occasionally absent, and not clearly associated with any obvious experimental detail.

Experiments were also performed on perfused rat liver cytosol as well as human liver cells (Chang liver) grown in culture¹³, with findings of cytosol binding proteins in all cases.

As Fig. 2 shows, labelled T_3 was apparently bound by different cytosol-binding proteins than T_4 , as illustrated in electrophoretic strips run simultaneously.

Fig. 2. Rat renal cytosol binding proteins for T_4 and T_3 . Electrophoresis was done in glycine-acetate, pH 8.6.

Since it could be argued that the different ligands could conceivably cause slightly different electrophoretic mobilities, experiments were carried out in which both labelled hormones as $^{125}\text{I}-\text{T}_3$ and $^{131}\text{I}-\text{T}_4$ were added to the same rat renal cytosol preparation. A peak with greatest anionic mobility was found to bind T_3 but not T_4 , even with increments of nonradioactive T_4 as high as 20 mg per 100 ml (2.6×10^{-7} M) as illustrated in Fig. 3. Whereas the glycine-acetate system at pH 8.6 used in the foregoing studies provided reasonable separation of peaks, we found that the sodium borate and sodium glycinate buffer systems at pH 10.0 provided much more rapid migration and greater separation of cytosol binding proteins (although these alkaline buffers are less satisfactory for study of serum protein carriers).

Fig. 3 Rat renal cytosol binding proteins for T_4 and T_3 . Cytosol contained both $^{125}\text{I}-\text{T}_3$ and $^{131}\text{I}-\text{T}_4$. Electrophoresis was done in sodium glycinate buffer, pH 10.0. The radioactive scan above reflects mainly ^{131}I , and ^{125}I to a lesser degree. In the histogram below with discrimination between the labels, in addition to origin radioactivity, the labelled T_3 is distributed in four peaks, appropriately numbered, with 4, which has moved farthest toward the anode at the left, clearly showing T_3 , but no appreciable T_4 radioactivity. In contrast, the other peaks bound both radioactive hormones. In the run illustrated, the concentration of T_3 added was $0.16 \mu\text{g}$ per 100 ml (2.4×10^{-9} M), while the T_4 was $11 \mu\text{g}$ per 100 ml (1.4×10^{-7} M). Similar results, that is, peak 4 showing T_3 but not T_4 radioactivity were also seen with the same T_3 concentration, but T_4 concentrations of 1.1, 6.1, and also $21.1 \mu\text{g}$ per 100 ml (1.4×10^{-8} M, 7.9×10^{-8} M and 2.7×10^{-7} M).

The basic finding is the demonstration of binding of thyroid hormones by cytosol with retention of the ligand hormones after overnight dialysis. The demonstration of electrophoretic peaks suggests that it may become possible to isolate specific cytosol binding proteins and determine their binding constants by equilibrium dialysis and other methods. The findings are in general agreement with the preliminary descriptions of cytosol binding proteins by others¹⁴⁻¹⁷.

The use of strongly alkaline (pH 10.0) buffers represents a novel technical approach, in that it enhanced the sensitivity of ordinary paper electrophoresis with conventional rather than 'reverse' or countercurrent flow¹⁸. Since the overall picture is not different from those runs with lower pH, it is reasonable to assume that the only effect of the high pH was increased separation.

Hormone action at the molecular level seems to involve the interaction between the hormone and the nonhistone or acid soluble protein associated with nuclear chromatin, when small molecule (nonpeptide) hormones are considered. The evidence amassed during the past decade includes more evidence for the

action of the steroid hormones than for the thyroid hormones. Thus numerous studies have dealt with the sex steroids^{19,20} cortisol²¹ and aldosterone^{22,23}. The thyroid hormones, on the other hand, have been considered to have a primary action on the cell nucleus since the demonstration of nuclear localisation of labelled thyroid hormone by Siegal and Tobias²⁴ in cultured human renal epithelial cells. Further evidence concerning nuclear binding of the thyroid hormones has been found in our laboratory, in which nuclear uptake *in vitro* has been shown, and further details have been reported by others⁵⁻⁷. Since there is also evidence of mitochondrial mediation of thyroid hormone action²⁵⁻²⁸, it is interesting that we have found mitochondrial protein binding of both T_4 and T_3 , in studies now in progress.

Aryl hydrocarbon (benzo(a)pyrene) hydroxylase in human peripheral blood monocytes

MICROSOMAL mixed-function oxygenases metabolise a variety of exogenous compounds, including drugs, pesticides and carcinogens, as well as endogenous substances such as steroids^{1,2}. One oxygenase, aryl hydrocarbon hydroxylase (AHH), is important in both the detoxification of some carcinogenic polycyclic hydrocarbons and the activation of others to more carcinogenic forms¹⁻⁴. Hydroxylase activity and cytochrome P-450 have been found in various tissues of animals^{1,2} and man⁵⁻¹². AHH activity increases in many tissues after treatment with polycyclic hydrocarbons. In certain inbred mouse strains this increase appears to be regulated by a single autosomal dominant gene¹³, and a correlation between enzyme levels and susceptibility to methylcholanthrene-induced tumorigenesis has been reported¹⁴. Data obtained by Shaw and his colleagues point to genetic regulation of AHH in human populations¹⁵.

With the exception of peripheral blood lymphocytes, which must be stimulated with mitogens before assay, none of the human tissues in which AHH has been detected can be obtained readily for clinical and epidemiological study. Detection of AHH in macrophages of the human lung¹⁰, rat liver¹⁶ and guinea pig peritoneum¹⁷ suggested that monocytes might also contain the enzyme. We report here that AHH is present in monocytes from human peripheral blood. This observation may facilitate studies in human populations relating hydroxylase activity and the metabolism of chemical carcinogens.

Mononuclear leukocytes were obtained from heparinised human blood by the method of Boyum¹⁸. At least 99% of the cells isolated were mononuclear and excluded trypan blue. After incubation in cell culture for 24 h, the leukocytes were treated with medium that either contained or lacked the polycyclic hydrocarbon benz(a)anthracene (1 $\mu\text{g ml}^{-1}$). After incubation for a further 17 h, the culture medium was removed and the surface of the plastic culture dish was rinsed with Dulbecco's phosphate-buffered saline. The adherent cell population was more than 95% viable and contained 98% monocytes, judged by cellular morphology and by the ability of the cells to phagocytose 1 μm latex spheres (Dow) suspended in Eagle's minimum essential medium containing 10% pooled human AB serum. An average of 46×10^6 monocytes was obtained from 500 ml of heparinised blood. Treatment with benz(a)anthracene did not affect the yield, viability or differential cell count of these preparations. Monocytes were assayed for AHH activity by the method of Nebert and Gelboin¹⁹ as modified by Kellerman *et al.*¹⁵.

AHH is present in human peripheral blood monocytes and its activity is increased following treatment with benz(a)anthracene (Table 1). In twelve different donors, AHH activity ranged from 0.3 to 1.4 units per 10^6 cells and increased 4 to 33-fold after incubation with benz(a)anthracene. The activity of replicate samples from a single monocyte pool varied by less than 5%. AHH from human peripheral blood monocytes has properties which are typical of the microsomal mixed-function oxygenases (Table 2), that is, a requirement for NADPH and inhibition by carbon monoxide^{11,18}. In addition, hydroxylase activity is inhibited by 7, 8-benzoflavone, a potent inhibitor of the complex²⁰.

The presence of AHH in human peripheral blood monocytes further implicates the reticuloendothelial system in the metabolism of polycyclic hydrocarbons, suggests one explanation for the immunogenicity of these compounds and may provide a convenient assay for the study of AHH in human populations. Peripheral blood monocytes contribute to macrophage pools throughout the body and accumulate at sites of acute and chronic inflammation²¹. Circulating monocytes could provide large local concentrations of the enzyme at inflammatory foci. Cantrell *et al.*¹⁰ obtained

larger numbers of alveolar macrophages with higher hydroxylase activity per cell from the lungs of smokers than from those of nonsmokers. The infiltration of inflammatory cells evoked by cigarette smoke, by various carcinogens and by cocarcinogenic promoters might influence the local metabolism of polycyclic hydrocarbons. Reticuloendothelial cells in the liver, lung and lymphoid tissue might also participate in the detoxification or activation of certain carcinogens. Agents that stimulate or depress the reticuloendothelial system, such as BCG can modify chemical carcinogenesis²². The functional state of the reticuloendothelial system might alter the metabolic fate of carcinogenic compounds.

Table 1 Aryl hydrocarbon hydroxylase activity in human peripheral blood monocytes

	Specific activity*	
	Donor 1	Donor 2
Control	0.5	1.4
BA-treated	12.9	19.3

Monocytes were suspended in 0.85 ml of a solution (pH 7.55) containing 67.5 $\mu\text{mol KH}_2\text{PO}_4$, 66.7 $\mu\text{mol KOH}$, 4.2 $\mu\text{mol MgCl}_2$ and 25 μmol nicotinamide. A solution (100 μl) containing 0.7 mg NADH, 0.7 mg NADPH and 0.7 mg bovine serum albumin was added. The reaction was started by the addition of 100 nmol of the substrate benzo(a)pyrene, in 0.050 ml acetone. Incubations were for 20 min at 37°C under the illumination of a single 25 W red bulb. The reaction was stopped by the addition of 1.0 ml acetone and the mixture was extracted with 3.0 ml hexane. A 2.5 ml sample of the organic layer was extracted with 1.0 ml 1 N NaOH, and the fluorescence of the alkali phase was measured in an Aminco-Bowman spectrofluorometer and compared with that of a standard 3-hydroxybenzo(a)pyrene solution. The reaction was linear with respect to the time of incubation (0–20 min) and the number of monocytes that was assayed.

*Units per 10^6 cells. One unit of AHH activity catalyses in 20 min the formation of phenolic products with the fluorescence equivalent to that of 1 pmol of 3-hydroxybenzo(a)pyrene. Each assay contained $1.4\text{--}3.3 \times 10^6$ monocytes.

Table 2 Effect of assay conditions on aryl hydrocarbon hydroxylase activity from human peripheral blood monocytes

Assay system	Specific activity*
Complete	5.0
No NADPH	1.5
90% CO–10% O ₂	1.6
7.8 BF (10^{-4}M)†	2.0

Monocytes were treated with benz(a)anthracene (1 $\mu\text{g ml}^{-1}$) as outlined in the text. AHH was assayed as described in Table 1. *Units per 10^6 cells. Each assay contained 3.3×10^6 monocytes.

†7.8 benzoflavone was added in 0.010 ml dimethylsulphoxide.

Cutaneous application of polycyclic hydrocarbon carcinogens can produce immunologically specific contact hypersensitivity²³. These low molecular weight hydrocarbons probably attain immunogenicity by conjugation with host proteins. Microsomal enzymes might contribute to the formation of immunogenic conjugates by converting unreactive parent compounds to reactive intermediates able to bind covalently to cellular macromolecules. Macrophages derived from peripheral blood monocytes process macromolecular antigens for presentation to lymphocytes in a more immunogenic form²⁴. AHH within macrophages could catalyse the formation of immunogenic conjugates before antigen processing.

A recent study has attempted to relate AHH levels to the development of lung cancer in man. Kellerman *et al.*²⁵ have measured hydroxylase induction in human leukocytes after incubation with phytohaemagglutinin and pokeweed mitogen. Under these conditions the polycyclic hydrocarbon 3-methylcholanthrene induced a greater increase in hydroxylase activity in leukocytes from patients with lung cancer than in leukocytes from a control population. The requirement for mitogens in this system, however, raises the possibility that hydroxylase levels might be a function of the response of leukocytes to the mitogens rather than their response to the 3-methylcholanthrene. Treatment with mitogens is not required to measure AHH in monocytes

from human peripheral blood. Monocytes constitute 2–6% of the leukocytes in peripheral blood and absolute counts range from 1×10^5 to $6 \times 10^5 \text{ ml}^{-1}$ (ref. 26). AHH assays require at least 4×10^6 monocytes for duplicate determinations following incubation with and without a polycyclic hydrocarbon. If all monocytes could be recovered, 7–40 ml of peripheral blood would suffice. While several questions remain regarding the practicality of a monocyte assay for clinical use, including the efficiency of isolation techniques, these cells may provide a convenient source of tissue for the study of AHH in human populations.

Fig. 1 Gas chromatogram of a semen extract as methyl oximes, methyl esters and trimethyl silyl ethers. The extract was prepared by mixing the semen with four volumes of 1.5 M pyridinium acetate buffer (pH5) containing 5 mg ml⁻¹ methoxyamine hydrochloride and leaving in an ultrasonic bath for 40 min. The prostaglandins were then extracted with ether/ethyl acetate (4:1), methylated (diazomethane) and silylated (*bis*-(trimethylsilyl) acetamide). The oximation gives rise to *syn* and *anti* isomers; in the E compounds the first isomer to elute accounts for approximately 1/4 of the material derivatised⁶. The isomers are denoted by suffixes (in roman numerals) giving the order of elution. Identification of the components was by gas chromatography/mass spectrometry. The column was 1% of Dexsil 300 on chromosorb G and was programmed from 200° at 2° min⁻¹.

concentration of 40 µg ml⁻¹ (ref. 3). In a detailed study of semen PGs we have used a new approach for the measurement of the E prostaglandins, which involves protecting the unstable β-ketol system by oximation in the unextracted semen, thus ensuring minimal degradation to the A or B series. Using this technique we found that the levels of 19-hydroxy derivatives of PGA and PGB are relatively low whereas two new PGs, later identified as 11α,15,19-trihydroxy-9-keto prost-13-enoic acid (19-hydroxy PGE₁) and 11α,15,19-trihydroxy-9-keto prosta-5,13-dienoic acid (19-hydroxy PGE₂) were present at an average total concentration of 100 µg ml⁻¹. These compounds can be isolated together as the methyl ester/methyl oxime derivatives by thin layer chromatography and the individual components can be separated by gas chromatography as the methyl ester/methyl oxime/*tert*-butyl dimethyl silyl ethers⁴.

The nature of the 19-hydroxy prostaglandins E was determined by gas chromatography/mass spectrometry and thin layer chromatography. The compounds were present in gas

Fig. 2 Oxidative degradation of 19-OH PGE₂ as proof of structure. ia is 19-OH PGE₂, peroxide/permanate oxidation of the derivatised Ib followed by methylation (diazomethane) and silylation (*bis*-(trimethylsilyl) acetamide) gives ii. Oxidation of ic followed by methylation gives iii. Compound ii was also obtained by a similar oxidation of authentic PGE₂.

19-Hydroxylated E prostaglandins as the major prostaglandins of human semen

ALMOST 30 years after the initial discovery of the prostaglandins, Bergstrom *et al.*, succeeded in isolating and identifying prostaglandins (PGs) E₁, E₂, F_{1α} and F_{2α} from sources including human semen¹. It was subsequently claimed² that the 19-hydroxy derivatives of prostaglandins A and B were also present. These compounds were later found at an average

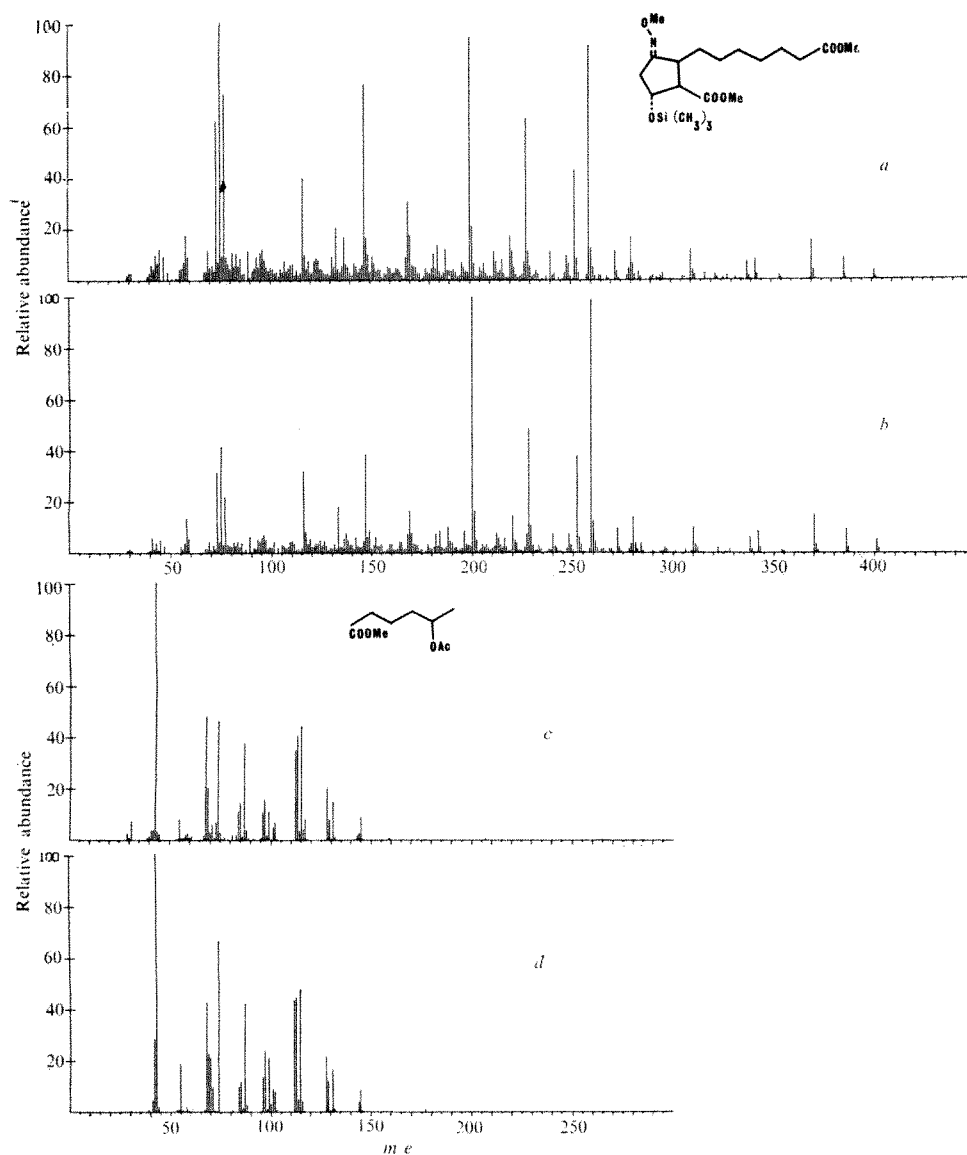

Fig. 3 Mass spectra of oxidation products of 19-OH PGE₁ (a and c) and spectra of authentic origin; (b) was obtained by the oxidation of PGE₁, and (d) was prepared by methylation, borohydride reduction in tetrahydrofuran and acetylation of 5-keto hexanoic acid.

chromatograms of semen extracts as a pair of peaks, (19-OH E₂) followed by (19-OH E₁), of approximately equal size, having retention times longer than those of E and 19-OH A prostaglandins (Fig. 1). The mass spectral evidence (Table 1) was wholly consistent with the assigned structures. The shift of 14 mass units in the molecular ion between a methyl and an ethyl oxime indicated one carbonyl group and a shift of 126 between the molecular ion of the trimethyl silyl ether derivative and that of the *tert*-butyl dimethyl silyl derivative implied three hydroxyl groups. The mass spectra of all derivatives showed many similarities to those of the E prostaglandins; particularly informative was a strong M-159 peak in the spectrum of the methyl oxime/methyl ester/TMS ether repre-

sented the loss of C₁₆ to C₂₀ of the prostaglandin molecule. This ion was particularly strong in the first isomer of the pair arising from oxidation. The loss of 159 mass units from the 19-OH compound corresponds to the loss of 71 mass units from the parent E derivative. This ion is similarly strong in the first isomer of E to elute on gas chromatography⁵. The presence of an ion of *m/e* 117 in all mass spectra of the TMS ether derivative of the 19-hydroxy compounds supported the assignment of the extra hydroxyl group to the 19 position, as this ion is characteristic of the CH (OTMSi) CH₃ group.

The identity of the 19-OH E prostaglandins was confirmed by oxidative degradation. The 19-OH E compounds were isolated as a group by TLC using the methyl ester/methyl

Ninety mass units represents loss of (-OTMSi+H), 31 mass units represents loss of -OCH₃ from methyl oximes.

oxime derivatives. These derivatives were recovered from the TLC plate and were oxidised with periodate/permanganate as described by Jacobson *et al.*⁶. This reagent hydroxylates double bonds and cleaves adjacent oxygenated functions. Thus hydroxyl groups are introduced at 13 and 14 and cleavage occurs both between C₁₃ and C₁₄ and between C₁₄ and C₁₅ (Fig. 2). To identify the fragment C₁ to C₁₃ the products of the oxidation of 1b were methylated, silylated and analysed by gas chromatography mass spectrometry. The spectrum of the expected compound (II) correlated well with the same fragment obtained by a similar oxidation of authentic PGE₁ (Fig. 3). To identify the C₁₅-C₂₀ fragment the 19-OH prostaglandins E were first acetylated (to prevent lactone formation after oxidation) and then oxidised as before. Gas chromatography mass spectrometry analysis showed the major product to be 5-acetoxy methyl hexanoate, identified by comparison with the spectrum from authentic material (Fig. 3).

The identity of these two parts of the molecule together with the mass spectral information from the intact compound conclusively identify the material present in the second gas chromatography peak as 19-OH PGE₁. The similarity in the mass spectra and the gas chromatography evidence strongly indicate that the first peak of the pair is 19-OH PGE₂.

These 19-OH prostaglandins have probably been missed before for various reasons. They are converted to the A series if left in semen (almost all 19-OH prostaglandins E had disappeared in a semen sample left at 37° C for 60 h) and they are more difficult to extract from semen than the hydroxylated A or B compounds. We have succeeded in identifying the compounds by immediate oxidation of fresh semen samples followed by extraction. We are now using this technique to establish the range of levels of these compounds in normal males and in cases of infertility.

The biological role of prostaglandins in human semen has yet to be established but it is attractive to suppose that they could be concerned with sperm migration; it has even been claimed that PGE levels are lower in the semen of infertile men³. This leads us to pursue the investigation of the biological activity and physiological significance of these exciting compounds.

We thank Dr R. V. Short for help and encouragement. Prostaglandin E₁ was a gift from Dr J. Pike of the Upjohn Company.

identified and quantitated³, and the macrophage contents of different experimental tumours were found to range from 4%–56% of the total cell population³. These cells were shown to be of host origin, most if not all being derived from circulating blood monocytes rather than by self-replication of macrophages within the tumour (Unpublished observation).

The experiments described here were designed to investigate whether the macrophage contents of a group of chemically induced rat fibrosarcomata were in any way related to their biological behaviour, and in particular to their metastatic capacity. It is possible that the number of monocytes gaining entry into a tumour is governed solely by such properties as its vasculature, or alternatively, the presence of macrophages may represent part of an immunological

Fig. 1 Effect of immunosuppression on % macrophages in tumours grown in deprived rats. *a*, Controls; *b*, rats with thoracic duct lymph drainage; *c*, sham cannulated rats; *d*, thymectomised and irradiated rats; *e*, sham thymectomised rats. The thoracic ducts of rats were cannulated and tumours implanted 1 d later. Drainage was terminated after 8–10 d when the number of lymphocytes collected over 24 h had fallen to 0.1% of the first day's yield. Sham cannulated rats underwent anaesthesia and laparotomy, but the duct was left intact. Other rats were thymectomised at 4 weeks and then received 3×300 rad whole-body irradiation (X rays) at 2 week intervals. To ensure recovery of the bone marrow, an interval of 4 weeks was allowed between the last dose of irradiation and implantation of the tumour. At this time, treated rats were able to develop normal inflammatory macrophage exudates in response to intraperitoneal oyster glycogen stimulation⁶, indicating normal monocyte production. Thymuses of sham thymectomised rats were exposed but not removed and received no irradiation. The tumour used was a benzpyrene-induced fibrosarcoma (HSBPA) which had been passaged 20–25 times in syngeneic Hooded rats. All tumours were grown intramuscularly (i.m.) in hind limbs, excised 14 d later when they were approximately 2 cm diameter, and their macrophage contents assessed by Evans' methods³. Each point represents one rat, and the horizontal bar is the mean of the group.

reaction to tumour antigens and the degree of macrophage infiltration could then be a measure of the host response.

The macrophage content of tumours grown in immunosuppressed Hooded rats was monitored. For these experiments to be interpretable, it was necessary to suppress immunity without affecting normal bone marrow function, so that the availability of monocytes would not be reduced. The procedures chosen were two methods which removed predominantly T lymphocytes: prolonged thoracic duct lymph drainage⁴ during tumour growth; and thymectomy of rats followed by repeated whole-body irradiation⁵, before tumour implantation. Both procedures caused a significant suppression in T-cell dependent immune reactivity, which was demonstrated by the fact that an allograft (Wistar rat)

Macrophage content of tumours in relation to metastatic spread and host immune reaction

THE presence of infiltrating 'histiocytic', 'mononuclear' or 'round' cells (many of which may be cells of the monocyte/macrophage series) has often been observed in histological sections of certain types of human tumours and has been claimed to indicate good prognosis^{1,2}. Evans, using a variety of functional criteria (such as adhesion to glass in the presence of trypsin and phagocytic ability) has shown that macrophages in tumour cell suspensions can be readily

tumour grew progressively in the treated rats, but was invariably rejected by normal Hooded rats.

Rats immunosuppressed by removal of T cells were inoculated with cells from a syngeneic sarcoma, HSBPA, which when grown in normal animals gives rise to tumours containing approximately 50% macrophages. Figure 1 shows that in the treated rats the mean macrophage content of the tumours was lowered considerably. The rather wide range of variation in the drained rats (Fig 1b) may be a reflection of the total number of lymphocytes removed, since the rate of drainage achieved varied in different animals. The numbers of macrophages in tumours grown in the sham cannulated group were normal, indicating that the stress of surgical trauma and confinement in restraining cages were not responsible for the observed differences. The effect of thymectomy plus irradiation was similar, but the individual values were less widely spread. This may be due to the fact that T cell removal was complete before tumour implantation, whereas in the previous group some degree of host reaction to tumour cells may have been induced before T cells were maximally depleted.

Fig. 2 Effect of immunosuppression on incidence of metastases after excision of HSBPA tumour. HSBPA tumours were grown i.m. in hind limbs of various groups of immunosuppressed rats (lymph drained, *b*, and thymectomised and irradiated, *d*) and appropriate controls (*a*, *c*, *e*) untreated rats *a*, and sham cannulated *c*, or sham thymectomised *c*, for 14 d. The tumour-bearing limbs were then amputated, and the animals kept for observation on the development of metastases for up to 30 weeks. ●, Deaths with no evidence of metastases; ○, deaths with lymph node metastases; □, deaths with lung metastases; ■, deaths with lymph node and lung metastases; △, survivors.

To investigate whether the macrophage content of a tumour can be influenced by raising the immune reactivity of the host, a Hooded rat sarcoma, MC3, was transplanted into August rats. This strain differs from the Hooded strain at minor, but not major histocompatibility loci, and will therefore allow progressive growth of Hooded rat tumours, in spite of a more pronounced host reaction to the grafts. In the syngeneic Hooded rats, the MC3 tumour grows from as few as 100 cells, invariably metastasises, and no protection to a subsequent challenge can be induced by repeated immunisation. In the 'allogeneic combination, (that is, in August rats) larger inocula of 10^6 – 10^8 tumour cells are needed and the tumour remains strictly localised. The average macrophage content of MC3 tumours grown in syngeneic hosts was 8%, whereas in August rats it was raised to 38%.

Non-specific stimulation of the reticuloendothelial system of syngeneic Hooded rats with BCG (Glaxo) before inoculation of MC3 sarcoma cells mixed with PPD reduced the incidence of spontaneous metastases from 100% to 80%, and led to a small rise in the macrophage contents of the

Table 1 Macrophage content, incidence of metastases and immunogenicity of chemically induced rat fibrosarcomata transplanted into syngeneic recipients

Tumour	Mean % macrophages (and range)	Incidence of metastases (%)	Immunogenicity
MC-3	8 (2–12)	100	< 10^3

The incidence of metastases was measured after excision of tumours which had been growing i.m. in hind limbs for 14 d. Immunogenicity was assessed as the number of cells required for tumour growth in rats which were immunised by excision of i.m. tumours 14 d previously.

tumours to between 9% and 20%. These experiments suggest that the infiltration of macrophages is associated with an effective immune response of the host to the tumour, and that the variation in the macrophage content of different tumours may be related to their immunogenicity.

Immunosuppression has been shown to facilitate metastatic spread^{7,8} and Fig. 2 shows that when the HSBPA rat fibrosarcoma was inoculated into T-cell depleted rats, the incidence of spontaneous metastases was greatly increased. From these experiments it is not possible to deduce whether the simultaneous decrease in macrophage infiltration (see Fig. 1) was causally related to the subsequent increase in metastases. A role for tumour macrophages in the control of tumour dissemination is suggested, however, by the parallel between macrophage content and the rate of spontaneous metastasis of a series of six different rat sarcomas grown in normal syngeneic recipients (Table 1).

The tendency to metastasise is also related (inversely) to the 'immunogenicity' of the tumours—this being defined as the degree of resistance to tumour challenge (expressed as the number of cells required to produce a tumour) in a suitably pre-immunised syngeneic recipient. Immunogenicity is not synonymous with antigenicity, since the former measures the effectiveness of the host response, which is determined both by the magnitude of the immune mechanism and the success of the escape mechanism. Thus the MC3 sarcoma induces cytotoxic cells⁹ and antibody to approximately the same extent as highly immunogenic tumours. The lack of immunogenicity of tumours such as MC3 has been ascribed to a high rate of shedding of tumour-specific antigen into the circulation¹⁰, which combines with and neutralises cytotoxic lymphocytes before they can reach the tumour. The initiation of an immune reaction by itself is, therefore, not sufficient to induce a macrophage infiltration, there must be an effective immune reaction at the tumour site for this to occur. Thus, as in a delayed hypersensitivity site, while the presence of macrophages is an essential component of such a reaction, these cells do not appear until an interaction of immune lymphoid cells with the eliciting antigen has occurred. We have previously shown¹¹ that tumour-bearing animals become progressively less responsive to DHS skin testing antigens and inflammatory stimuli, and it seems that this may be due to a competition of growing tumours for available monocytes, since the magnitude of the defect was directly related to the number of macrophages sequestered in the tumour of the rat being tested.

What then is the role of macrophages in tumours? Are they ineffectual bystanders brought in by lymphokines released in an immune process effected entirely by lymphoid cells interacting with the tumour? Though this remains a possibility, the clear demonstration of an immunologically specific cytotoxicity of macrophages to syngeneic sarcoma cells¹² makes this unlikely and the available data are more

consistent with the view that macrophages in the tumour play an active part in preventing metastatic spread. They may also contribute by phagocytosing tumour breakdown products, thereby reducing the amount of soluble antigen released into the circulation.

We thank Dr R Evans for advice, and the Medical Research Council and Cancer Research Campaign for support.

Antibody cell daughters can produce antibody of different specificities

ALTHOUGH it contradicts current dogma, there is considerable indirect evidence for the idea that most antibody diversity is generated only after B cells are stimulated to proliferate by antigens or mitogens¹⁻³. A prediction of this theory, confirmed here, is that there may be rapid production within single clones, of cells producing antibody of different specificities.

We characterised the specificity of antibody from single cells by its cross reactivity, using a modified version of the haemolytic plaque technique⁴. We tested antibody plaque-forming cells (PFC) not against a single type of red cell, but on a mixture of erythrocytes from two different individual sheep. Plaques were either clear (both red cells lysed), partial (only one lysed), or "sombrosos"⁵ with different degrees of lysis of both indicators (Fig. 1). The use of plaque morphology as a specificity marker has been fully justified elsewhere (A. J. C. and L. M. Pilarski, in preparation). It is not influenced by differences in amount of antibody since the morphology of a given plaque is faithfully maintained as it grows (A. J. C. and L. M. Pilarski, in preparation). Nor does it reflect changes in antibody class since, in our experiments, plaques were always direct, produced early in a primary response (1-3 d) and obtained from cultures stimulated with bacterial lipopolysaccharide⁶, all conditions which favour IgM.

Table 1 records that of 911 PFC cultured *in vitro* for 2 d, 93 gave rise to two or more plaque-forming progeny. Procedure B unequivocally established that all PFC came from the initial donor cell. With procedure A, controls showed that the probability of plaque formation by contaminating cells, or by irradiated cells, was very low.

In most cases, plaques produced by all progeny were strikingly homogeneous except for small variations in overall diameter. This seems to serve as a good control of the validity of the marker system. That is, different individual cells from the same clone usually made plaques which were morphologically identical. In 10 cases, however, there was obvious variation in the specificity of the antibody released by daughter cells. Seven of these microclones, (including the six where there were only

Fig. 1 Photographs (a-c), and diagrammatic representation (d-f), of clear (a, d), sombrero (b, e) and partial (c, f) plaques each produced by a single cell in a mixture of erythrocytes from sheep 1 and sheep 2. Illumination was dark field. In the diagrams, the circles and squares represent red cells of the two different types. A clear plaque is produced by antibody which is equally capable of binding to both indicator red cells. A partial plaque is produced by a different antibody specificity which binds to determinants accessible on one red cell type and not on the other. A sombrero is caused by antibody which binds to both kinds of erythrocyte, but to one better than the other. Mixtures of red cells from two different sheep have been used rather than from sheep and goat or cow as in earlier work^{12,13} so that clear and partial plaques would occur with about equal frequency, to allow the best chance of detecting a change from clear to partial or *vice versa*: the principle is the same whether red cells from two outbred individuals of the same or different species are used.

two plaques) showed two specificity types. Two of the clones contained what seemed to be plaques of three specificities (a clear plaque, a sombrero and partial). The most dramatic example of variation came from the culture of two large and tightly adherent cells (probably daughter cells) taken from the centre of a clear plaque in a microdrop, which on culture yielded a ball of 12 cells. Four of these gave similar plaques with a large clear centre, five produced sombreros with a tiny clear centre, one made a plaque which was possibly intermediate between these two types, one gave an entirely partial plaque, and one was undiagnosed since it was firmly stuck to one of the other cells (see below and Table 2). All of these plaques were similar in overall diameter, and all came from cells which looked macroscopically undamaged and were of similar size.

Sombrero plaques were a common result of these single-cell cultures. The ratio of overall (partial lysis) area to area of clear lysis can vary widely in such plaques, but in most single clones it was strikingly constant: if one plaque had a narrow 'brim' of partial lysis, then all showed exactly the same morphology.

Table 1 Numbers of PFC obtained from cultures of a single initial PFC*

		Yes			4										1‡

*Pooled results of all experiments.

†In all of these cases there were one or two large plaques and a large number (up to 60) tiny plaque-like areas with no central white cell, which were possibly caused by fragments of cytoplasm shed from antibody-containing cells.

‡This clone came from two tightly joined cells which were cultured together.

For procedure B, 10^7 spleen cells from one or more normal adult CBA mice were incubated in polyacrylamide rafts, as described by Marbrook and Haskill^{14,15}. Approximately 5×10^6 sterile sheep red cells were added, from any one of several commercial donor sheep. The medium was Eagles minimal essential, plus bicarbonate, with 10% added foetal calf serum. All cultures always contained *Escherichia coli* 0128:B12 lipopolysaccharide (Difco) at a final concentration of $7.5 \mu\text{g ml}^{-1}$. Rafts were incubated at 37°C in an atmosphere of 10% CO_2 and 83% N_2 , at pH 7.3. These cultures were collected at 24 h, when they had developed a total of 100–200 anti-sheep PFC. Cells from these 1 d mass cultures were dispersed under oil in microdrops containing a mixture of red cells from two standard sheep, (1 and 2) together with complement and medium¹⁶. The oil chambers were incubated horizontally for 15–30 min at 37°C , so that plaques could be seen around the rare antibody-forming cells. This period of incubation was kept as short as possible to prevent damage to the cells. For this reason the morphology of the plaque around the donor PFC was not always certain, although there was probably some selection for clear plaques which are easier to see than partials when small. The medium for these short-term incubations in an air atmosphere was 199 plus 10% foetal calf serum, buffered with 0.02 M HEPES. Individual PFC were now isolated from all other cells and micromanipulated out of the drops¹⁶. A single PFC was then transferred with a fine, hand-held micropipette to one of the microculture wells in a new polyacrylamide raft. These wells had each been pre-seeded with about 100 heavily irradiated (5,000 r.) normal CBA spleen cells and 1,000 sterile sheep red cells (again from any one of several commercial donor sheep), the medium being a mixture of equal parts of fresh Eagle's medium and filtered conditioned medium from the donor cultures. The individual PFC was observed at a magnification of $\times 40$ as it was pipetted on to the small pellet in the well. Rafts containing transferred PFC were then incubated for 42–48 h (in rare cases 18–24 h) at 37°C . After culturing, it was possible to identify those cells which had come from the original PFC by their large size, and because they were usually stuck firmly together in small clumps of up to 12 cells. They were sucked out of the well with a micropipette and separated by continuous sucking up and down, where necessary with the addition of trypsin at a final concentration of about $100 \mu\text{g ml}^{-1}$ to the drop for 1–20 min. Not infrequently, two or more cells could not be separated. The cells were then added to a mixture of fresh medium, complement, and red cells from the two standard merino sheep, 1 and 2. The mixture was pipetted into a slide chamber⁴, incubated for 1 h, and the resulting plaques characterised as having clear, partial or sombrero morphology. Procedure A was used for earlier experiments in which a larger number of feeder cells was used and 20–100 random normal cells were transferred and cultured together with the single PFC.

Contrasted with this were the instances of heterogeneous clones. Table 2 records the sizes and relative areas of clear and partial lysis in one representative homogeneous clone, and in two of the clones obtained by procedure B which were classified as showing variation.

The frequency of variation shown by cells in our cultures is obviously much higher than has been previously thought to occur. Assuming an average of two divisions per microclone we estimate about one variation event (mutation or gene switch) per 30 divisions. We have also obtained evidence for a similar rate of variation in limit dilution cultures of spleen cells both *in vitro* and *in vivo* (L. M. Pilarski and A.J.C., in preparation). There are a number of possible reasons why the method we have used has detected many more variants than other methods, the most important being its sensitivity. The plaque technique can pick up a single cell which is different from the rest of a clone. It is also extremely sensitive in that when two closely similar antigens (red cells from two sheep) are used, it seems reasonable that a small change in antibody structure may produce a slight increase or decrease in avidity for one antigen without affecting avidity for the other, resulting in a measurable change in plaque morphology, for example the plaque may change from clear to sombrero. Our conditions (IgM antibody, mitogen stimulation, early stages of clonal development), may also favour variation by comparison with most other clonal work, which has usually been done on protracted cultures of antibody-forming cells or myelomas, (for example refs 7,8). Frequently, the methods used to characterise such antibody as 'monoclonal' would not detect 5% of variants.

The only other attempt to detect clonal variation using the same marker as ours is the work of Nossal and Lewis¹³ who found no variants in the two daughter cells from each of 13 PFC, by testing plaques on a mixture of sheep and goat red cells. According to the rate of variation which we have observed this was too small a number of divisions for a variation event to be expected.

Other groups^{9,10} have recently looked for variation in cultured myeloma cells, using techniques which would probably

detect mainly large changes in Ig structure. Nevertheless, Bauml *et al.*⁹ demonstrated a fairly high rate of variation under some culture conditions, leaving open the possibility that small undetected changes in the V region may also have been common.

Our experiments support the idea that antibody diversity can be generated at a high rate after immunocompetent cells are stimulated to proliferate. The experiments describe antibody phenotype only, and do not elucidate the genetic basis for clonal variation. Baltimore¹¹ has recently described a possible mechanism of hypervariation. The small changes in specificity which we observe might well be due to point mutations in the V region (hypermutation), but we cannot entirely exclude rapid switching from one pre-existing gene to another.

We acknowledge discussions with Linda Pilarski and Kevin Lafferty. Ralph Westen took the photographs.

Spontaneous antilymphoma reaction of preleukaemic AKR mice is a non-T-cell killing

THE high incidence of spontaneous leukaemias in AKR mice may be explained by the early appearance and high level of replication of a type C virus. It is often suggested, however, that in addition, AKR mice could be tolerant to their leukaemias. This tolerance would enhance the *in vivo* growth of malignant cells. In fact, AKR mice are not completely devoid of antileukaemic immune response¹⁻³. It would be interesting, therefore, to determine if a quantitative or qualitative defect of one given type of antileukaemic response exists in AKR mice. Previous work has shown that an antibody response directed against the type C virus or against antigens of leukaemic cells can be demonstrated not only in hyperimmune¹ but also in normal AKR mice⁴.

A cell mediated reaction directed against G (Gross)⁵ leukaemia antigen-bearing cells was also detected *in vitro*^{5,7} but this cell-mediated reaction was characterised by inhibition of the growth of G+ cells in monolayers. It is now known, however, that this kind of inhibition can be due to non-T cells⁷⁻⁹ and could be antibody dependent¹⁰. A completely different cell-mediated antitumour reaction can be evidenced in the murine sarcoma virus (MSV) induced tumour system by the chromium release test (CRT) which detects a pure T-cell-mediated^{11,12} and antibody-independent¹³ cytotoxicity of tumour cells. Our work was performed to determine if AKR mice are capable of spontaneously developing such a kind of T-killer cell response.

AKR, C₃H/He, BALB/c and C57BL/6 mice were from our own colony. They have been tested at various ages from 2 weeks to 19 months without any preliminary treatment. Both males and females were used and tested individually. The CRT was done as previously described¹³. The effector cells were spleen cells, and the tumour target cells were lymphoma cells in suspension. A 100:1 effector:target cell ratio was used. The serologically defined tumour antigens and the origin of the target cells are given in Table 1. The specific chromium release was measured after 18 h incubation of target cells in the presence of effector cells. It was expressed as the excess of release when target cells were incubated with AKR spleen cells in place of C₃H/He, BALB/c or C57BL/6 control cells. No difference in the chromium release can be detected when non-AKR cells were used as effector, whatever the age of the donor mice. As previously discussed, an excess of 4% in the chromium release can be considered as significant¹³.

Results of experiments in which the effectors were whole spleen cells are given in Table 1. Individual AKR mice less than 3 months old were constantly negative. Positive CRT was found in 75% of 3-5-month-old AKR mice. The reaction was generally weak (specific release average = 12%), but could occasionally reach a high level (20-30%). Not only syngeneic or allogeneic G+FMRGi- lymphoma cells, but also G-FMRGi+ lymphoma cells could be lysed by the AKR spleen cells. Such a cross reaction was previously observed in MSV tumour system^{13,14}. ERLD lymphoma and P815 mastocytoma, which bear no serologically defined leukaemic antigen⁵, were never lysed by AKR spleen cells. Leukaemia of AKR mice began to appear after 5 months. Positive CRT reactions were observed in 41% of non-leukaemic animals older than 5 months. These results show that positive reactions are less frequent than in younger mice. In addition, positively-reacting animals were more frequent between 5 and 8 months (57%) than after 8 months (30%). CRT reactions were always negative in mice with overt leukaemia (enlargement of spleen, lymph nodes and thymus).

Table 2 Effect of anti- θ AKR serum and complement treatment on the activity of spontaneously cytotoxic AKR spleen cells for the GL 3 lymphoma of C57BL/6 mice

Spleen cells from AKR	Specific chromium release (%) in the presence of reactive spleen cells treated by:				
	Medium alone	C ₃ H normal serum with complement	C ₃ H normal serum without complement	C ₃ H anti- θ AKR serum with complement	C ₃ H anti- θ AKR serum without complement
4 months old	25	23	22	27	28
5 months old	19	17	20	22	21
6 months old	11	12	9	13	12
7 months old	8	7	8	10	7
8 months old	15	12	13	14	13

These results suggest that AKR mice can develop a spontaneous antileukaemic reaction which appears during the preleukaemic period and completely disappears with the progression of the disease. It was previously shown that the CRT allows the detection of a pure T-killer cell phenomenon in our MSV tumour system^{11,12} as well as during allograft rejection^{15,16}. Thus, we have attempted to discover whether T cells could be responsible for the spontaneous CRT reactions detected in AKR mice. The whole spleen cell suspensions of individual AKR mice were treated with C₃H/He anti- θ AKR serum diluted at 1:10 and rabbit complement, before they were used in the CRT. Anti- θ AKR serum was obtained by repeated inoculations of AKR thymocytes in C₃H/He mice, the serum was absorbed by C₃H/He thymocytes and tested for its specificity for various lymphoid organs of AKR mice. Controls included in each experiments were first, AKR spleen cells treated by normal C₃H/He serum and rabbit com-

plement. It can be concluded that the positive results obtained in the CRT with AKR spleen cells were due to non-T cells.

To study the nature of the effector cells, spleen cell suspensions from individual AKR mice were treated according to one of the following procedures (Table 4): first, incubation for 30 min at 37° C with carbonyl iron followed by six successive passages over a powerful magnet¹⁶. This procedure removes practically all the macrophages. Second, filtration through anti-immunoglobulin-coated glass bead columns according to the method of Wigzell *et al.*¹⁷. This method removes both the macrophages and the immunoglobulin-bearing lymphocytes, and the eluted suspensions contain about 90% T cells. Third, incubation for 20 min at 37° C with 0.25% trypsin. The reaction was stopped by the addition of five volumes medium containing 10% foetal calf serum. This method allows the eventual removal of antigen-antibody complexes attached to effector cells. The results (Table 4) show that column filtration

Table 3 Effect of anti- θ AKR serum and complement treatment on the activity of anti-C57BL/6 immune AKR spleen cells for the GL 3 lymphoma of C57BL/6 mice

Anti C57BL/6 immune spleen cells from AKR	Specific chromium release (%) in the presence of immune spleen cells treated by:				
	Medium alone	C ₃ H normal serum with complement	C ₃ H normal serum without complement	C ₃ H anti- θ AKR serum with complement	C ₃ H anti- θ AKR serum without complement
2 months old	31	38	35	0	33
5 months old	23	26	24	0	27
8 months old	36	37	34	0	38

plement and, second, AKR spleen cells treated by anti- θ AKR serum without complement.

The results of a typical experiment are summarised in Table 2. They show that the elimination of θ antigen-bearing cells does not decrease the antileukaemic response of AKR spleen cells. Twenty-three positive mice were individually studied giving identical results. It is unlikely that these results would be a consequence of a weak activity of the anti- θ AKR serum used, since this serum lyses all T-cells of AKR mice at dilutions up to 1:100 and because AKR receiving 4×10^7 C57BL/6 spleen cells intraperitoneally have cytotoxic lymphocytes in CRT for C57BL/6 target cells and pretreatment of these cytolytic cells with anti- θ AKR serum diluted at 1:10 and rabbit complement abolish their activity (Table 3). In addition, this last result demonstrates clearly that AKR mice are perfectly able to develop a T-killer cell response against an allogeneic

strongly decreases the CRT activity of spleen cells, and carbonyl iron treatment abolishes it completely. Identical results were obtained with the 18 reactive mice tested. It can be concluded that non-T cells, probably macrophages, are the main effector cells of the spontaneous CRT reactions of preleukaemic AKR mice. Treatment of spleen cells with trypsin suppress the CRT activity (Table 4), and this activity does not reappear even 24 h after trypsinisation. It is likely, therefore, that an antibody-dependent cell-mediated reaction is involved. We are studying the capacity of various AKR sera to block reactive cells and to 'arm' nonreactive cells in CRT.

Three points should be noted. First, an antileukaemic reaction can be detected by the CRT in preleukaemic AKR mice, but this reaction, probably antibody mediated, is unable to protect the mice since it was found in at least 75% of 3-5-month-old AKR mice, whereas the incidence

Table 4 Effect of various treatments on the cytotoxic activity of reactive AKR spleen cells

Spleen cells from AKR	Specific chromium release (%) in the presence of reactive spleen cells treated by:			
	Medium alone	Column filtration	Carbonyl iron and magnet	Trypsin
4 months old	11	0	0	0
4 months old	21	7	0	0
5 months old	16	4	0	ND
7 months old	12	0	0	0
7 months old	9	0	ND	0
8 months old	8	0	0	0

of leukaemia in AKR mice is about 80%.

Second, we have demonstrated^{11,12} in the MSV tumour system that the CRT allows the detection of pure T-cell killing of syngeneic tumour cells. Similar observations were done previously in allogeneic immunisation¹⁵⁻¹⁶. In the same experimental conditions, however, the AKR spontaneous reaction is caused by non-T cells. Immune cytolysis of P 815 tumour cells resulting from non-T cells have been also detected in old NZB mice¹⁸. Furthermore, it is known that in the microtoxity assay (MA) both T and non-T cells^{7,8} and even macrophages⁹ can be involved. It therefore seems necessary to determine precisely the nature of the effector cells for each tumour system, whatever the *in vitro* methods used to study the cell-mediated immunity.

Third, the absence of T-killing in the antileukaemic response in preleukaemic AKR mice must be emphasised since the same animals can respond normally to allogeneic grafts with a high level of specific T-killer cells. The existence of such a reaction not only in young AKR but also in 8-month-old mice is especially interesting and suggests that a decrease with aging in the immune competence of AKR is not involved. It is noteworthy that the same AKR mice which develop anti-allogeneic T-killer cells can have at the same time a non-T cell mediated reaction directed against syngeneic G+ lymphoma. The first reaction is abolished by anti- θ AKR whereas the second remains unchanged. Preliminary results indicate that the absence of T-killer response is not a general property of the leukaemia viruses since resistant mice such as C57BL/6 are able to develop a 'T' response after Friend or Moloney virus inoculation (unpublished data). Further experiments in the Gross system using both sensitive and resistant mice are now in progress to determine whether the absence of T-killer cell response is a property of AKR mice or not. A hypothesis would be that the *Rgv-1* gene¹⁹ which conditions the sensibility to Gross virus induced leukaemias could be responsible for the AKR inability to develop an antileukaemic T-killer cell response. This hypothesis could be reinforced by the fact that an H-2-linked gene, possibly identical to *Rgv-1* mapped in the H-2 complex near the 'Ir region'²⁰ has been recently shown to act like an immune response control gene²¹.

Observations on the mechanism by which T-lymphocytes exert cytotoxic effects

The mechanism by which T lymphocytes kill tumour cells is unknown¹. The killing is more rapid than reported for lymphotoxin². Among possible mechanisms are the involvement of complement components³ or phospholipase A, which could generate lysolecithin in the target cell membrane. To test these possibilities we have examined the rates of release from tumour cells of markers of high and low molecular weight and the effects of nonpenetrating solutes. If killing involves disruption of the structure of the cell membrane, for example by lysolecithin, simultaneous release of markers and no protection by macromolecular solutes would be expected. If lysis is osmotic, markers of low molecular weight should be released before those of high molecular weight and nonpenetrating solutes should protect against the lysis by counterbalancing the intracellular osmotic pressure. In the case of complement lysis, small macromolecules of molecular weight less than 40,000, which

Fig. 1 Time course of the specific release of ⁸⁶Rb (O-O) and ⁵¹Cr (●-●) from mastocytoma cells by sensitised spleen cells. P-815-X2 mastocytoma cells were double labelled: 5×10^6 cells were incubated for 1 h at 37° C with 100 μ Ci of $\text{Na}_2^{51}\text{CrO}_4$ and 1000 μ Ci of ⁸⁶RbCl in 1 ml Eagle's minimal essential medium containing 10% foetal bovine serum. Sensitised spleen cells were obtained from C57BL/6 mice injected intraperitoneally 11 d earlier with 3×10^7 live mastocytoma cells. Mixtures containing 10^7 normal or sensitised spleen cells and 1.5×10^5 labelled mastocytoma cells in 1 ml of the above medium were centrifuged in flat bottomed plastic tubes of 1.25 cm diameter and incubated at 37° C for the indicated lengths of time. Then they were mixed, briefly centrifuged and aliquots of supernatants taken for counting the released labels. Percentage specific release of the two labels was obtained by subtracting the release in the presence of normal spleen cells from the release in the presence of sensitised cells and is expressed as a fraction of the total labels released by freezing and thawing the cells. The values are means of duplicates and the range of variation is indicated.

penetrate through complement lesions, do not inhibit lysis, whereas those of molecular weight above 40,000 protect⁴.

Our experiments have been performed with a widely studied cytotoxicity model, mastocytoma cells from DBA/2 mice and sensitised lymphocytes from C57BL/6 mice¹. As a convenient small marker we have used ⁸⁶Rb⁺, which is not bound in the cytoplasm and behaves in a manner analogous to K⁺, and as a large marker ⁵¹Cr which is bound to cytoplasmic protein. The time course of release of the two markers is shown in Fig. 1. It is clear that the specific release of ⁸⁶Rb⁺ occurs much more rapidly than that of ⁵¹Cr, as previously reported by Henney⁵. In contrast to Henney⁵, but like C. J. Sanderson and G. A. Taylor (unpublished), we find linear release of ⁵¹Cr from the time of contact of effector lymphocytes and target cells. The slope of the curve

Table 1 Effect of dextran on release of ⁵¹Cr and ⁸⁶Rb from mastocytoma cells by sensitised lymphoid cells

Experiment No.	Time (min) when dextran added	Isotope released	% inhibition of specific release	
			15–20 min*	40–45 min
1	5	⁵¹ Cr	70 ± 1.7	44 ± 1.1
1	5	⁸⁶ Rb	14 ± 1.8	0 ± 1.4
2	15	⁵¹ Cr	53 ± 1.9	51 ± 1.6
2	15	⁸⁶ Rb	0 ± 2.1	0 ± 2.0
3	20	⁵¹ Cr	37 ± 0.7	30 ± 0.6
3	20	⁸⁶ Rb	0 ± 0.9	0 ± 1.1

*Time after dextran addition.

The cytotoxicity assays were carried out as in Fig. 2, but with varying time intervals before and after the addition of dextran solution to the cell mixtures

Fig. 2 Effect of dextran on the specific release of *a*, ⁸⁶Rb and *b*, ⁵¹Cr from mastocytoma cells by sensitised lymphoid cells. Spleen cell–target cell mixtures ($10^7 : 1.5 \times 10^5$ in 0.5 ml) were centrifuged and incubated at 37° C for 20 min. At that point (shown by arrow) 0.5 ml of a solution of 24% dextran molecular weight 10,000 daltons was added to some 0.5 ml cell suspensions and all samples were incubated for a further 20 min before the release of the two labels was assessed in the presence (O) or absence (●) of dextran.

of ⁵¹Cr release is related in a linear fashion to the concentration of the effector cells. These observations allow three conclusions. First, the cytotoxic mechanism depends on contact of one effector cell with a target cell. Second, within minutes of the establishment of such a contact the plasma membranes of the target cells show increased permeability to ions but not proteins. Third, loss of cytoplasmic proteins follows a slower, linear time course beginning in some cells within a few minutes of contact and occurring in other cells only after a delay of an hour or more.

Although several nonpenetrating solutes were found to inhibit the lysis of target cells, most experiments were performed with dextran of molecular weight 10,000 (T 10). Representative experiments with dextran T 10 in the extracellular medium are shown in Table 1 and Fig. 2. When the dextran was added at the beginning of the experiment, inhibition of the release of ⁸⁶Rb as well as of ⁵¹Cr was found, presumably because effective contact of the lymphocytes and target cells was prevented. When dextran was added after 5 min there was only slight inhibition of ⁸⁶Rb release (possibly because effective contacts between lymphocytes and all target cells had not yet been established) but there was much greater (70%) inhibition of ⁵¹Cr release. Addition of dextran as late as 20 min still produced highly significant inhibition of ⁵¹Cr release but none of ⁸⁶Rb release. This effect was fully reversible: when medium containing dextran was replaced with medium lacking dextran, the release of ⁵¹Cr proceeded rapidly to completion. Hence the presence of dextran does not affect the increased permeability of target cell membranes to ions but produces a marked and reversible inhibition of the release of cytoplasmic proteins.

The kinetics of release of large and small markers and the protection against loss of large markers by low molecular weight dextran provide strong evidence that the lysis of tumour cells by sensitised T lymphocytes occurs through osmotic effects and that the ion-conducting channels formed in the plasma membrane of the target cells are smaller than those produced by complement. As shown in Table 2, neither the osmotic lysis produced in the same target cells by antibody and complement nor that produced by lysolecithin is appreciably affected by dextran of molecular weight 10,000.

It has been reported that cooling the injured target cells to 0° C in the effector cell independent phase of the reaction prevents ⁵¹Cr release⁶. This observation was interpreted as evidence in support of an enzymic reaction. An alternative explanation is that because of loss of fluidity in the target cell membrane the ion-conducting channels generated following contact with effector lymphocytes are sealed at low temperatures. As shown in Fig. 3, cooling to 10° C inhibits almost completely leakage of ⁸⁶Rb as well as ⁵¹Cr from the target cells. In other experiments ⁸⁶Rb and ⁵¹Cr release were markedly depressed even at 15° C, and returned to control levels when the cells were placed again at 37° C. These observations support the view that membrane fluidity is

Fig. 3 Effect of lowering temperature on *a*, ⁸⁶Rb and *b*, ⁵¹Cr release from the mastocytoma cells. Spleen cell–target cell mixtures were prepared as in Fig. 1 and incubated at 37° C for 15 min. Then some cell samples were cooled to 10° C and all cell samples were incubated at the appropriate temperatures for up to 60 min. The labels released from the target cells in presence of sensitised (●) or normal (O) spleen cells at 37° C (—) or at 10° C (---).

involved. Even the basal release of ^{86}Rb in the absence of specific effector cells is markedly reduced at $10^\circ\text{--}15^\circ\text{C}$, which is again consistent with a requirement for membrane fluidity.

These observations help to clarify the mechanism by which sensitised T lymphocytes lyse target cells. The first stage is the establishment of effective contact between effector cells and target cells. This requires effector cells which are living and moving: inhibition of motility of the cells by cytochalasin^{7,8} blocks the early but not the later stages of the reaction. The inhibition of target cell lysis by agents generating cyclic AMP⁹⁻¹¹ may exert their effects by depressing movements of effector cells. Movement is required for three reasons: bringing effector cells and target cells together, moving apposed membranes to establish intimate contact of appropriate type, and subsequent movement of the cells apart. Once effective contact of lymphocytes and target cells is established (which begins within a few minutes of their coming together) killing the lymphocytes by specific antibody and complement does not prevent continued lysis of target cells: intact effector cells are not required for the final lytic process¹². In fact, the films of Ginsburg and Ax¹³ show that lysis does not take place while the effector cell and target cell are in contact but occurs only after the effector cell has disengaged itself and moved on. The films also show that the diameter of mastocytoma cells is increased before lysis, which is consistent with the interpretation that osmotic swelling is taking place.

Table 2 Effect of dextran on the lysis of tumour cells by antibody and complement and by lysolecithin

Lytic agent	Dextran	% Specific ^{51}Cr release	% Inhibition by dextran
Antibody	—	91 \pm 0.9	—
Antibody	T 10	86 \pm 0.2	6
Antibody	T 40	46 \pm 2.3	50
Lysolecithin	—	100 \pm 0.2	—
Lysolecithin	T 10	100 \pm 0.1	0

Tumour cells were incubated with a minimum lytic concentration of rabbit antiserum against mastocytoma cells and guinea pig complement (4 haemolytic units) or with lysolecithin ($20\text{ }\mu\text{g ml}^{-1}$) for 1 h at 37°C . Lysis in the presence and absence of dextran (12%) was compared. The ^{51}Cr release by antibody was compared with that produced by freezing and thawing cells, and that by lysolecithin, which was higher, compared in the presence and absence of dextran.

During the second phase of the reaction the plasma membrane of the target cell becomes leaky to ions. The underlying mechanism is not yet certain. An appealing hypothesis is that a gap junction is established between the effector and target cell. The report of Sellin and his colleagues¹⁴ that fluorescein passes from target cells to sensitised lymphocytes supports this interpretation. The electrotonic coupling, involving free passage of ions, of lymphocytes treated with phytohaemagglutinin¹⁵ is also relevant since this lectin can promote lysis following contact between effector cells and target cells¹⁶. Gap junctions are characterised by clusters of particles in apposed membranes demonstrable by freeze-fracturing electron microscopy¹⁷, and it is conceivable that crosslinking of proteins in the membrane of the target cell by specific receptor molecules on the surface of the lymphocyte (by a process analogous to patching¹⁸) may be involved in the generation of gap junctions, and also in the persistence of such leaky complexes, allowing increased passive ion flux in the membrane of the target cell once the lymphocyte has moved away.

The experiments reported in this paper seem to exclude a role of lysolecithin generation or of typical complement-induced membrane lesions in the lysis of tumour cells by sensitised T lymphocytes. A second phase of lysis, which does not require the presence of intact effector cells, is characterised by increased permeability of the target cell

membrane to ions but not to cytoplasmic proteins, and the final lytic event is due to osmotic effects. The nature of the lesion in the target cell membrane is not yet certain, but it may be due to the formation and persistence of a gap junctional complex.

Rapid mixed lymphocyte culture test based on relative increase in protein synthesis

WE have developed a mixed lymphocyte culture assay for matching prospective recipients of organ transplants to donor cadavers. Its rapidity, combined with the use of frozen cells from a recipient panel, could facilitate the sharing of cadaveric organs among transplantation centres.

Allogeneic lymphocytes mixed in culture stimulate each other and undergo blastogenesis to a degree proportional to the degree of antigenetic disparity between the cells. This mixed lymphocyte reaction (MLR) is a precise means by which the graft *versus* host response can be estimated *in vitro*. MLR is usually evaluated by the measurement of DNA synthesis in 5-8-d-old mixed lymphocyte cultures (MLC). Although the MLC test has been used for the study of some aspects of histocompatibility in man, its use for matching donors to recipients for cadaveric organ transplantation has been limited by the length of the test. A more rapid test (72 h) measuring stimulation of DNA synthesis in MLC has been reported¹, and a method for early evaluation (11-24 h) of mixed leukocyte interaction in mice and

Table 1 MLR after inhibition of protein synthesis in stimulating lymphocytes

Lymphocytes	c.p.m. ^3H -leucine 1 h pulse	c.p.m. ^3H -thymidine 8 h pulse (5 d culture)
C	1220	307
D	1170	342
D _m	1008	96
D _e	112	42
D × D _e	1216	324
C × D	6978	2176
C × D _e	1357	298
C × D _m	5109	1585

The effects of emetine on stimulation of DNA and protein synthesis in MLR. Suspensions of lymphocytes (C) and (D) were prepared as described in the text (2×10^6 cells ml^{-1}). Lymphocytes D were arbitrarily selected as stimulating cells and were treated with $25 \mu\text{g ml}^{-1}$ mitomycin C for 30 min at 37°C and used in MLC after excess mitomycin was removed by three washes with medium. Similarly, lymphocytes D were treated with 1 mg ml^{-1} emetine for 30 min and used as D_e after three washes. Both mitomycin-treated (D_m) and emetine treated (D_e) cells remained viable (97%) as tested by trypan blue exclusion. Lymphocytes C and D (D_e and D_m) were incubated alone or mixed together and incubated in leucine-deficient medium in the presence of ^3H -leucine $0.001 \mu\text{mol ml}^{-1}$ for 1 h, collected and counted for ^3H incorporation. They were also cultured alone or mixed together and cultured for 5 d in chemically defined medium³ containing 5% calf serum. On the fifth day cells were collected 8 h after the addition of $10 \mu\text{Ci ml}^{-1}$ of ^3H -thymidine. Incorporation of ^3H -thymidine was measured by scintillation counting. A mixture of DD_e was used to rule out possible carry-over of excess emetine by D_e.

guinea pigs based on the measurement of protein synthesis has been described²⁻⁴. We now report a rapid MLC assay (1 h) to discriminate between isogeneic and allogeneic human lymphocytes by measuring the relative increase in the rate of protein synthesis in MLR. The assay allows the use of frozen lymphocytes from a panel of prospective recipients.

Using a synthetic medium⁵ free of leucine, we compared the changes in the rate of ^3H -leucine incorporation into proteins of allogeneic lymphocytes. Leukocyte-rich plasma was obtained from heparinised blood after red blood cell sedimentation, and the leukocytes were isolated by centrifugation (10 min at 150g). Lymphocytes were separated from granulocytes and red blood cell contaminants by discontinuous density gradient centrifugation⁶.

Protein synthesis was measured as described in the legend to Fig. 1. The first increase in protein synthesis of MLR appeared as a distinct increase in the rate of ^3H -leucine incorporation beginning as early as 15 min after lymphocytes were mixed in culture. This increase lasted for about 4 h and then declined to a rate more characteristic of unstimulated lymphocytes. The second phase, probably more intimately related to DNA synthesis, appeared about 12 h after the initial contact of allogeneic lymphocytes in culture. This phase seems to correspond to the stimulation of protein synthesis reported in MLR of guinea pigs and mice²⁻⁴.

The first phase of stimulation constituted the basis for the test. Lymphocytes were separated from their medium by filtration and cellular proteins and the proteins released

Table 2 Correlation of stimulation ratio in rapid and standard MLC

Lymphocytes in MLC	Stimulation ratio	
	DNA synthesis	Protein synthesis
A × Z	3.7	2.7
B × Z	4.0	3.2
C × Z	6.2	4.8
D × Z	9.6	10.0
E × Z	18.5	15.6

Correlation of protein synthesis in rapid MLC with DNA synthesis in 5 d MLC. Triplicate cultures were prepared described in Table 1, and stimulation ratios were calculated as follows c.p.m. of A × Z/1/2 c.p.m. of A + 1/2 c.p.m. of Z and so on. Lymphocytes A, B, C, D and E showed similar degrees of stimulation of DNA and protein synthesis by cell Z in two-way reactions.

into the medium by the lymphocytes were isolated. The patterns of leucine incorporation into these proteins after electrophoresis on polyacrylamide gel⁷⁻⁹ were compared with those of isogeneic lymphocytes in culture (Fig. 2). The results indicate that a major portion of the increase of radioactivity in MLC is associated with the proteins excreted into the medium. The pattern of ^3H -leucine incorporation into proteins of allogeneic lymphocytes changes within 1 h of initial contact between these cells. The appearance of new and high peaks of leucine uptake suggests the synthesis of new proteins in stimulated cells.

To confirm the participation of both cell types in the

Fig. 1 Biphasic protein synthesis in MLR: protein synthesis was measured by uptake of ^3H -leucine into acid-precipitable proteins. Allogeneic lymphocytes A and B (2×10^6 cells per ml) were incubated in a medium with low concentrations of leucine ($1 \mu\text{mol l}^{-1}$) by themselves or mixed (A:B=1) at 37°C for up to 24 h. Ten cultures of each type (A, B and A × B) were collected at each time point. For the first three time points (15, 30 and 60 min), $0.001 \mu\text{mol ml}^{-1}$ of ^3H -leucine was added to each culture at the plating time and cultures were collected after 15, 30 and 60 min of incubation. Other cultures were collected at 2-4 h intervals 1 h after the addition of $0.001 \mu\text{mol ml}^{-1}$ of ^3H -leucine. The total acid-precipitable protein of the medium and cells of each culture was collected on Millipore filters ($0.2 \mu\text{m}$ pore size), dried and counted in a scintillation counter. ○, Mean c.p.m. of allogeneic MLC (A × B); ●, 1/2 mean c.p.m. of lymphocyte A + 1/2 mean c.p.m. of lymphocyte B (A + B). The bars indicate ± 1 s.d.

first phase of protein synthesis, one cell type was pretreated with emetine¹⁰⁻¹², which irreversibly inhibits cell protein synthesis without affecting viability. This prevented stimulation of protein and DNA synthesis in allogeneic lymphocytes in MLC (Table 1), strongly suggesting that active protein synthesis in both the stimulating and responding cells is necessary for MLR. This reaction, at least in the early phase of MLC, is a two way response.

In our leucine-free medium, the addition of a minimum of $0.001 \mu\text{mol ml}^{-1}$ of labelled leucine was required for an adequate response (Fig. 3). Different degrees of uptake of ^3H -leucine occurred when the leucine concentration was varied. Detection of stimulation of protein synthesis in a given pair of lymphocytes was optimal with $0.001 \mu\text{mol l}^{-1}$ of leucine (Fig. 3).

We have compared the stimulation ratio (c.p.m. of MLC per c.p.m. of individual allogeneic lymphocytes in culture)

Fig. 2 Electrophoretic patterns of ^3H -leucine-labelled proteins of stimulated (●) and unstimulated (○) lymphocytes. Lymphocyte cultures were prepared as described in Fig. 1: $0.001 \mu\text{mol ml}^{-1}$ of ^3H -leucine was added to each culture at the time of plating and incubated for 1 h. Lymphocytes were separated from their culture medium by filtration through a Millipore filter ($0.45 \mu\text{m}$ pore size). Cells were suspended in 0.4 ml of 0.05 M Tris-HCl, $\text{pH } 7.4$, and mixed with 0.8 ml of 2% sodium dodecyl sulphate (SDS) solution containing 6 M urea and 25% mercaptoethanol and dissociated by heating at 100°C . Similarly, 0.4 ml of medium was mixed with 0.8 ml of 2% SDS containing 6 M urea and 25% mercaptoethanol and dissociated by heating at 100°C . Aliquots (0.1 ml) of each denatured solution were applied to 7.5% acrylamide gel columns prepared according to Russell and Skehel⁷⁻⁹ and electrophoresed for 8 h at 3 mA per gel. Gels were washed in 7% acetic acid and sliced 1 mm thick, each slice was solubilised in 0.1 ml of NCS (Nuclear Chicago) and counted in a scintillation counter after addition of counting fluid. *a*, Electrophoresis of proteins released into medium: ●, c.p.m. of stimulated lymphocytes ($A \times B$); ○, c.p.m. of unstimulated lymphocytes ($A + B$); *b*, electrophoresis of cellular proteins: ●, c.p.m. of stimulated lymphocytes ($A \times B$); ○, c.p.m. of unstimulated lymphocytes ($A + B$).

Table 3 Correlation of Rapid MLC with graft rejection

Number of cases	Rejection	Stimulation ratio	
		Range	Mean
4	0	1.2–1.8	1.65
8	1+	2.1–3.8	2.60
6	2+	3.4–4.8	4.05
3	3+	6.7–10.4	8.10
17	4+	3.8–24.8	11.60

Correlation of stimulation ratio in rapid MLC with graft rejection. Thirty-eight recipients of cadaveric kidneys were selected and transplanted on the basis of negative cross match. The stimulation ratios in rapid MLC were measured as described. Rejection was classified as follows: 0, no rejection—normal function (serum creatinin less than $1.5 \text{ mg}\%$); 1+, one rejection crisis, reversed—normal function; 2+, two rejection crises, reversed—less than normal function (serum creatinin more than $1.5 \text{ mg}\%$); 3+, two or more rejection crises, but kidney lost after 3 months; 4+, uncontrollable rejection requiring graft nephrectomy.

(A, B, AB or O) were mixed with lymphocytes of each recipient in the corresponding panel for the rapid MLC test. Thus a gradient of stimulation ratios was obtained, and the donor-recipient pair with the lowest stimulation ratios was selected. Stimulation ratios among a panel of recipients tested against lymphocytes of a cadaveric donor ranged between 2 and 30.

The rapid MLC test allows rapid selection of a suitable donor-recipient pair from a recipient panel based on the MLR. For the selection of donor-recipient pairs on this basis, however, the panel would have to contain a large pool of recipients to allow for the exclusion of those donor-recipient pairs that have a low stimulation ratio of protein synthesis but a positive cross-match. Our preliminary study

Fig. 3 The effects of variation of leucine concentration on detection of MLR. Allogeneic lymphocytes C, D, E and F were prepared as described in the text and suspended in leucine-free medium (2×10^6 cells per ml) in triplicate. They were incubated by themselves or mixed with lymphocytes A (2×10^6 cells per ml) for 1 h in the presence of variable amounts of ^3H -leucine. Radioactivity of incorporated leucine was measured as described for Fig. 1. Mean c.p.m. of stimulated lymphocytes are shown as $A \times C$, $A \times D$ and so on. The lower curves represent $1/2$ (mean c.p.m. A + mean c.p.m. B) and so on.

of protein synthesis in rapid MLC with the stimulation ratio of DNA synthesis in 5-d MLC of 500 related and 100 unrelated donor-recipient pairs. The stimulation of DNA synthesis in all cases correlated well with the increase in the rate of protein synthesis in rapid MLC (Table 2).

This method was used to pair prospective kidney transplant recipients and cadaveric donors. Frozen cells* from recipients were prepared and stored at -80°C in four panels according to their blood types (A, B, AB or O). Lymphocytes from cadaveric donors of a given blood type

in 10 cadaveric transplants suggested that the degree of survival of the renal transplant is inversely related to the magnitude of the stimulation ratio in rapid MLC¹³. Present data (Table 3) confirms our previous findings.

Use of immune lymphocytes to detect expression of herpetic genome

HERPES simplex virus DNA and RNA have been demonstrated in one specimen of cervical carcinoma¹ but these experiments are very difficult to reproduce, possibly because sophisticated hybridisation techniques must be applied to large amounts of tumour cells. In hamster fibroblasts transformed² by herpes simplex virus 2 (HSV-2), viral RNA sequences have been detected³, but not viral DNA; 60% of these transformed cells reacted with a herpesvirus antiserum, using immunofluorescence techniques applied to unfixed cells⁴, but the background of positive cells was 10%, in control cells not treated with HSV-2. To confirm or complement hybridisation and immunofluorescence techniques, alternative methods may be useful.

We have tried to transfer the nucleic acids of a transformed cell line to normal cells, and to check whether functional viral nucleic acid had been transferred, by assaying the recipient cells for herpetic antigen. For the assay, we used immune lymphocytes since we found that the donor transformed cells were susceptible to specific toxic action of lymphocytes from appropriately immunised animals (lymphocytotoxicity test); in addition, killed transformed cells could be used as antigens to stimulate lymphocytes from immune animals (one way mixed cultures). We shall first describe the antigenic characteristics of the transformed cells before reporting the attempts to transfer these properties to normal cells, by means of nucleic acid transfer.

To provide immune lymphocytes for the cytotoxicity test, 4 to 6-week-old hamsters were inoculated subcutaneously with 2×10^6 cells of the 333 line transformed by HSV-2. Tumours appeared 1-2 week later, in 80-100% of the inoculated animals. Four weeks after inoculation, hamsters were killed and a lymphocyte suspension was prepared from the spleen. Toxicity of these lymphocytes was tested⁵ on cells prelabelled with ⁵¹Cr; Table 1 shows that lymphocytes from tumour-bearing animals were the most toxic for the homologous HSV-2 oncogenic cell line but were also active on HSV-2 infected

cells. The effect was low or absent on a normal hamster cell line, as well as on an adenovirus type 12 oncogenic cell line (NilTr.). Conversely, hamsters inoculated intraperitoneally with ultraviolet-irradiated purified HSV-2 virions possessed lymphocytes which were the most toxic for HSV-2 infected cells, but also released ⁵¹Cr from HSV-2 transformed cells and from HSV-1 infected cells, and had no effect on normal hamster cells.

These experiments showed that 333 transformed cells can be used as herpetic antigen targets; to investigate whether they could be used as an antigenic stimulus, we combined two published methods: one showed that mixed lymphocyte cultures can be miniaturised and performed with whole heparinised blood, without purification of the lymphocytes⁶, and the other applied the mixed lymphocyte reaction to the detection of tumour antigens⁷. We inoculated hamsters subcutaneously with 2×10^6 cells from the 333 line and killed some of them at various times after inoculation; their heparinised blood was cultivated for 5 d in the presence of mitomycin C-treated 333 cells. Tritiated thymidine was added on the fourth day, and its incorporation counted on the next day. The index of stimulation was considered positive when lymphocytes incorporated at least three times more thymidine after cultivation in the presence of the antigen than after culture in nutrient medium alone. Immune lymphocytes

Table 1 Toxicity of immune lymphocytes for various target cells

Lymphocytes from hamsters inoculated with	⁵¹ Cr release after action on cells Transformed with HSV-2	Adeno-virus 12	Infected with HSV-2	HSV-1	Normal (C13)

Irradiated HSV-2 virions	25	0	3		
	35		51	23	0

* Specific ⁵¹Cr release (%).

Lymphocyte suspensions were prepared from spleens of hamsters which either bore a subcutaneous tumour resulting from inoculation of 333 cells 4 weeks previously or had been immunised by two intraperitoneal injections of 5×10^6 ultraviolet irradiated HSV-2 plaque-forming units. 10^6 lymphocytes were added to cups containing monolayers of 10^4 target cells, grown for 20 h after labelling with ⁵¹Cr; 18 h after lymphocyte addition, radioactivity released into 100 μ l of the supernatant was counted.

showed the highest index of stimulation when collected 1 week after inoculation of the antigen; the index decreased below significant values when the tumour appeared, a confirmation of other observations⁷. Table 2 shows the results obtained with lymphocytes collected one week after inoculation of the antigens. Lymphocytes from hamsters immunised with 2×10^6 HSV-2 transformed cells, or with ultraviolet-irradiated HSV-2 virions, were stimulated specifically by the transformed cells. Hamsters inoculated with 2×10^6 HeLa cells, or with 10^6 - 10^8 normal cells aspirated from the cervix of healthy women, did not react; however, one hamster showed a weak but significant reaction with the 333 cells after inoculation with about 10^4 cells from a secondary culture of a biopsy of human carcinoma of the cervix. The specificity and reproducibility of the latter result must be confirmed. It has been shown recently⁸ that lymphocytes from women with cervical cancer were cytotoxic to HeLa cells, indicating the existence of an antigen common to these two types of cells; our results do not favour the hypothesis that this antigen is herpetic.

Having demonstrated that immune lymphocytes can detect herpes antigens in cells, we then tried to transfer the expression of these antigens to other cells by means of a nucleic acid transfer method used to rescue the SV 40 genome from transformed cells⁹; we chose this method because it was shown to be more efficient than cell fusion¹⁰. Hep-2 cultures were grown

Table 2 Mixed culture of immune lymphocytes with various mitomycin C-treated cells

Blood from hamsters inoculated with	³ H-Thymidine incorporation in the presence of cells	Transformed with HSV-2 (333)	Infected with HSV-2	Normal (C 13)
333 cells	36*			8
Irradiated HSV-2 virions	25		54	0
Human cervical carcinoma culture	4.3			1
Normal cervical cells	0.88 ± 0.48†		1.1	
HeLa cells	2.6		2.7	0.5

* Index of stimulation: amount of ³H-thymidine incorporated in the presence of stimulating cells divided by the amount incorporated after culture in nutrient medium alone.

† Mean ± s.e. of six tests performed after inoculation with 10⁵–10⁶ cervical cells from six women.

One week after a single injection of the antigens, hamster blood was collected with 10 U ml⁻¹ of heparin without preservative; aliquots of 0.1 ml of blood were added to 2 ml nutrient medium with 5% inactivated foetal calf serum, containing 4 × 10³ stimulating cells pre-treated for 30 min at 37° C with 60 µg ml⁻¹ of mitomycin C. After 4 d culture, 1 µCi ³H-thymidine ml⁻¹ was added and 24 h later the amount of label incorporated into acid-insoluble material was counted.

for 24 h after treatment with nucleic acids from 333 or Hep-2 cells, or from HSV-2 virions; they were then either labelled with ⁵¹Cr and used as targets for spleen lymphocytes from hamsters immunised with HSV-2 grown in Hep-2 cells; or they were treated with mitomycin C and used as stimulating antigens in mixed cultures with heparinised blood from the same immunised hamsters. In both tests, lymphocytes immune to HSV-2 reacted with Hep-2 cells treated with nucleic acids from the transformed cells, but not with untreated Hep-2 cells (Table 3). The immune lymphocytes also reacted with Hep-2 cells infected with either HSV-2 virions or HSV-2 DNA; the latter result is not unexpected since the experiment was done under the conditions used to demonstrate that HSV DNA is infectious^{12–14}. After treatment with nucleic acids from the transformed 333 cells, there was a zone phenomenon, since Hep-2 cells treated with 0.1 µg nucleic acids were more responsive than those treated with 5 µg. A nucleic acid transfer experiment was then repeated, using hamster C 13 cells as recipients; the appearance of herpetic antigens in these cells

Athymic (nude) mice express gene for myxovirus resistance

DISAPPOINTINGLY little is known about the mechanisms of natural, genetically determined resistance to infectious agents¹. Even in the simplest situation, where a single, dominant gene is responsible for resistance to a group of closely related viruses, no satisfactory explanation of the phenomenon has been offered. A case in point is the resistance towards the lethal action of a number of myxoviruses, mainly influenza A, exhibited by the inbred mouse strain A2G and attributed to the presence of the dominant gene *Mx* (refs 2–5). Serial virus titrations in A2G and comparable susceptible mice showed that resistance must depend on an event occurring early in the infectious process, since by day 2 after challenge virus titres were significantly lower in resistant animals². It was conceivable that an early triggering of the immune system might exert such an effect. If this were the case, one would expect the expression of the resistance gene to be impaired in mice showing profound disturbances of their immunological apparatus. Nude mice homozygous for the gene *nu* (refs 6–9) show such a disturbance, mainly of the T cell system. We have therefore introduced the gene *Mx* into *nu/nu* mice, and we have investigated the progeny from appropriate crosses for the phenotypic expression of resistance to neurotropic influenza virus.

Nude males (genotype *nu/nu* on a predominantly BALB/c genetic background, from G.L. Bomholtgard, Ry, Denmark) were mated with A2G females (*Mx/Mx*, bred locally). The F₁ generation was normal with respect to coat and thymus development, and was resistant to intracerebral challenge with 100 LD₅₀ (as estimated in susceptible mice) of neurotropic influenza A_v virus, strain NWS (ref. 3). Brother-sister matings

Table 1 Resistance of nude F_2 mice* to neurotropic influenza A virus

Experiment No.	No. challenged	Resistant†	Susceptible‡
1	9	8	1
2	11	8	3
3	11	8	3
Total	31	24	7

* 75% expected to be *Mx* carriers.† Survived intracerebral challenge with 100 LD₅₀ of stock NWS virus for 14 d or longer.

‡ Died of viral infection within 5–7 d.

among F_1 mice yielded an F_2 generation, of which approximately 25% were phenotypically nude. Assuming independent segregation of the genes *nu* and *Mx*, 75% of these nude F_2 should carry the gene *Mx* either in homozygous or heterozygous form. At the age of 3 weeks, nude F_2 together with comparable numbers of non-nude littermates, and with control resistant (*Mx*+) and control susceptible mice for monitoring the challenge virus, were inoculated intracerebrally with 100 LD₅₀ of NWS. All susceptible control animals succumbed to viral infection, whereas all control resistant *Mx*+/+ mice survived. Of both nude and non-nude F_2 mice approximately 75% survived. The results of the nude group are shown in Table 1; the observed seven deaths among 31 challenged mice are close to the expected 25%.

It is thus apparent that the nude phenotype did not preclude expression of virus resistance. The numbers observed also

antigen of influenza A virus. Tests on delayed hypersensitivity were not performed.

Expression of resistance in *Mx*-bearing mice seems therefore independent not only of a functional T-cell system, but also of the orderly development of HAI antibodies, usually regarded as the protective antibody in influenza virus infection. These findings agree with the observations that resistance of A2G mice could not be broken by various immunosuppressive regimens, including whole body X irradiation and neonatal thymectomy (P. A. Klein, personal communication, and unpublished work).

We conclude that the inborn resistance of mice carrying the dominant gene *Mx* does not require an intact immunological machinery for its expression. Both cellular and humoral immunity may be less important in recovery from influenza virus infection than hitherto suspected.

We thank Dr E. Müller for histological examinations, and Mrs M. Acklin and Miss R. Leemann for help.

Fig. 1 Serum antibody titres in myxovirus-resistant athymic and control mice surviving 100 LD₅₀ of influenza A NWS. ●, Congenitally athymic (nude) mice; ▲, non-nude littermates. a, Serum taken on day 14; b, serum taken on day 21.

suggest that the genes *Mx* and *nu* are not closely linked. To make sure that those mice which were assumed to be nude on the basis of their coat development also had abnormal thymuses, a few survivors were examined histologically. We found the typical picture of thymic dysplasia with cystic and tubular structures among irregularly arranged epithelial-like cells surrounded by connective tissue. Spleen and lymph nodes were found depleted of lymphoid cells in the thymus-dependent areas^{9,10}. To measure functional impairment of the T cell system in nude, *Mx*-bearing mice, use was made of the fact that formation of haemagglutination-inhibiting (HAI) antibodies is a T cell dependent function¹². Two and three weeks after virus challenge, individual surviving nude and non-nude littermates were bled and the titres of HAI were determined. Figure 1 shows the results: nude mice surviving virus challenge had significantly lower antibody titres than similar non-nude littermates. The same difference was also revealed with antibodies to the complement-fixing nucleoprotein

Location of nuclear proteins on the chromosomes of newt oocytes

In eukaryote cells chromosomal proteins are responsible for the organisational state of the DNA and the control of genetic expression, therefore knowledge of their location is an essential prerequisite for understanding chromosome function. Cytological localisation of chromosomal proteins is feasible using cells with giant chromosomes such as the oocytes of the newt *Triturus cristatus carnifex* where there are clearly defined regions active in RNA transcription (the loops) and regions containing most (>95%) of the DNA in a condensed state (the chromomeres)¹. There are two main classes of protein associated with chromosomes: histones, which are generally considered to be complexed with the sugar-phosphate backbone of the DNA²; and nonbasic proteins which are constituents of metabolically active chromatin³.

We extracted the nonbasic proteins from ribonucleoprotein (RNP) particles which are released from the chromosomes into the nucleoplasm⁴. These nonbasic proteins have been shown previously⁵ to comprise a heterogeneous size distribution of polypeptides. Here the polypeptides were separated on a preparative scale by column chromatography and injected into rabbits to stimulate antibody production. Histone protein was extracted from newt liver chromatin and was also used to produce antibodies. By treating chromosome preparations with

fluorescein-conjugated antibodies the chromosomal sites of the various proteins were determined.

Nuclear RNP particles were isolated from homogenates of newt oocytes as described previously^{4,5}. The final step in purification was the collection of the peak fraction from a 30–50% (w/v) sucrose gradient. At all stages in isolation, solutions contained 5 mM 2-mercaptoethanol to prevent protein aggregation⁶. The RNP was solubilised in SDS-buffer (0.1% sodium dodecyl sulphate; 10 mM Tris-HCl, pH 7.4; 10 mM 2-mercaptoethanol; 50 mM NaCl) and dialysed for 4 h against

Fig. 1 Separation of nuclear RNP proteins by column chromatography. An 0.5 ml solution of SDS-solubilised protein was applied to a 56 cm column of Sephadex G-200 Superfine gel and eluted with SDS-buffer. The eluted material was divided into five fractions as shown on the A_{280} profile. At the void volume of the column (V_0) there was occasionally elution of contaminating RNA. The peak assigned as fraction 5 was not present in all preparations (dotted line).

this buffer. The solubilised RNP complex was centrifuged at 95,000g for 16 h to remove RNA by pelleting. To separate the RNP proteins on a molecular weight basis a 0.5 ml sample was eluted through a column of Sephadex G-200 gel with SDS-buffer. The elution profile of absorbance at 280 nm is shown in Fig. 1. Resolution of peaks was not as good as was obtained by SDS-acrylamide gel electrophoresis but large amounts of protein could easily be separated. The eluted protein was divided into five fractions each of which was concentrated to 0.5 ml by pressure dialysis. The complexity of protein content in each

fraction was analysed by SDS-acrylamide electrophoresis. These were compared with electropherograms of total RNP protein and of total histone (Fig. 2). Of the 13 main bands in the total RNP extract, between two and four bands were contained in each of the five gel-filtration fractions and distributed between these fractions in groups of decreasing molecular weight (see also Table 1). The separation of the proteins by gel filtration was judged to be satisfactory.

As antigen sources, 0.5 ml samples of total RNP protein, fractionated RNP proteins and total histone were each incorporated into multiple emulsions⁷ and injected into different rabbits. Similar samples were injected into different rabbits on three separate occasions to eliminate any anomalous effect due to a particular animal. After a minimum of 60 d the rabbits were bled and the sera were prepared as described previously⁸.

The various antisera were reacted with chromosomes as follows. Lampbrush chromosomes were prepared from newt oocyte nuclei⁹ and firmly attached to the surfaces of coverslips by centrifugation through Tris-buffered saline⁴, at pH 7.8, to obtain maximum transmission of fluorescence. The chromosome preparations were treated with various dilutions of antisera in buffered saline for 30 min, washed in buffer for 1 h, placed in fluorescein-conjugated sheep anti-rabbit antibody solution (Wellcome Reagents Ltd) at a dilution of 1:100 and again washed

Fig. 2 SDS-acrylamide gel electrophoresis of solubilised proteins. *a*, Total nuclear RNP protein; *b–f*, fractions 1–5 derived by gel filtration (Fig. 1); *g*, newt liver histones (kindly supplied by Dr D. B. Malcolm). 20 μ l samples were applied to 7% polyacrylamide gels containing 0.1% SDS and 0.1 M phosphate buffer, pH 7.1. Electrophoresis was at 10 mA per tube until the buffer front had migrated 6–7 cm. The gels were fixed and stained with Coomassie blue.

Table 1 Characteristics of antisera produced against chromosomal proteins

Antiserum produced against	Molecular weights of main components used as antigen	Titre (greatest dilution giving a fluorescent reaction)	Specificity of reaction with lampbrush chromosomes
Total nonbasic protein	155,000–17,000 (13 bands)	1 : 2,500	With all loops and with chromomeres to a lesser extent
Fraction 1	135,000 125,000 90,000 50,000	1 : 1,750	With all loops
Fraction 2	65,000 50,000	1 : 1,750	With all loops
Fraction 3	65,000 50,000 35,000	1 : 2,500	With only 10 pairs of loops
Fraction 4	35,000 20,000	1 : 1,750	With all loops and with chromomeres to a lesser extent
Fraction 5	20,000 17,000	1 : 1,500	Mainly with chromomeres
Total histone	20,000 16,000	1 : 2,500	With chromomeres
Normal serum	—	1 : 500	With all structures

in buffer. The chromosomes were located by phase contrast microscopy and then the fluorescent reaction was observed in a beam of ultraviolet light using the appropriate exciter and barrier filters.

Antiserum produced against the extract of nonbasic proteins reacted specifically with the chromosomes and more intensely with the loops than with the chromomeres. The antiserum produced against histone reacted primarily with the chromomeres (Fig. 3d). Control preparations using normal rabbit serum reacted nonspecifically with all structures, nucleoli as well as chromosomes, but only at a relatively high serum concentration. The greatest serum dilution at which a fluorescent reaction could be obtained (see Table 1) was routinely used to avoid cross reaction and nonspecific effects. There was some reaction with the loops with anti-histone serum but this is most likely to result from contamination of histone extract with some nonbasic protein. In fact a few minor bands of high molecular weight protein could be seen on the electropherogram (Fig. 2). Low concentrations of histones may well be present in the loops but the technique used here is probably not sensitive enough to detect these.

Fig. 3 Phase contrast and fluorescence photomicrographs showing location and specificity of reaction of fluorescein-conjugated antibodies with lampbrush chromosomes. *a*, Antiserum produced against RNP-protein fraction 2 at a concentration of 1:1,000; *b* and *c*, antiserum against fraction 3 at a concentration of 1:1,250; *d*, antiserum against histone at a concentration of 1:1,000. The photomicrographs were taken on Ilford FP4 (1 s exposure for phase; 2.5 min exposure for fluorescence) and developed in Paterson's Acutol. The bars represent 10 μ m.

Of the protein fractions derived from solubilised RNP fractions 1, 2 and 4 stimulated antibodies which reacted specifically with all the chromosome loops (Fig. 3a), that is, one or more of the proteins present in these fractions were common to the RNP matrix of all loops. As a result of the distribution of different polypeptides between these fractions (see Fig. 1 and Table 1) at least two different proteins are common to all loops. Antibodies produced against fraction 4 showed some cross reaction with the chromomeres. Furthermore, antibodies against fraction 5 reacted specifically with the chromomeric axis. Fraction 5 gave a very similar banding pattern on SDS-acrylamide gels to that of histone (Fig. 2). Because this fraction was not present in all RNP protein extracts (Fig. 1) fraction 5 was judged to be contaminating histone probably as a result of excessive homogenisation of the oocytes.

The most interesting and unexpected result was given by antiserum produced against fraction 3. This antiserum reacted with the proteins associated with only certain loops—approximately 10 loop pairs in each chromosome complement. These loops did not have any peculiar morphology and could not be

identified before the fluorescent reaction (Fig. 3b and c). As far as can be discerned the same loops give this specific reaction in all chromosome preparations and are randomly distributed. Because the whole length of spatially isolated loops gives a specific reaction this is conclusive evidence of the integrity of the loop structure, that is, the lampbrush loop is a functional unit. Evidence that the loop is a unit of transcription will be reported later (J.S., unpublished work). The protein which is the main component of fraction 3 and which probably elicits the specific loop reaction has a molecular weight of approximately 35,000.

Thus histones are present primarily in the regions of condensed DNA (chromomeres) in lampbrush chromosomes (previously shown to contain basic protein by staining¹⁰ while RNP-derived nonbasic proteins are restricted to the loops. The implications of the high protein content of nuclear RNP remains unknown. Preliminary evidence suggests that various types of enzymic activity are present, specifically the ability to polymerise ribonucleotide triphosphates and to cleave large nuclear RNA into smaller fragments. Homoribonucleotide polymerases¹¹ and endonuclease¹² have already been reported to be present in mammalian RNP particles. Obviously enzymes concerned with the processing of primary transcript RNA can only account for a very small amount of protein which may even not be visible in gel electropherograms. A secondary RNP formed during oocyte maturation has been isolated and has been shown to have a similar protein constitution to the RNP described here. Results pertaining to the protein content of the different RNP products at various stages in the processing of RNA transcripts will be reported later.

We thank Dr D. B. Malcolm for supplying the histones and Professor H. G. Callan for critically reading the manuscript.

Erratum

In the article "Deterioration of high school students' attitudes to physics" by P. L. Gardner (*Nature*, **250**, 465; 1974), the following corrections should be made to the 3rd paragraph: line 5, for 4 yr read 2 yr; lines 10-11 should read "in coeducational State high schools in moderately affluent suburban areas of Melbourne."

matters arising

Geomorphological dating of cave openings in South Africa

In a recent article in *Nature*¹ Partridge dates South African hominid sites with remarkable precision by relating them to retreat of cyclic nickpoints. The soundness of his analysis and results depends on the validity of his geomorphological framework, the date of 20 Myr assigned to the inception of his cyclic nickpoints and his method.

The framework is well known and provides for the existence of identifiable remnants of 'Gondwana', 'post-Gondwana', 'African' and later cyclic surfaces of former continental extent². The dating and correlation of erosion surfaces over wide areas of Africa with quite different climatic and tectonic histories rest, however, on shaky grounds³. Moreover, results of recent work connected with the South African oil search on land and offshore contradict the framework in many material respects. Lack of space makes it impossible for me to elaborate here, but, as an example, the Paleogene, during which the African surface on land reputedly stood so low that the rivers were sediment starved⁴, saw the most rapid deposition off the Natal coast from the mid-Cretaceous onwards.

The dating of 20 Myr for the inception of the 'Post African 1' cyclic nickpoint, based on transgressive sediments above an unconformity at Uloa, Natal⁵, is taken as factual. The correlation of transgressive coastal sequences with incision on land is debatable, as it presupposes rather special conditions; but if we accept that the sediments above the unconformity could record the first incision of the 'African' surface, the figure may have to be doubled: in the J (c)-1 well, drilled 24 km off Stanger, the unconformity and 'Pecten Bed' are clearly identifiable, but the age is early Oligocene⁶. Relationships at Uloa, on which so much has been based, are representative of one stand of a slowly migrating shoreline.

Briefly, Partridge's method involves the calculation of mean rates of nickpoint recession in respect of each site, which are then plotted in relation to the midpoints of the segments affected by incision. He assumes that nickpoint migration was subject to linear decline culminating in zero at the stream sources, and apparently reads off the rates of migration at the hominid sites from the graph in Fig. 2. He admits

that the assumption is erroneous, but maintains that the errors of the linear interpolation technique are greatly reduced due to the close proximity of the sites to the headwaters. He thus makes an assumption that seems to be basic to his argument and calculations, admits that it is erroneous, but brushes away any possible reservations by implying that migration rates near the sites were so low that they would have been little affected by what happened downstream anyway.

Recognition of small nickpoints so far upstream as expressions of an ancient coastal event cannot be an easy exercise in a region with numerous nickpoints clearly attributable to differential rock resistance, warping, and so forth. Moreover, a method based on nickpoint recession cannot be applicable to a major basin such as the Orange, where great differences in gradient and channel characteristics reflect the extreme variations in lithology. The present regime illustrates the influence of climate: below Prieska the flow probably decreases at normal times downstream, and nickpoint recession rates would presumably not have decreased upstream under comparable past climates. My gravest criticism, however, is that the implications of differential nickpoint recession up a main stream and its tributaries are ignored. Thus the Orange, the Vaal, the Harts and a small tributary are lumped together, although they are clearly not amenable to treatment as a single unit; this procedure presupposes that recession rates are mainly dependent on distances of watersheds and nickpoints from the main drainage outlet to the ocean, and not on conditions along the stream courses themselves.

Partridge's methods and basic assumptions are of doubtful scientific validity, and his datings can only serve to confuse and mislead South African anthropologists.

DR PARTRIDGE REPLIES: Dr de Swardt's comments, although relevant to the technique and results reported in my article, reflect fundamental misconceptions as well as lack of familiarity with recent geomorphological research in South Africa. It would therefore be unprofitable to take issue with him point for point, though I should like to refute certain statements of his which have direct bearing on my argument.

(1) I claimed no "remarkable precision" for my estimates for the date of first cave opening at the various hominid sites. My results were presented cautiously and with deference to limitations in accuracy imposed by availability of data for the construction of the nickpoint migration graphs, and the resulting possibility of small scale fluctuations between observation points.

(2) The geomorphological framework which de Swardt calls to question is firmly based on scientific observation and measurement, and does not rely on the unsupported views of any one worker. In particular, Professor L. C. King has never claimed that all of the cyclic surfaces referred to by de Swardt were of former continental extent. This is a totally unreasonable proposition, and was certainly not applied in the context of my work. Indeed, the study of such surfaces in southern Africa has revealed that some are represented over limited areas, others have been partially planed and most have been subject to post-formational warping. All these factors have been subjected to detailed analysis (see references in my original article), and the results have been taken into account in the application of my technique.

(3) There is no contradiction of the geomorphological framework which I applied in the records of offshore oil prospecting cited by de Swardt. Various workers, including King, have recorded sedimentation of the continental shelf, dating from mid-Cretaceous to early Tertiary times¹⁻³, which can

be referred to onshore incision in the African erosion cycle. These offshore results merely add to the overwhelming body of evidence in support of the framework which de Swardt wishes to discredit.

(4) In assessing the date of inception of the Post-African I erosion cycle, the age of littoral sediments immediately overlying the Post-African I planation surface must be conclusive. Where such sediments have been preserved, not only at Uloa, but along considerable stretches of the South African coast between East London and Saldanha Bay, their age has proved to be Miocene³. Simple palaeontological principles do not permit that the Oligocene "Pecten Bed" identified 24 km offshore during drilling operations is the same biostratigraphical unit as that of Uloa, since both the shark and Pecten fauna at the latter locality have been confidently placed within the Miocene on the basis of reliable evidence^{4,5}. The 20 Myr date for the inception of the Post-African I incision can therefore be accepted with confidence. Relationships along considerable stretches of the coast do not indicate a slowly migrating shoreline, but several phases of transgression during the Tertiary^{3,6}.

(5) A small margin of error in my assessment of nickpoint migration rates cannot be avoided, as the linear assumption provides for a mean representation, which cannot readily be refined, as the affects of some variables are impossible to measure. This is a potential source of some inaccuracy, but can by no stretch of argument be regarded as fatal to the technique. The absolute range of possible inaccuracies must, of necessity, decrease towards the watershed origin. This range is considered to be sufficiently small to permit the technique to be used to derive general orders of age and a relative sequence of dates for cave opening—all that I originally claimed for my results.

(6) Numerous erosional nickpoints in South Africa can be recognised through careful fieldwork. Their cyclic associations are not difficult to determine through the application of careful morphometric and statistical analyses such as formed the basis for my article. Erosional nickpoints are clearly distinguishable from those of lithological or local tectonic origin.

(7) Decline in nickpoint migration rates upstream is by no means exclusively a function of diminishing discharge. Owing to large scale Plio-Pleistocene upwarping of the South African coastal margins, many rivers show substantially steeper gradients along their lower courses than in higher reaches; for example, between the Orange River mouth and Prieska,

the mean channel gradient is 0.9 m km⁻¹; between Prieska and Buxton on the Harts River the gradient is 0.4 m km⁻¹.

(8) Variations in nickpoint migration rates between trunk and tributary channels are, indeed, taken into account in my analysis, since my measurements are related to the actual channel segments concerned. Varying conditions along such segments have naturally affected the present positions of the nickpoints which have migrated along them, upon which my graphs are based. The limited inaccuracies which may result from small-scale fluctuations between observation points have been considered.

(9) The validity of my method and assumptions is further confirmed by two age estimates based on entirely different techniques. My estimate of 4.8 Myr for the 61 m terrace of the Vaal River at Windsorton⁷, based on the same methods used to estimate dates of first cave opening, is generally confirmed by the presence at this locality of elephant remains which existed some 4 Myr ago in the East African potassium-argon chronology⁸. Moreover, Butzer⁹, in a lengthy analysis to be published in December, has independently arrived at a maximum age estimate almost identical to my own for the Taung hominid deposit.

Ascorbic acid and nitrosamine

SIR—Edgar¹ has proposed that ascorbic acid might inhibit the carcinogenic action of nitrosamines and other carcinogens that may act by alkylation. The rationale was that ascorbate might be alkylated *in vivo* before the carcinogens can react with cell macromolecules. The experimental basis for Edgar's thesis was that statement by Kamm *et al.*² that ascorbate inhibited the liver necrosis induced by dimethyl-

nitrosamine (DMN). This statement, however, was presented without experimental details and was subsequently withdrawn³.

The main concern of the study by Kamm *et al.* was the inhibition by ascorbate of the liver toxicity induced by oral administration of aminopyrine plus nitrite. This study followed our report in 1972 suggesting, on the basis of *in vitro* experiments, that ascorbate might be used to block *in vivo* formation of N-nitroso compounds from nitrosatable chemicals (for example, drugs), since ascorbate efficiently reduces nitrate⁴. Subsequently, the report of Kamm *et al.*² appeared. Greenblatt⁵ found similar results in mice to those of Kamm *et al.*, but stated that ascorbate did not affect DMN toxicity. We found that ascorbate prevented liver damage from gavage of dimethylamine plus nitrate to rats and, from experiments presented in detail, that ascorbate did not significantly affect the production by DMN of liver necrosis and elevated serum transaminase levels⁶. Ascorbate did not affect transplacental carcinogenesis in rats by ethylnitrosourea, but inhibited carcinogenesis by ethylurea plus nitrite⁷.

We are concerned that our original suggestion should not be extended without basis to the hypothesis that ascorbate might have a much wider inhibitory action on carcinogens. The interesting suggestion of Edgar is not supported by the results reviewed here, which were mostly made public after Edgar's paper was submitted.

reviews

Immunoglobulins

The Antigens. Vol. 1. Edited by Michael Sela. Pp. xiii+573. (Academic: New York and London, January 1974.) \$31; £14.90.

THE appearance of a multivolume work about any topic is a sign that the subject has now become part of the body of accepted scientific knowledge. A period of rapid progress is coming to an end and there is a sufficient volume of fact and theory to form the basis of undergraduate courses as well as to be an essential part of the background of all scientists working in related fields. In biochemistry, proteins were the first subject to receive this accolade some twenty years ago followed quickly by enzymes, nucleic acids and many others. The aim was to present research workers, teachers and advanced students with a rather full account of the field and on the whole they have served a useful purpose, though of necessity they have been a year or two out of date by the time they reached the libraries. Now it is the turn of immunochemistry, or as some would have it, molecular immunology. How does it match up?

The first glance is disconcerting as volume 1 of *The Antigens* contains four chapters on antibodies, one general chapter on protein evolution and only two on antigens. Volume 2, of which the contents are listed, will have three chapters, each on antibodies and antigens. This is perhaps not important, as any potential reader will be well aware that it is hardly possible to write of antigens without extensive reference to antibodies and indeed much of the progress in knowledge of antibody structure, genetics and synthesis has come from study of their antigenic properties, but it would have been helpful if the title had given a better guide to the contents.

The antigens chosen for discussion in this volume are nucleic acids by Dr David Stöller and enzymes by Dr Ruth Arnon. The former are difficult to handle as injection of purified nucleic acids into an animal of different species rarely gives rise to a significant immune response and specific antibodies are found only when protein-nucleic acid complexes are used; that is the nucleic acids are behaving as large molecular weight haptens. Nevertheless, in recent years satisfactory antisera have been obtained (and have been found to

occur spontaneously in pathological conditions) and have been used effectively in investigations of the structure and function of nucleic acids in cell and subcellular fractions and a useful summary of the work is given here. Enzymes are much more easy to handle as antigens and Dr Arnon has led much of the work directed to using specific antisera to gain information about their structure and catalytic activity. This has proved a valuable adjunct to the very extensive studies of enzymes by protein chemists, X-ray crystallographers, enzymologists and all the others and, over an increasing range, has complemented and confirmed knowledge of these key molecules.

Immunoglobulins are the major subject of this book, about a quarter of which is given to their structure, and rather less space given in turn to the immunoglobulin allotypes, phylogeny of immunoglobulin and the chemistry and biology of immunoglobulin E. Dr Gall has given a good account of the chemical structure which is now well understood, but it is unfortunate that the article was written just too early to include the recent work of the X-ray crystallographers which is clarifying the nature of the combining site and other topics which he discusses. Allotypes have long had a fascination for some of us, particularly the *a* locus allotypes of the rabbit which remain the odd man out in most of the work on these allelic variants of the immunoglobulins. These investigations have contributed greatly to knowledge of their genetic origin and the conviction remains that when their behaviour is fully understood it will give a much clearer understanding of the source of the multiplicity of form of immunoglobulins. This chapter by Dr Rose Mage and colleagues has got all the facts and some of the speculation well presented. Dr Ishizaka has given perhaps the most personal account in his chapter on IgE, the minor immunoglobulin class responsible for immediate type hypersensitivity and apparently of major importance in the immune defence of the host against a variety of parasites. Of obvious clinical importance, this is a field where the myeloma proteins, for a long time the only source of large amounts of homogeneous immunoglobulin, have been of exceptional importance.

A general chapter on protein evolution by Dr Norman Arnheim serves as an introduction to the phylogeny of

immunoglobulins by Drs Kubo, Zimmerman and Grey. This is another way to try and understand the genetic origin of the complexity of immunoglobulin structure and, although the contributions from this approach have not so far been of major importance, it is well worthwhile from this point of view as well as for its intrinsic interest in biology. The transition from invertebrates to vertebrates seems to have been the most important point in the development of a specific immune response and much of the work described centres on the immunoglobulins of the lower vertebrates. No evidence has, however, been found so far for the original gene product of 11-12,000 molecular weight from which the immunoglobulins of present vertebrates are believed to have been derived by gene duplication.

The chapters are reasonably balanced in content, but their arrangement seems arbitrary. Together with the second volume a fair coverage is given of the more biochemical aspects of immunology, though there are surprising omissions such as the absence of any discussion of immunoglobulin biosynthesis. Perhaps with the title of 'The Antigens' this is not surprising, but with more than half the space given to immunoglobulins, biosynthesis would seem a stronger candidate for inclusion than, say, the individual classes of immunoglobulin. The editor's difficulties are apparent and it is perhaps questionable whether these multivolume works are the most effective way of summarising present information. The alternative of an advanced textbook giving a briefer but more integrated survey and supplemented, for the enthusiast, by the annual volumes of reviews on specialised topics has much to commend it. There is no doubt room for both and this volume and its successor should be a useful source of reference for some time to come.

R. R. PORTER

Betas and muons

Beta Decay and Muon Capture. By Masato Morita. Pp. xi+361. (Benjamin: Reading, Massachusetts and London, March 1974.) \$19.50.

THIS is a curious book, though it will probably be very useful to a specialised audience. It has grown from a course of postgraduate lectures given at the University of Osaka. Judging by the

notation and the balance of the material, the course was written in the early sixties and has not changed its shape since then. The first five chapters, which occupy half of the main text, give an introduction to weak interactions. There is a great deal of historical detail on the Fermi and Gamow-Teller theories. Parity non-conservation is treated at length, as if it were a brand new phenomenon, before a long and circumstantial chapter on the V-A theory. The weak interactions of elementary particles are given a reasonable amount of space, but with an alarming vagueness. This is certainly not the place to read about the Cabibbo theory, for instance. Its results are mentioned, but after a page and a half of introduction the author announces that "we do not have space to introduce the SU3 computation". Surely he could introduce Clebsch-Gordan coefficients, by analogy with SU2, to justify the precise numerical predictions of the theory which he tabulates.

The second half of the main text is devoted to the chief business of the book, a review of beta decay and muon capture as tools for nuclear structure physics. The presentation is pedestrian, but the details of individual experiments are given at unusual length. Although most of the reference lists stop in about 1969, there is a chapter which deals with more recent developments, such as the investigation of second class currents in the transitions of mirror nuclei.

Because of the detail in the later chapters, and because of the patiently long-winded explanations of many technical points, this book should be very useful to experimental students of nuclear physics. But they should come to it after a simple course on the weak interactions of elementary particles, based for instance on some of the excellent reports published by CERN, Geneva (Cabibbo and Veltman: CERN 65-30; and J. S. Bell: CERN 72-4).

D. J. MILLER

Crust of the Earth

Structural Geomorphology. By J. Tricart. Translated by S. H. Beaver and E. Derbyshire. Pp. xiii+305. (Geographies for Advanced Study.) (Longman: London, April 1974.) £4.75.

PROFESSOR TRICART'S book, published in France in 1968, has been admirably translated by two geographers from the University of Keele. It is intended not only for students taking a first degree in geography but also for specialists in the "cognate disciplines" of geology, pedology, ecology and planning. The

book is built round the premise, stated on the first page of the introduction, that the surface features of the lithosphere have been moulded by the interaction of internal and external forces at work in the Earth's crust and the author recognises a close relationship between characteristic landforms and large-scale crustal structures. The first chapter deals with the distinctions between continents and oceans, the second with geosynclines and fold belts, the third with platform areas and the final chapter with faults and volcanoes. Stress is laid on the fact that landscapes evolve over long periods.

This scheme of treatment, together with Professor Tricart's excellent aphorism (page 22) that "nature herself is a unified whole" raises the hope that the book, by bringing geological and geographical thinking to bear on a subject involving both disciplines, may illuminate the whole field of geomorphology. Where details are concerned, the book does indeed provide many clear and well illustrated examples of the relationship between structure and landform.

Further reading, however, raises serious doubts about the geological treatment. The author's views of crustal evolution have much in common with those of Soviet geologists who discount the possibility that large-scale horizontal displacements of continents have taken place during the past few hundred million years. This view is seldom expressed today in English or American works and a reasoned exposition of it might have been welcome. But it is disconcerting to find no discussion of the evidence concerning seafloor spreading (the mid-Atlantic ridge is referred to only once, on page 36, as a structure "somewhat similar to an island arc") and even more so to find on page 45 the statement that "despite the precision of the techniques, no measurements yet made have shown the slightest signs of change in the relative positions of Europe and North America, which should have occurred if the two continents are drifting apart".

This statement, made without any qualification, is the more surprising in that classic palaeomagnetic studies by Runcorn, Tarling and others are cited in the bibliography. Errors of fact are not uncommon: for example, the Moho, though defined as the base of the crust on page 41, is referred to on the next page as a discontinuity within the crust: the *schistes lustrés* are described as a flysch facies. More important, perhaps, from a student's point of view is the lack of a stratigraphical table or any other data from which he can discover the relative ages of the geological systems mentioned, the absence of any account of landforms associated

with depositional processes, and the cursory treatment meted out to rift valleys. Since the geological aspect is fundamental to the author's approach, I feel that defects of this kind undermine the whole structure of the book.

J. WATSON

Excited molecules

Excited States. Vol. 1 Edited by Edward C. Lim. Pp. xii+347. (Academic: New York and London, January 1974.) \$24.50; £11.75.

INTEREST in the structure of electronically excited species in the gas phase has been growing apace in the last two or three decades. A discussion of the Faraday Society in 1963, on just that subject, was an undoubted success. Somewhat earlier (1955) had come a text by Laidler on *The Chemical Kinetics of Excited States*, and Reid's book (1957), *Excited States in Chemistry and Biology*, was a stimulating early work.

The present volume, it might be argued, is not one but six. Certainly, its six chapters differ considerably in subject matter. The first, by G. Wile Robinson, deals with radiationless transitions, whereas the remaining five deal with topics that involve emission or absorption of radiation. Robinson's chapter is much the most readable of the six. The second chapter, by M. A. El-Sayed, contains a comprehensive review of phosphorescence microwave double resonance spectroscopy (PMDR). It seems from this article that there will be a considerable increase in the number of abbreviations that infest the literature.

The third chapter, by Robin M. Hochstrasser and Paras N. Prasad, deals with optical spectra and relaxation in molecular solids. It outlines various aspects of the electronic spectra of solids (molecular crystals and mineral crystals) and contains detailed discussion on phonon interactions that have not previously been treated in detail. The fourth chapter, by Wolfgang Liplay, is an excellent account of the determination of dipole moments and polarisabilities of molecules in excited electronic states. The fifth chapter, by C. J. Selisker, O. S. Khalil and S. P. McGlynn, treats the luminescence of polar aromatic molecules; and the sixth, by A. J. Duben, L. Goodman and M. Koyanagi, deals with interstate interactions in aromatic aldehydes and ketones.

The book is very well produced. I found perhaps half-a-dozen printer's errors, none of them of great import. Further volumes are planned.

A. D. WALSH

Fact and language

Linguistics and Information Science. By Karen Sparck Jones and Martin Kay. Pp. xii+244. (Library and Information Science Series.) (Academic: New York and London, January 1974.) \$14.50; £6.80.

THIS book is a state-of-the-art survey on the use of linguistic theories and techniques in information retrieval. The emphasis is on automated methods; that is, on linguistic theories that have been (or could be) used to develop computational methods of analysing language, and on their use in automated information retrieval systems. The survey concentrates on the literature of 1965–1970.

The authors first take a bird's-eye view of activity in the separate fields of information retrieval and linguistics, and then consider the particular aspects of information retrieval which have an apparent linguistic content. The meat of the book comes in two chapters on syntax and semantics respectively, where a detailed analysis of the present state of linguistic theory is followed by a discussion of how this theory has been, or might be, applied to information retrieval. There is a further section on fact retrieval.

The authors lean fairly heavily on an analysis of the retrieval process which identifies three stages: informal interpretation of the document, formal representation of this interpretation, and manipulation of the representation in searching. One can imagine other views of the process (indeed, they mention another)—not necessarily better ones, but ones which emphasise other aspects. In some instances the authors are restricted by their particular approach. For example, they point out quite rightly that most comparative experiments that have been carried out with index descriptions using syntax seem to show that this syntax is not particularly useful in retrieval. But they do not consider one possibility: that the fact that the indexer (man or machine) has to formulate the description in a syntactically coherent form may influence his choice of terms, and hence may affect retrieval performance even if the terms are searched in a postcoordinate manner, ignoring syntax.

But this argument serves to reinforce one of the main conclusions of the book: that there is a lack of suitable theories of information retrieval which would indicate where linguistic theories might be of use. Overall, the conclusions are somewhat negative: both fields have to develop further before the one is likely to be a major contributor to the other. Indeed, there is some doubt that this will ever happen; but the authors argue

persuasively that there are still plenty of possibilities.

The book performs its function as a survey very well, with a surprisingly good international coverage. It is coherent and well thought out, and also well written. The production is decidedly cheap-looking (yellow paper, a number of misprints, badly aligned type and uneven type density). But in content the book is a valuable contribution to the literature, which should help to bring order to a somewhat fragmented field. S. E. ROBERTSON

Why plans go awry

Planning and Budgeting in Poor Countries. By Naomi Caiden and Aaron Wildavsky. Pp. xvii+371. (Comparative Studies in Behavioural Science.) (Wiley: New York and London, March 1974.) £8.40.

A MAIN theme of this book had been anticipated by Bert Brecht in the *Threepenny Opera*. Freely translated, the song goes something like this:

Well, go and make a plan!

Seek where matrices lurk

Then go and make a second plan,

Neither of them will work.

Or, in the words of the Nepalese planner, summarising the experience of his country: "Try one form of organization; no result. Try something else; no result. The result is always the same" (Page 216).

The two authors of this book are political scientists who have covered more than 80 poor countries with questionnaires and interviews in order to examine government planning and budgeting and to recommend reforms. Their work reflects the disenchantment with planning.

Some of the criticisms of plans are ambitious, abstract, irrelevant and unrealistic miss the point. The purpose of formal models is to trace the indirect effects of alternative policies. Things often turn out differently in the second and third round from the intentions of the first. First-round socialism may turn into third-round monopoly capitalism. Particularly but not only in poor countries good causes tend to be turned into rackets. The reason why planning has failed, where it has failed, is not that it uses abstract models and traces interdependence between variables, but that it has sometimes been pseudo-planning, confined to a ceremonial superstructure, without being geared to where the action is.

The authors argue for the central importance of the annual budget. Though it is obviously true that no plan can be implemented unless it is integrated into the annual budget, there is a danger of mistaking a nec-

essary, though minor, condition for the strategic one. Budgets are, at best, annual public expenditure plans. A focus on fiscal magnitudes, though essential for proper public accounting, obscures and evades the real activities. Links between fiscal (or even financial) expenditures and results are tenuous, especially in underdeveloped countries. There are no fixed coefficients between money expenditure and land reform, population policy, incomes policy, education, public health, nutrition. Foreign exchange budgeting, manpower budgeting, raw material budgeting are just as important as fiscal budgeting and even they do not exhaust the range of necessary policies. Proper public accounting is necessary to ensure, negatively, that public money is not spent extravagantly or corruptly, but it cannot ensure, positively, that it is spent according to social priorities and that the necessary complementary actions are taken. Budgeting is to planning what bookkeeping is to business management: without it, management is impossible; but with the best book-keeper in the world, a firm can go bankrupt. These points are not enough stressed by the authors, who see the plan essentially as a many-year public capital budget.

Much is made of the need for redundancy. In a piece of exquisite jargon, the authors write: "Broadly speaking, we can regard social poverty as a lack of functional redundancy" (Page 49). But there is a vast difference between reserves (which serve a purpose) and redundancies. A more analytical and quantitative approach would have made the distinction clear. It is now well known that in poor societies, not only unskilled labour, but also capital and technically trained professional manpower are redundant: but, alas, they are not reserves.

The authors make a large number of entirely fair and commonsensical criticisms of planning. "If we were asked to design a mechanism for decisions to maximise every known disability and minimise any possible advantage of poor countries, we could hardly do better than comprehensive, multi-sectoral planning" (Page 293). The need for unavailable information, for political stability, for consistent aims are cited as unattainable conditions. But perhaps the most serious criticism of planning is omitted, viz. that its very success, measured by coherence and consistency, becomes an obstacle to adaptation and innovation. Plans introduce an additional rigidity into societies already inflexible. Plans, for this reason, in spite of their declared intentions, are elements strengthening conservatism.

The conclusion is not, however, reliance on *laissez-faire* and the free play

of market forces. The authors rightly point to the need for a combination of contingency planning, continuous budgeting and rolling planning, so that there can be adequate and speedy responses and adaptations to unforeseen events, both favourable and unfavourable.

The authors treat planners and planning as part of the social and political environment which they are supposed to plan. Planning the planners is not an invitation to an infinite regress but a reminder that there must be continuous mutual adaptation between plan objectives and social constraints.

PAUL STREETEN

Steroid receptors

Steroid-Cell Interactions. By R. J. B. King and W. I. P. Mainwaring. Pp. 440. (Butterworth: London, February 1974.) £10.

JENSEN and Jacobsen showed in 1962 that tissues such as the uterus and vagina, which are responsive to oestrogens, will retain administered oestradiol to a greater extent than non-responsive tissues and that this retention was due to the presence in the responsive tissues of specific receptor proteins. Since then the receptor hypothesis has been extended to many other hormones and the interaction between hormone and receptor is considered to be one of the links in the chain of events by which the hormone exerts its biological action. This concept has thus become of interest to molecular biologists as well as endocrinologists. The increased interest in this topic over the past five to six years has led to its discussion in numerous reviews and symposia; so what are the advantages of reading this monograph over consulting the reviews? Undoubtedly in the chapters reviewing the interaction of the various steroid hormones with the cell receptors there is more detail than found in most of the reviews. By far the main advantage, however, is the account of both the theoretical and practical background to the topic contained in the first two chapters on "Physicochemical Considerations of Steroid-Receptor Interactions" and "Methods Used to Study Steroid-Tissue Receptor Interactions" and the chapter giving a readable account of the molecular biological aspects of steroid-receptor interaction.

The title is slightly misleading since the monograph is mainly concerned with interactions involving receptors. Both androgens and oestrogens affect tissues or metabolic processes in which receptors have not yet been shown to be involved and this might suggest that there are other kinds of steroid-cell interactions. Many examples are

quoted by the authors. Androgens are anabolic but androgen receptors in skeletal muscle are difficult to identify nor has 5 α -reductase activity been demonstrated in the muscle of many species. Androgens stimulate both RNA and protein synthesis in liver but androgen receptors have not been identified in this tissue although it seems to contain oestrogen receptors. Normal breast tissue, which is influenced by oestrogens, accumulates oestradiol but does not seem to contain oestrogen receptors whereas breast tumours do. Little attention is paid to the interaction between the hormones in the tissues (uterus for example seems to contain an androgen receptor in addition to oestrogen and progesterone receptors), nor is the effect of other modifying influences on the hormones considered. This might be particularly important regarding events in the pituitary and brain. Conversion of testosterone to dihydrotestosterone seems not to be necessary for all biological activities of testosterone. Indeed some biological effects of testosterone seem to be produced by its conversion to oestrogen whereas dihydrotestosterone is not aromatised in this way. Until more knowledge is available it might be better to draw a distinction between androgen-sensitive tissues and androgen-dependent ones.

The authors point out the remarkable similarity of the different receptor proteins from different tissues. These similarities are deduced from current physicochemical data and it will be of interest to see whether they are upheld on further examination. Evidence that hormone binding correlates with hormone activity is reviewed. In respect of oestrogens and progesterone the evidence is quite good even though knowledge is limited. For androgens the situation is complicated by the extensive metabolism undergone by testosterone in the target organs and the possibility that the various metabolites may have different biological activities.

The monograph is well arranged and the newcomer to the field will have no difficulty in finding what he wants. In an attempt to bridge the gap between the writing of the book and its publication a summary of current literature is included. Whereas some of the chapters contain general summaries which are useful, others do not. I feel that the brief chapter on clinical and immunological aspects of steroid binding is superfluous to the main theme of the book. It will be a handy reference book to all investigators in this field and because of the amount of time it will save, it should be greatly appreciated by research students starting work in the area.

K. FOTHERBY

Spoonful of saccharin

Sensory Processes: The New Psychophysics. By Lawrence E. Marks. Pp. x+334. (Academic: New York and London, February 1974.) \$17.50; £8.25.

PEOPLE who use saccharin to sweeten their tea may have noticed a surprising thing: halving the concentration of sugar in a solution reduces its sweetness far more than halving an equally sweet (although much weaker) concentration of saccharin. This is one of many examples that demonstrate differing relationships between sensory magnitude and physical stimulus. How does one measure sweetness, brightness, pitch, odour? It has been shown, particularly in the pioneering work of the late S. S. Stevens, that asking subjects to assign numbers to sensation strength leads to a power function with an exponent dependent upon the stimulus and sensation considered. Lawrence Marks draws a clear distinction between this, the "new" psychophysics, and sensory physics, the "old" psychophysics, in which the observer is simply a detector of threshold, masked threshold, or null point, with measured quantities all in the physical domain. He describes and attempts to interrelate the various psychophysical procedures such as fractionation, category rating, and magnitude estimation and discusses the influences of extraneous factors. The senses are each considered under the headings of sensitivity, temporal and spatial factors, and qualitative aspects. Although one detects a certain antipathy towards the "old" psychophysics it is a carefully reasoned and comprehensive account and shows great concern for validation of the approach. Unfortunately his rather detached attitude coupled with the large number of references makes difficult reading in parts and a certain amount of repetition is inherent in the organisation he has adopted.

Although the new psychophysics gives insights into sensory processes not obtainable in any other way the field has a certain contrived air to it. We do not generally use our senses, or numbers, in this way. We normally use our sensory systems to perceive objects and relationships in the outside world. The idea that perceptions are built up from elementary sensations has been superseded by the concept of perception as an active, generative, process. We frequently see more than our sense organs convey because of past experience and expectations which can be triggered by a few salient features of sensory data. In this wider, more complex field of perception, detection could be of greater importance than sensory magnitude.

J. P. WILSON

Bouncing molecules

Chemical Applications of Molecular Beam Scattering. By M. A. Fluendy and K. P. Lawley. Pp. xi+400. (Studies in Chemical Physics.) (Chapman and Hall: London; distributed in the USA by Halsted Press, 1973.) £8.

THIS book is to be welcomed as the first non-specialist account of a challenging new field of chemical physics: the direct investigation of binary collision processes by the molecular beam technique. The authors discuss the design, performance and interpretation of the experiments, and also give an outline discussion of the background theory. The coverage reflects the present development of the field with major emphasis on elastic scattering and reactive processes.

The strongest chapters are those which deal with the technical design of the apparatus and with the analysis of elastic scattering experiments. Of these the sections of molecular beam sources, energy and state selection and detection and measurement will be of interest to a wide range of experimentalists. Readers with a more theoretical bias will be attracted by the clear account of quantal interference phenomena, seen not as abstract effects, but as sources of additional information in establishing the relation between the elastic scattering cross-sections and the intermolecular force field. The discussion of reactive scattering is equally complete in relation to present understanding, but the intrusion of mathematical detail makes it less easy to follow a clearly defined line of argument. Nevertheless there are few such comprehensive introductions in the literature. I only wish that the bibliography, which covers the important experimental work published before May 1972, could have been extended to include more recent studies on non-alkali atom systems, and that the tables could have contained a fuller resumé of available experimental information.

The level is that of the graduate student, since few undergraduates will have the necessary mathematical background. As such the book will be a welcome addition to the shelves of every serious chemical physics library.

M. S. CHILD

A cool look at doom

Man's Responsibility for Nature: Ecological Problems and Western Traditions. By John Passmore. Pp. x+213. (Duckworth: London, April 1974.) £5.95 cloth; £1.95 paper.

THE so-called 'environmental crisis' has been treated by scientists, economists and theologians, at levels ranging from

clinical objectivity to crude polemics; and it has been exploited by journalists and television producers. It is now the turn of philosophers; Professor Passmore's book is doubtless the first of a shelf-load of philosophical reflections on doom. It sets a very high standard in erudition, accuracy and clarity. The book opens with a masterly summary of the history of man's attitude to nature. Passmore is slightly apologetic about including this; he assures any anti-historical readers that they can, if they wish, skip it and go straight on to the second part of the book, dealing with ecological problems. In fact the historical essay is the best part of the book, and the only part with anything new to say. It describes vividly the Judaeo-Christian attitude to man, which divides him from other living things and makes him unique by investing him with a soul. This anthropocentric tradition has been blamed for man's exploitation of nature and it has prompted some writers to suggest that Western societies will not show proper concern for the environment unless they adopt a new ethic or a new religion, perhaps borrowed from the East.

Passmore argues powerfully and persuasively against this attitude, and especially against the implication that a scientific and rational attitude to nature cannot be reconciled with concern for the environment. The business of science, he says, is to turn mysteries into problems; only then can one set about trying to solve them. It was Descartes and Bacon, not the author of *Genesis*, who propagated the view that man can do as he pleases to nature with impunity. But there is no guidance to be found in the views of some contemporary theologians either; Passmore rejects Bishop Montefiore's idea of stewardship and Teilhard de Chardin's idea of cooperation with nature. He has no use for the arcadian musings of *Blueprint for Survival*. He realises that intellectuals like himself would be the first people to suffer if society were to discard some of the conveniences of modern technological society, such as air travel and motor cars.

From his historical summary Passmore turns to the contemporary ecological problems, which he distinguishes from "problems in ecology": the latter are scientific; the former are social. He covers familiar ground, reminding his readers (though it is superfluous for anyone likely to read this book) that ecological problems have three components: scientific, economic and ethical; and he brings the reader to the familiar conclusion: that the solution to ecological problems must be politically feasible. It is at this point that

the reflections of a philosopher might be expected to illuminate the issues. Unfortunately (but not surprisingly) Passmore's lucid analysis, like that of so many other writers, comes to a stop. We know that some ecological problems (such as pollution) can be solved within the framework of Western democratic institutions. We suspect that others (such as the dedication to ever-increasing material consumption) cannot. Before political decisions can be made an ethical question has to be answered: What duty, if any, do we have to posterity? If we cannot make sacrifices to ameliorate the human condition in the third world, which we have seen, is it likely that we shall make sacrifices to ameliorate the human condition of our great-grandchildren, whom most of us will never see?

Passmore seems to have a vague and tentative belief that this ethical question is soluble by rational thought in the framework of Western democratic institutions; perhaps by acting with concern for our offspring and expecting that they will act with equal concern for their offspring. It is a very modest conclusion to a very sophisticated essay. But Passmore is right to be modest. Heroics and utopias are the opiate of environmentalists. We can hope to proceed only through what William Blake called "Minute Particulars".

E. ASHBY

Defects in oxides

Oxide Semiconductors. By Z. M. Jarzebski. Translated from the Polish by B. Grzybowski-Swierkosz. Translation edited by Brian Randall Pamplin. Pp. xi+285. (Pergamon: Oxford and New York; Wydawnictwa Naukowo-Techniczne; Warsaw, January 1974.) £6.

THIS is a translation of a treatise by a member of the Warsaw Research Centre for crystals and its title is misleadingly broad. It is written by an oxide physicist for oxide physicists and concentrates on the transport of carriers in these materials as influenced by defects. It certainly does not attempt to teach, although an early chapter, on preparation techniques for oxides, provides a useful survey of one aspect of oxide technology. The main interest of the author is the effect on the conductivity of oxides produced by heating them at various pressures of oxygen; the last half of the book is a survey of such effects in about ten metal oxides. The data on carrier transport are exhaustively reviewed but the physical mechanisms involved in this transport are referred to in a rather passing manner and certainly not treated at any depth.

The physics of the structure of defects in the oxides is avoided in a

manner which might almost be called studied, as if the author held that it was quite enough to note the entrance and exit of an electron or hole from the oxide without worrying very much about what happened to it while in this medium, except to note an activation energy for the process. This extends even to the chapters on zinc oxide, aluminium oxide and silicon dioxide, for which, in fact, a rich literature on defect structure exists. Other subjects which one would expect to be treated in a book of this title are carrier trapping (no mention at all); band and hopping conduction models (glancing references only); the role of the d orbitals in defect and band structure in the transition metals (orbitals mentioned only occasionally in passing); and the applications of oxide semiconductors (not even a bibliographical reference given). A subject which is treated well in the explanatory chapters is the law of mass action applied to interactions between oxide and oxygen at high temperatures, in which defects are treated as an active participant in the chemical reaction.

There seems somehow to be a gulf between the kind of defect science described here and the world of 'frozen-in' defects typical of radiation damage and mechanical deformation; the latter science uses a wide range of spectroscopic and scattering measurements to build structural and wave-mechanical pictures of defects, while the former relies largely on measurements of the transport of electrons or atoms in the solid. This book, while it can be read without difficulty, perhaps even with profit, by one of the 'frozen-in' community, does not bridge that gulf. Moreover, those who wish to use this book as a quick summary of the field should note that the references do not, except for a few cases, extend past 1970.

A. G. HOLMES-SIEDLE

The chemical industry

The Chemical Economy: A Guide to the Technology and Economics of the Chemical Industry. By B. G. Reuben and M. L. Burstall. Pp. xix+530. (Longman: London, February 1974.) £6.95.

THAT chemistry courses must become more relevant has been the anguished cry of students and a source of frustration for many teachers of that subject for the past decade. Drs Burstall and Reuben have demonstrated what sort of effort is required if a beginning is to be made. They have written a long book crammed full of information directly related to their title. The book is well organised and the data in it are clearly presented so that prospective

readers are guided step by step through the complexities of chemical technology without undue fatigue. The primary objective of the book is to answer the question "How do we put chemistry to work for us?". As a second objective they intend to do something, in the concrete, to improve the spirit of university-industry cooperation. By providing such a lively and contemporary account of the ways in which chemical technology is used by the industry, the authors have achieved both of them. The book is aimed at an audience of first year university students having an A-level qualification in chemistry but no previous training in economics is presupposed.

This work is not an introductory course in chemistry juxtaposed with an elementary introduction to economics. Quite the contrary. The greater part of the book discusses a wide range of chemical reactions and processes but sight is never lost of the socioeconomic setting in which they function. By describing petroleum, natural gas, heavy organic chemicals, polymers, soaps and detergents, dyes and pigments, pharmaceuticals and heavy chemicals in relation to the firms, predominantly those in the United Kingdom, which utilise them, one is led, albeit in a piecemeal manner, to build up a picture of the chemical industry. A further section attempts to set the UK chemical industry into the world-wide complex of chemical industries. A disappointing feature of the presentation—though it would be difficult to remedy—concerns the historical description of the factors that have led up to the application of a particular process. These descriptions tend to be rather too brief and, consequently, may give the impression that chemical technology develops largely from discoveries in chemistry which appear, somewhat fortuitously, a little while before they are actually needed. None the less for students, who presumably know very little about this sector of industrial activity, it is perhaps a reasonable compromise to ensure that at least a little history is included with the technical and economic factors in the description of the industry.

The book also explores, in a descriptive manner, the economics of the firm. The aspects of microeconomics which are discussed include the decision of management to invest money in a new process and a very interesting section entitled "How do you know you are making money?". In a further chapter the authors discuss some of the problems of scaling up a laboratory experiment to industrial production. This leads to a discussion of the problems of disposing of the wastes from these processes and thence to some of the problems associated with pollution by in-

dustrial effluents.

The authors have produced a book which is doubly useful. It will certainly be useful for students of the growing number of broad-based science courses who are demanding that their curricula be relevant both to the society they live in and the sorts of jobs they may expect. For them it will provide more than a set of introductory materials because the authors have so organised the book that by following up the many references and footnotes, the student will be able to approach more closely the core of many contemporary technical and social problems. Also for the academic who is being asked to prepare more socially relevant course material this book should provide a useful guideline.

MICHAEL GIBBONS

Computer techniques

Operating Systems. By D. C. Tsichritzis and Philip A. Bernstein. Pp. xviii+298. (Computer Science and Applied Mathematics: a Series of Monographs and Textbooks.) (Academic: New York and London, March 1974.) \$13.50; £6.36.

OPERATING systems research seems to have become a popular line with computer scientists, perhaps from a desire to put their own house in order before dealing with more general techniques. Most books about it fall into a middle range, assuming basic knowledge and providing abstracts of the more subtle techniques described in journals.

The authors of this book are clearly competent in their subject, so it is unfortunate that the book is not more readable. The volume is best described as loosely written, and the authors themselves felt compelled to apologise (page 121) for the incoherence of the first five chapters. In particular, the frequent cross references embedded in the text are particularly difficult to follow. Footnotes would have been much easier to scan, and would have helped maintain a continuity within the main text. The entire work carries an air of editorial neglect, and falls into the trap of collaborative work, repetition. Although the book starts at a low level, it would be very difficult for a student to follow.

Apart from the problems at the end of each chapter, and the admirable bibliography, the most worthwhile chapters cover design and implementation principles, dealing with problems of project management plus a collection of the authors' solutions. The book could be worth buying for these chapters alone; in fact the width of scope leaves me wondering why they did not publish three well organised volumes, instead of trying to cram the entire subject into 300 pages.

JEFFREY GRIBBIN

"It's like this . . ."

An exhibition of 500 years of pictures for science at Nottingham Castle, until September 15th.

Not so much an exhibition of pictures 'for science' as an exhibition of illustrations designed to make apparent that which is not immediately so, and with a rather heavy emphasis on anatomy and mechanics at the expense of 'pure' science notions. The devices which illustrators have employed in order to reveal the unseen realities of man's world, range from the simple stripping of skin from muscle and skeleton, to the cross-sectional representation beloved of Victorian steam engineers, on to the scanning electron microscope, whose shaded and textured images have so captured the lay reader's curiosity as to merit page spreads in the Sunday supplements on purely aesthetic grounds. Alas, no 200,000 times magnified study of the human sweat gland in sight here, but the bristle of a caterpillar does service to amaze the casual visitor.

The aim of the exhibition is not so much to illustrate the history of science as to make familiar some of the more visually striking works done for it. According to the organisers the visual interest of the pictures is firstly in the information which they were made to convey, but in the best of them this is raised to a 'celebration of understanding'—a rather attenuated concept to keep in mind when browsing over Robinson's engine working gear or Davis's Fire Escape Machine, regardless of the sturdy commonsense that these undertakings embodied. The impression one gathers from the narrative explaining the Fire Escape Machine is rather one of a mind awakening from slumber, and peering unsteadily at the ordering of things, than of a *bona fide* celebration of understanding.

"On the alarm of fire," John Davis remarked, circa 1810, "I would have the machine brought out directly, as I consider it an improvident method when a house has been on fire some time to have to search about for the keys of the church yard or some other obscure place, to bring the fire ladders . . ."

The celebratory aspect of the science illustrator's work is most plainly evident in the anatomical woodcuts and engravings of the centuries preceding the invention of photography. From the mediaeval autopsy studies of Mondino de' Luzzi, who dissected corpses in cases of suspected foul play, to Joseph Maclise's plates from the Victorian *Surgical Anatomy*, there is a distinct sense that apart from providing maps and tools for surgeons, the artists were revelling in the insights which their probing of cadavers had revealed. The

unravelling arrangement by Govaert Bidloo and Gerard de Lairese of the ligaments whose contractions control the movement of the human hand, for example, is presented with an objectivity which might equally have been applied to a study of a marionette's limb. And thereby the point is made: that the workings of human machinery are as much a function of mechanical and chemical laws as that of everything else in the universe—not an entirely uncontroversial proposition half way through the seventeenth century.

Apart from the insights which raise many of these studies to the level of fine art, one is aware of a scrupulous technical achievement in their execution and their conventions. The study on this week's cover, by Albinus and Wandelaar, is one of six plates derived from the *Tabulae Skeleti et Musculorum Corporis Humani* of 1747, a brilliantly engraved series, employing devastatingly complex perspective techniques devised by a professor of physics to ensure accuracy and uniformity. Albinus' own account of the process offers an understanding of the niceties involved:

"Not a single figure" wrote Albinus, "has been drawn free hand. All have been measured and brought down to scale, either from an indeterminate distance, as the architects do, a method which has been followed in most cases, or from a distance of 40 feet through diopeters which correct to an indeterminate distance in such cases as, for instance, the pictures of skeletons, upon which finally, as upon a ground plan, the muscles have been drawn in. The tiny bones of the ear the artist measured with a very small and perfect compass." A system of nets in front of the subject allowed the artist to relate details to the whole in scale when he approached from his 40 feet vantage point to draw details. Most important of all, he drew nothing "he had not first thoroughly understood".

The portion dealing with modern science pictures, called 'Images of the Invisible', loses a little through familiarity: everybody knows from Arthur Mee's encyclopaedia what the drop of milk looks like when splashing into a saucer, and the bullet when hitting the shutter trip-wire. And to a lesser extent the zebra striped schlieren photographs of pressure waves caused by a body moving in a density stratified fluid, and field ion micrographs have lost their power to surprise anybody but the most unobservant man on the Clapham omnibus. The best loved exhibits in the show are camera obscuras which afford views of the city, a reflex camera obscura, which affords one the opportunity of drawing one's travelling companion, and a machine which affords sound the change to be seen by using its varying frequencies to agitate the

surface of a pool of oil. All in all, a worthwhile undertaking which succeeds on its own modest terms.

JOHN HALL

Verdict on DDT

DDT has been accused of killing birds and fish, causing cancer, poisoning babies at the breast and disrupting the ecosystem of the oceans. Tuesday's Documentary, "The Rise and Fall of DDT," found the insecticide guilty on the first charge but innocent of all others except the last where a verdict of 'not proven' was reached. In mitigation it was shown beyond all reasonable doubt that DDT has saved the lives of millions of people throughout the world who would otherwise have died from malaria, typhus and other insect-borne diseases. With commendable objectivity the programme did not recommend a sentence.

The case of dichlorodiphenyltrichloroethane (DDT) is certainly a curious one and the producers of the documentary exploited this to their advantage. Although it is now a symbol of all things wrong with intensive farming, DDT was shown to begin life as a revolutionary breakthrough in pest control.

Old newsreel film skillfully illustrated DDT's first really big success in the Second World War. Shortly after the liberation of Naples, it was used there to forestall an epidemic of typhus—the first time that this had been done on a large scale. DDT was also shown to have played a vital part in the campaign against the Japanese. But the recipe for DDT is very simple and soon after the war it was being produced in bulk by various companies. This led to indiscriminate use; indeed DDT became so popular that it was made into an American cocktail—a 'Micky Slim'.

The documentary traced the beginnings of DDT's downfall to 1949 and the use of a similar compound, DDD, against mosquitos in Clear Lake, California. By 1954 the population of a rare grebe on the lake had dropped alarmingly and DDD was blamed. Studies on DDT in other environments followed and lawsuits naming the chemical began to be won. The change in public opinion was so great that even when President Nixon's environmental Protection Agency exonerated DDT, its findings were overruled and the insecticide banned from the United States.

Following this largely historical introduction, Tuesday's Documentary brought forward a long series of scientific witnesses to testify to the damage, or otherwise, that DDT inflicts on the environment. Throughout this argument, the programme success-

fully maintained its impartial attitude, described by one of its producers as "beleagured neutrality".

It is just as well it did for a good deal of the evidence is contradictory. DDT was said to circulate in the air and soil, ultimately contaminating the sea but Dr George Harvey of Woods Hole Oceanographic Institute, Massachusetts, described his failure to find it there. When DDT was seen to distend the livers of mice it was said to lower their tolerance to some chemicals like carbon tetrachloride but actually increase their resistance to others such as aflatoxin. Almost all the evidence in the programme pointed to the sublethal effect of DDT but there was little opposition to the charges that

it was responsible for deaths due to eggshell thinness in birds and increased mortality in fish eggs.

Out of 23 factories which once produced DDT in the United States only one, Montrose Chemicals, survives. Its workers are continuously exposed to a high level of DDT and if there is any truth in the charge that DDT is carcinogenic then it should be found here. But the programme showed that these workers actually have a lower incidence of cancer than normal. On the dangers to human beings perhaps the most pertinent comment came from Professor James Busvine of the London School of Hygiene and Tropical Medicine who felt that DDT has never been proved to cause the death of a single

person but has undoubtedly saved up to ten million lives.

Just before the end of the film the increasing resistance of many insects to DDT was briefly mentioned. Nature itself seems to be passing the final judgment on DDT as more and more pests become immune to its effects. As the future of many underdeveloped countries depends on effective pest control and the use of DDT and other insecticides is becoming increasingly unsatisfactory (even leading to an increase of the pest in some cases), insect resistance is surely important enough to warrant more than this cursory treatment in an otherwise informative and balanced production.

M. A. Sleight has been appointed to the chair of biology at the **University of Bristol**.

International meetings

September 19–20, **551st Meeting of the Biochemical Society**, University of St Andrews (The Meetings Officer, The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP).

September 24, **The Use of Molten Salts in Surface Treatment**, Leatherhead (Dr A. J. B. Cutler, C.E.R.L., Kelvin Avenue, Leatherhead, Surrey, UK).

September 24–25, **552nd Meeting of the Biochemical Society**, University College, Galway (The Meetings Officer, The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP).

September 25–26, **Symposium on the Chemistry of Liquid Metals**, University of Leicester (Dr John F. Gibson, The Chemical Society, Burlington House, London W1V 0BN).

October 3, **Symposium on Micro Organisms in Food**, University of Leeds (Mr A. J. Crowther, The Metal Box Co. Ltd., 24 Fennel Street, Manchester M4 3FH, UK).

October 6–9, **6th Lunteren Lectures on Molecular Genetics**, Netherlands (Dr W. P. M. Hoekstra, Department of Microbiology, State University of Utrecht, Padualaan 8, Utrecht, The Netherlands).

October 7–12, **22nd International Meeting of Transportations and Communications**, Genoa (Segretaria Generale I.I.C., Villa Piaggio, Via Pertinace, 16125 Genova, Italy).

October 10–12, **Genetic Engineering: Danger or Hope**, Davos (Rudolf Brun, Gottlieb Duttweiler Institute for Economic and Social Studies, CH-8803 Rüschlikon, Switzerland).

October 24, **Inaugural Meeting of the Hydrogeological Group of the Geological Society of London**, London (Dr J. D. Mather, Geological Society of London, Burlington House, London W1V 0JU).

Errata

In the article "Memory in enzyme membranes" by A. Naparstek *et al.* (*Nature*, **249**, 490; 1974) the legend to Fig. 1 should read . . . internal pH as a function of decreasing (a) and increasing (b), the external pH values.

In the article "Bioassay of a *Drosophila* pheromone influencing sexual selection" by J. E. Leonard, L. Ehrman and M. Schorsch (*Nature*, **250**, 261; 1974) the blocks for Figs 1 and 2 were reversed.

APPOINTMENTS VACANT**UNIVERSITY COLLEGE GALWAY
JUNIOR LECTURESHIP IN BOTANY**

Applications are invited for the above post. Salary scale £2,478 by 99 (10) to £3,468 p.a. plus Family Allowances. Applications will be particularly welcome from candidates with a specialised knowledge of Irish vegetational history.

The closing date for receipt of applications is **September 12, 1974**. Prior to application, further information should be obtained from the Registrar of the College. (738)

**The Marie Curie
Memorial Foundation
THE CHART, OXTEAD RH8 0TL**

1. **RESEARCH ASSISTANT FOR THE METABOLIC UNIT** with a degree in Nutrition or Biochemistry and an interest in clinical research in cancer. Experience of drug metabolism would be an advantage.
2. **RESEARCH ASSISTANT FOR THE BIOLOGICAL CHEMISTRY UNIT** with Grad. R.I.C., or B.Sc. (Hons) in chemistry, with an interest in organic chemistry. Current projects involve the design, synthesis and evaluation of new anti-tumour agents and metabolism of anti-cancer drugs.
3. **RESEARCH ASSISTANT FOR THE IMMUNOCHEMISTRY UNIT** with a degree in biochemistry to investigate the role of acid hydrolases in tumour invasion and metastatic spread. Experience in immunochemical and biochemical analytical techniques would be an advantage.

Salaries are based on the Whitley Council Scale with superannuation. Successful applicants may register for a higher degree after an initial probationary period. Applications including the names of two referees and indicating the post sought should be sent to the Secretary at the above address. (802)

**UNIVERSITY OF GLASGOW
DENTAL HOSPITAL AND SCHOOL
RESEARCH ASSISTANTSHIP IN
DENTAL BIOCHEMISTRY**

Applications are invited for a **RESEARCH ASSISTANTSHIP IN DENTAL BIOCHEMISTRY**, tenable for a period of up to four years from October 1974.

Candidates should have an Honours Degree in Biochemistry, Microbiology or an allied subject. There will be an opportunity to apply to register for a higher degree.

The work will be mainly concerned with the synthesis of glucans by extracellular bacterial enzymes.

Salary scale £1,500 by £75 to £1,725. F.S.S.U. Applications, including curriculum vitae and names of two referees, should be sent to Dr J. A. Beceley, University of Glasgow Dental School, 378 Sauchiehall Street, Glasgow G2 3JZ, from whom further information may be obtained.
In reply please quote Ref. No. 3527M. (792)

THE UNIVERSITY OF ASTON IN BIRMINGHAM**Department of Pharmacy****RESEARCH IN MEDICINAL AND
PHARMACEUTICAL CHEMISTRY**

As part of the Department's expanding research activities, the following posts are available:

RESEARCH FELLOW IN HETEROCYCLIC CHEMISTRY
(Ref. 984/6)

The candidate will be expected to investigate the chemical and/or biological properties of novel Nitrogen Heterocyclic Systems of potential biological importance, and to undertake a limited amount of teaching at M.Sc. level in an area of Medicinal Chemistry.

The Fellowship is tenable for up to 2 years 9 months. The commencing salary will be within the range £2,118 to £2,412 per annum with effect from October 1, 1974. The post is superannuable.

RESEARCH ASSISTANT IN TOXICOLOGICAL ANALYSIS
(Ref. 985/6)

The successful candidate will work on problems concerned with the assessment of levels of environmental pollutants in placental tissues, and will join an interdisciplinary group from the University and the Departments of Human Genetics and Pathology at Birmingham Maternity Hospital. Preference will be given to candidates having some experience of atomic absorption spectrometry, polarography, gas chromatography, neutron activation analysis, or other appropriate instrumental technique.

The post is tenable for up to 3 years and the starting salary will, with effect from October 1, 1974, be within the range £1,395 to £1,659 per annum on a scale rising to £2,058 per annum.

Requests for further details of these two posts and application forms (which should be returned not later than September 6) should be sent, preferably on a postcard, quoting the reference number, to the Staff Officer, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET.

RESEARCH STUDENTSHIPS

Applications are invited from suitably qualified graduates to undertake research in the following areas:

Heterocyclic medicinal chemistry

Characterisation of biologically active compounds in coal-tar fractions

X-ray crystallographic and other instrumental methods for the analysis of biologically active materials

Grants are based on S.R.C. regulations and may be augmented by demonstrating duties. Candidates would be expected to register for Higher Degrees of the University.

Further details of these studentships may be obtained from Dr M. F. G. Stevens, Department of Pharmacy, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. Returnable by September 6, 1974.

(844)

**CENTRAL PUBLIC HEALTH
LABORATORY**

Honours Science Graduate required by the Standards Laboratory for Serological reagents for work with viral diagnostic reagents.

Applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London, NW9 5HT. (749)

**THE GRASSLAND RESEARCH
INSTITUTE**

HURLEY, MAIDENHEAD, BERKSHIRE

A vacancy exists for a **SENIOR SCIENTIFIC OFFICER/PRINCIPAL SCIENTIFIC OFFICER** to study the principles underlying the utilisation of grass by grazing cattle, with emphasis on sward and animal factors influencing the productivity of dairy cows.

Minimum qualifications: 1st or 2nd class honours degree in an appropriate subject and relevant post-graduate experience.

Salary: Senior Scientific Officer £3,157 to £4,441 p.a.; Principal Scientific Officer £4,227 to £5,550 p.a. There is a non-contributory superannuation scheme.

Applications to the Secretary by September 14, 1974 with curriculum vitae and the names of three referees and quoting 6/C/8. (823)

**THE UNIVERSITY OF SHEFFIELD
W. E. S. TURNER CHAIR OF
GLASS TECHNOLOGY**

Applications are invited for the **W. E. S. TURNER CHAIR OF GLASS TECHNOLOGY** which will become vacant in September 1975 on the retirement of Professor R. W. Douglas. Salary in the range approved for professorial appointments with superannuation provision. Further particulars may be obtained from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications (one copy only) should be sent by September 21, 1974. Please quote reference R116/G. (808)

(RE-ADVERTISEMENT)**THE UNIVERSITY OF MANCHESTER
LECTURER IN ZOOLOGY**

Applications invited for this post, for which an interest in neurobiology would be an advantage. Salary scale p.a.: £2,118 to £4,896. F.S.S.U. Initial salary not above £2,580 p.a. Particulars and application forms (returnable by September 20) from the Registrar, The University, Manchester M13 9PL. Quote ref: 186/74/N. (813)

BOC

PHD POLYMER CHEMIST

Research Project

BOC are sponsoring a research project in polymer chemistry at the University of Aberdeen Department of Chemistry, Physical Chemistry Section to commence Autumn 1974. The project is concerned with the separation of gases by permeation through polymer membranes and hollow fibres.

BOC will employ the person appointed, initially on a 2-year secondment as Honorary Fellow to the University. Upon completion of this period career development alternatives might include continuation of this project in the employ of either BOC or the University, or other scientific posts within BOC or the University.

Candidates, aged between 24 and 28, should have recently gained (or be about to gain) a doctorate in Organic or Physical Chemistry, and be particularly interested in undertaking applied research for industry. Salary negotiable; first class pension scheme and terms of employment; removal expenses if appropriate.

Please apply to:

Dr D. W. Kirkley,
New Venture Secretariat,
British Oxygen Company Limited,
Hammersmith House,
London W6 9DX.

(812)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

Applications are invited from suitably qualified persons for the following posts:-

- LABORATORY TECHNICIAN—BIOCHEMISTRY**
Grade 4. £1,848 to £2,163 per annum.
To assist research involving chemical synthesis and evaluation of novel compounds and to assist with undergraduate practical classes. Ref: 274/T/NA.
- LABORATORY TECHNICIAN—BIOCHEMISTRY/MICROBIOLOGY**
Grade 4. £1,848 to £2,163 per annum.
To be responsible for technical support to medical and science undergraduate Biochemistry/Microbiology classes and provide some support for related research. Ref: 275/T/NA.
- LABORATORY TECHNICIAN—PHARMACOLOGY**
Grade 3. £1,650 to £1,920 or Grade 4. £1,848 to £2,163 per annum, according to qualifications and experience.
To provide technical support for Science undergraduate Pharmacology/Mammalian Physiology classes and research. Ref: 276/T/NA.
- PHOTOGRAPHIC/REPROGRAPHIC TECHNICIAN**
Grade 3. £1,650 to £1,920 or Grade 4. £1,848 to £2,163 per annum.
To provide a departmental photographic service, to produce slides, and to prepare diagrams, graphs and illustrations. Ref: 277/T/NA.
- LABORATORY TECHNICIAN—RADIOISOTOPIC SERVICES**
Grade 3. £1,650 to £1,920 per annum.
To be primarily responsible for radioisotopic facilities in the Analytical Services Unit. Experience of instrumentation and/or chemistry/biochemistry. Ref: 279/T/NA.
- ELECTRON MICROSCOPY TECHNICIAN**
Grade 2B. £1,524 to £1,794 per annum.
To join a unit providing Electron microscopy services. Some experience of E.M. work and/or histology. Ref: 281/T/NA.

Cost of living allowance currently £2.40 per week payable in addition to salary shown.

Posts 1-4: Related experience, an appropriate qualification (minimum O.N.C. or equivalent) and enthusiasm are required for these established appointments. Graduates in appropriate disciplines are welcome to apply for posts 1-3.

Posts 5-6: Minimum qualification for these posts O.N.C. or equivalent in appropriate subjects.

Applications giving details of age, qualifications and experience and the names of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting appropriate reference number. (730)

"METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS. The work consists of editing, indexing, and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, 1 Carlton House Terrace, London SW1Y 5DB. (829)

HOUGHTON POULTRY RESEARCH STATION

HOUGHTON, HUNTINGDON, CAMBS.

ELECTRON MICROSCOPIST LEUKOSIS EXPERIMENTAL UNIT

Applications are invited from veterinary graduates with experience in electron microscopy, and preferably with a higher degree, for a research post with a group studying avian tumours and their causative viruses, with particular emphasis on Marek's disease, to obtain an understanding of pathology at the ultrastructural level and its relation to Marek's disease and other diseases of poultry. The successful candidate would be in charge of a small electron microscope unit. Some collaborative work with other departments would be required.

The appointment will be made in the V.R.O. (£2,616 by 7 to £3,312) or S.V.R.O. (£3,312 by 7 to £4,004) grades, salaries (currently under review) depending upon qualifications and experience. There is a non-contributory superannuation scheme.

Further particulars and application form from the Secretary to whom completed application form should be returned by September 20, 1974. (822)

UNIVERSITY OF SUSSEX SCHOOL OF BIOLOGICAL SCIENCES

Postdoctoral Research Assistants

required for project on:-

- The biochemical basis of plasma membrane modifications associated with cell transformation.** Experience with membrane enzymes, enzyme isolation and purification of glycolipid biochemistry would be an advantage. The project is supported by the Cancer Research Campaign, it is for one year in the first instance and is renewable. Salary will be on University Lecturer scale up to £3,400 a year according to experience and qualifications.
- The changes in the biochemistry of the cell nucleus induced by chemical carcinogens.** Experience with enzymes or with chromatin would be an advantage. The project is supported by the Cancer Research Campaign, it is for one year in the first instance and is renewable. Salary will be on University Lecturer scale up to £3,000 a year, according to experience and qualifications.

Applications for both posts with the names of three referees to Dr S. Shall, School of Biological Sciences, University of Sussex, Brighton BN1 9QG. (805)

QUEEN MARY COLLEGE
University of London
CHEMISTRY DEPARTMENT

Applications are invited for an S.R.C. supported Postdoctoral Research Assistant, tenable for 1 year from October 1, for work in collaboration with Drs F. A. Hart and G. P. Moss on Fundamental aspects of lanthanide n.m.r. shift reagents. Experience in preparative coordination chemistry and/or organic chemistry in addition to n.m.r. spectroscopic experience required. Salary within range £2,118 to £2,247 p.a. plus £213 London Allowance. Applications in writing (giving qualifications, previous scientific experience and names and addresses of two referees) to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS. (821)

UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES

Applications are invited for the post of DEMONSTRATOR. This post is tenable for up to three years. Candidates are expected to give assistance in the preparation and demonstrating of undergraduate practicals, and in tutorial work, and to carry out research in aspects of soil science related to a major departmental research programme on minimum cultivation methods.

Candidates should have a good Honours Degree, and preferably some research experience, with training or experience in soil science (physics or soil chemistry).

The salary is in the range of £1,290 to £1,971 (under review). Successful applicants may work for a higher degree during their tenure of the post. Application forms and further particulars from the Registrar, University of Leeds Leeds LS2 9JT (please quote reference 41/26/D). Closing date August 31, 1974. (806)

UNIVERSITY OF EXETER
DEPARTMENT OF BIOLOGICAL SCIENCES
POSTDOCTORAL RESEARCH
ASSISTANT

Applications are invited for a Postdoctoral Research Assistant to work with Dr H. Stebbings on "Cytoplasmic microtubules and their rôle in cellular and intracellular movements". The research will involve ultrastructural, biochemical and physiological studies on a number of microtubule systems, and preference will be given to applicants who have been working in this field. Previous experience of electron microscopy is essential.

The appointment is for two years from either October 1, 1974 or such date thereafter as may be mutually agreed, with an initial salary of £2,118 p.a. plus F.S.S.U.

Applications, together with a curriculum vitae giving details of age, qualifications and experience, and the names of two referees should be sent by September 13, 1974 to The Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ. Please quote reference 1/12/7081. (817)

university of wales
**university
college of
swansea**

Research Assistant

Applications are invited for the vacancy of Research Assistant in the Department of Botany and Microbiology. Applicants should have a degree in a biological subject, preferably in genetics and the successful applicant will work with Professor P. J. Syrett on genetical aspects of the control of nitrate assimilation in *Chlamydomonas*.

The appointment, which will be for one year in the first instance, will be £1,410 per annum.

Further particulars and application forms may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP to whom they should be returned by **Monday, September 9, 1974.** (814)

**NORTHAMPTONSHIRE
AREA HEALTH AUTHORITY**

Northampton General Hospital

Applications are invited for the post of

**Basic Grade
Biochemist**

(post probationary) in busy and well-equipped Clinical Chemistry Department. Previous experience in immuno-logy and radioimmunoassay desirable but not essential.

Applications with details of age, qualifications and experience, together with names and addresses of two referees to Dr G. P. Fraser (telephone Northampton 34700 Ext. 514) from whom further particulars may be obtained.

(810)

**DEPARTMENT OF
AGRICULTURE**

Applications are invited for a permanent and pensionable post in the Crop and Animal Husbandry Division.

The successful applicant will undertake work on pig production with special reference to increased efficiency and may be required to undertake teaching duties in the Faculty of Agriculture, The Queen's University, Belfast.

The appointment may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level.

S.S.O. Over 25 and under 32 years of age with a 1st or 2nd Class Honours Degree in Agriculture and at least 4 years post-graduate experience preferably in relation to pig production.

H.S.O. Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

S.O. Under 27 years of age with an Honours Degree as above.

Salary Scales: S.S.O. £3,157 to £4,441; H.S.O. £2,461 to £3,371; S.O. £1,592 to £2,675.

Grading and salary will be related to qualifications and experience and a cost of living supplement is also payable.

Please write or telephone for an application form and further information, quoting Ref. SB 227/74/N to Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26).

Completed forms must be returned to arrive not later than September 17, 1974.

**NORTHERN IRELAND
CIVIL SERVICE**

(828)

**The Lister Institute of Preventive Medicine
(University of London) Elstree, Herts**

requires a

BACTERIOLOGIST

to undertake investigative and developmental work on bacterial vaccines and therapeutic sera. This post is one of responsibility and offers plenty of scope for interesting and rewarding research; it is suitable for a worker with a doctoral degree or of comparable seniority. Salary in accordance with experience and qualifications. Superannuation under F.S.S.U.

Applications to:

**Secretary, Lister Institute of Preventive Medicine,
Elstree, Hertfordshire.**

(859)

**UNIVERSITY OF SINGAPORE
PHARMACOLOGY**

Applications are invited for teaching appointments in the Department of Pharmacology. Candidates should have an interest in teaching and research in Medical Pharmacology. Gross monthly emoluments in the range from S\$1,310 to S\$ 4,190 approx., the initial amount depending on the candidates's qualifications and experience and the level of appointment offered. The gross emoluments comprise basic salary and the National Wages Council wage allowances. In addition, the University pays a 13th month annual allowance of one month's basic salary in December of each year; and contributes to the staff member's provident fund at 15% of basic salary and allowances. Leave, medical, housing and other benefits are also available. Candidates should write to: The Registrar, University of Singapore, Singapore, giving curriculum vitae (bio-data), with full personal particulars, and also the names and addresses of three referees.

Exchange rate, approx. Stg. £1 = S\$5.85.

(835)

**UNIVERSITY OF BRISTOL
DEPARTMENT OF PATHOLOGY**

A vacancy exists for a RESEARCH TECHNICIAN GRADE 5, having H.N.C. or equivalent qualifications plus several years relevant experience, to take charge of an electron microscope unit within the Department. Experience in cell biology is desirable. The work will involve also the use of sophisticated electronic and optical equipment in connection with studies on brain damage, investigations on tissue culture and a general supervisory responsibility for the running of a small laboratory.

This 'funded' post, which is tenable from November 1, 1974 at the School of Veterinary Science, Langford, carries a salary related to U.T.S.S. scale Grade 5, £2,007 by £75 to £2,382 per annum. The present grant, which is renewable, runs to December 1977 initially.

Applications in writing, giving the names and addresses of two referees, to Professor I. A. Silver, Department of Pathology, Medical School, University Walk, Bristol BS8 1TD. (820)

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
DEPARTMENT OF BIOCHEMISTRY
AND CHEMISTRY**

Applications are invited for the post of RESEARCH TECHNICIAN to work on biological membranes and cell fusion in a project supported by the Medical Research Council. The post is for one year in the first instance, renewable to July 31, 1976. Initial salary, depending on age and experience, from £1,692 per annum plus £126 London Weighting allowance and Threshold Payments.

Please apply as soon as possible, giving a curriculum vitae and the names of two referees, to Professor J. A. Lucy, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (816)

**UNIVERSITY OF EXETER
DEMONSTRATORSHIP IN
PHYSICAL CHEMISTRY**

Applications are invited for a Demonstratorship in Physical Chemistry, tenable from October 1, 1974 for two years. Applicants should have a Ph.D. degree or equivalent research experience.

Salary within the range £1,941 to £2,247 per annum with initial placement in accordance with qualifications and experience. The post is superannuable.

Further particulars may be obtained from: The Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ, to whom applications (six copies; overseas applicants one copy), together with the names of two referees, should be sent by September 15, 1974. Please quote Reference No. 1/12/3093 in all correspondence. (815)

BBC RADIO SCIENCE PRODUCER

to produce "Science Now", "Scientifically Speaking" and similar programmes.

Thorough knowledge of developments in science, scientific curiosity and editorial judgement essential. Science degree and journalistic experience desirable. Based Broadcasting House.

Salary £2,967 p.a. (may be higher if qualifications exceptional) rising by annual increments of £135/156 to £4,023 p.a. maximum, plus cost of living threshold payments currently £10.42 p.m. month and £195 p.a. non-day working allowance. Salary revision due October 1, 1974.

Write or telephone now for application form (enclosing addressed foolscap envelope and quoting reference 74.G.451N) to Appointments Department, BBC, London W1A 1AA. Tel. 01-580 4468 Ext. 4619. (824)

**NORFOLK AREA HEALTH
AUTHORITY**

**GRADUATE
AUDIOLOGIST**

Required to provide a service for the conduct of audiological and vestibular investigations for adults and children at the new Regional Audiology Centre which is being established at the Jenny Lind Hospital, and to undertake combined clinics with E.N.T. surgeons. Although based at the Regional Centre, the Audiologist will also visit other hospitals in the East Anglian region to undertake clinics.

Training of Physiological Measurement Technicians in Audiology for the Region will be his or her responsibility; in addition, the Audiologist will undertake or assist in research projects in Audiology and related fields.

Appropriate qualifications would be B.Sc. or equivalent in Biology, Physiology, Engineering or Mathematics; with a higher degree in Audiology.

The appointment will be on the Scientific Officer Grade, with one year's seniority, with promotion thereafter to Senior Scientific Officer. Commencing salary will depend on qualifications and experience; a graduate with a 1st or 2nd class Honours degree would receive a commencing salary of £1,875 p.a., and for a graduate with a 3rd class Honours degree the commencing salary would be £1,593 p.a.

A Job Description and application form is available from the Area Personnel Officer, Norfolk Area Health Authority, 102/104 Prince of Wales Road, Norwich. An informal visit to the Regional Audiology Centre can be arranged prior to interview.

Closing date for receipt of applications is September 11, 1974.

(811)

Immediate vacancy for a fully qualified

TECHNICIAN

for research work on rheumatoid arthritis utilising immunological and tissue-culture techniques. Previous experience preferable but not essential. Apply in writing, stating age and giving details of education, qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. D.M.3. (837)

**THE INSTITUTE
OF ORTHOPAEDICS**
(University of London)

Royal National Orthopaedic Hospital
234 Great Portland Street,
London W1N 6AD

Applications from graduates in either
medicine or science are invited for the
whole time post of

RESEARCH ASSISTANT

in the

Department of Morbid Anatomy

The appointment is for one year in the
first instance, and is renewable annually.
Salary on the appropriate scale for lecturer
(£3,135 to £4,041 Clinical; £2,118 to £3,462
Non-Medical) according to qualifications and
experience. Superannuation under F.S.S.U.

The post will provide opportunity for
research in the general field of bone structure
and bone pathology, under the supervision
of Prof. H. A. Sissons. For a medically-qualified
pathologist it will also provide training and
experience in orthopaedic pathology. Further
information can be obtained from Prof. H. A. Sissons.

Applications, together with the names of
two referees, should reach the Secretary, at
the above address, by September 30 1974.
(798)

CHEMICAL PATHOLOGIST

An opportunity exists for a Chemical Pathologist within
the Human Pharmacology Department at Brockham Park.
The successful applicant will be responsible for a small
group of technical staff conducting the clinical chemistry
and haematology services for this department.

This challenging new position will be of interest to an
applicant with 2/3 years post graduate experience in
Chemical Pathology.

A good starting salary will be offered and reviewed
regularly. Beecham Pharmaceuticals, Research Division is
part of the Beecham Group and is situated in a pleasant
area of Surrey; within easy reach of London.

The successful applicant will qualify for the Groups
generous bonus scheme and non-contributory pension and
life assurance scheme.

If you are interested in this
vacancy please contact the
Site Personnel Officer,
Beecham Pharmaceuticals,
Research Division, Brookham
Park, Betchworth, Surrey RH3 7AJ,
or ring Betchworth 3202 ext. 55
for an application form.

**UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES**

Applications are invited from graduates with
appropriate qualifications in agronomy for the
post of **RESEARCH OFFICER** in the Department
of Plant Sciences, Leeds University. The appointment
is for one year, with possible renewal for a
further two years, and is associated with a major
research project financed by the Agricultural Research
Council on direct drilling and reduced
cultivation. The person appointed will take charge
of field experiments and assist with the co-ordination
of the experimental requirements of a
small research group. Salary £1,929 by £129 to
£2,058 by £165 to £2,223 (at present under revision).
Application forms and further details from the
Registrar, University of Leeds LS2 9JT (please
quote reference number 4125).

Closing date for applications August 31, 1974.
(807)

**ROTHAMSTED EXPERIMENTAL
STATION**

**HARPENDEN, HERTS. AL5 2JQ
ASSISTANT STATISTICIANS**

to analyse and interpret data from agricultural and
other biological experiments using the Station's
computer. Degree, H.N.C. or equivalent qualification
in mathematics or statistics. Some knowledge
of agriculture or biology an advantage.

Appointment in grade of Scientific Officer
(£1,592 to £2,675). Starting salary according to
qualifications and experience. Superannuation with
a contribution of 14% for family benefits.

Apply in writing to the Secretary giving names
and addresses of two referees and quoting reference
236 by September 15, 1974.
(826)

**UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES**

Applications are invited from graduates
with appropriate qualifications for the post
of **RESEARCH OFFICER** in the Department
of Plant Sciences, Leeds University. The appointment
is for one year, with possible renewal for a further two years,
and is associated with a major research
project financed by the Agricultural Research

Registrar, University of Leeds LS2 9JT
(please quote reference number 41/25/D).

Closing date for applications August 31,
1974.
(807)

Opportunity Overseas

Ghana

Agronomist

To work with local research agronomists at the Crops Research
Institute, Kumasi on a range of crops.

Candidates should have a degree in agriculture or allied science
with experience of agronomic research in tropical countries.
Appointment 18 months in first instance. Salary in scale £4,550
to £6,500 p.a. plus a tax-free allowance in scale £760 to £1,765 p.a.

Other benefits include free family passages, paid leave, children's
education allowances and free accommodation and medical
attention. Applicants should normally be citizens of and
permanently resident in the United Kingdom.

For full details and an application form please apply giving
age and brief details of qualifications and experience to:

Appointments Officer

Ministry of Overseas Development

Room E301 Eland House
Stag Place London SE1E 5DH

(868)

Microbiologist

John Wyeth & Bro. Ltd., an associated Company of Wyeth International of Philadelphia, U.S.A. produce a wide range of Pharmaceutical and infant food products at their modern factory at Havant, Hampshire.

A vacancy exists for a recently qualified graduate in Microbiology who will be required to join a small team involved in the Microbiological Quality Control of pharmaceutical nutritional products.

The company offers a non-contributory pension and life assurance scheme. Assistance with relocation expenses will be considered.

Please apply to:

Mr C. E. Henry,
Staff Personnel Manager,
John Wyeth & Brother Limited,
Huntercombe Lane South,
Taplow, Nr. Maidenhead,
Berks.

or Telephone Slough 28311.

(836)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE FOR RESEARCH ON ANIMAL DISEASES DEPARTMENT OF BIOCHEMISTRY

Compton, Newbury, Berkshire

Applications are invited for a postgraduate studentship available for a suitably qualified candidate to study the nature of the scrapie agent using biochemical and virological techniques. The studentship is funded by the Multiple Sclerosis Society and the stipend will be approximately £1,200 per annum for three years. Opportunities exist to register for a higher degree at the University of Reading, with which the Institute is an associated institution. Hostel accommodation is available in a modern building.

A full curriculum vitae and the names of two referees should be submitted to the Secretary as soon as possible, quoting the reference number 159. (827)

AREA LABORATORY KING EDWARD VII HOSPITAL WINDSOR

Senior Technician, Technician and a Junior Technician required for Microbiology Department. Laboratory provides a comprehensive service for approximately 1,000 beds and for out-patient clinics and general practitioners in the Windsor, Ascot and Maidenhead areas. Expansion of services anticipated. Hospital close to public transport termini and has its own swimming pool.

Applications to Senior Pathologist. Enquiries to Senior Chief Technician. Tel: Windsor 61424. (830)

UNIVERSITY OF GLASGOW DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY RESEARCH ASSISTANT

Applications are invited from Biologists/Biochemists for the post of Research Assistant in the above Department. The post is grant-aided, tenable for a period of three years from October 1, 1974. The project is to study steroid production by human ovarian cells.

Applications will be considered from either Honours Graduates or Postdoctoral Scientists. Salary will be within the range £1,600 to £2,412 per annum according to age, qualifications and experience.

Further particulars may be obtained from Dr J. R. T. Coutts, Department of Obstetrics and Gynaecology, Royal Maternity Hospital, Glasgow, with whom applications should be lodged by August 30, 1974.

In reply please quote Ref. No. 3530M. (832)

UNIVERSITY OF PITTSBURGH CRYSTALLOGRAPHY DEPARTMENT

Applications are invited for a faculty appointment. Preference will be given to applicants with widely recognised achievements in research pertaining to diffraction and its use for the determination of structure at the electronic, atomic or molecular level. The appointment will be at a rank commensurate with the experience of the successful applicant. Applications should be sent to:

Professor Bryan M. Craven
Crystallography Department
University of Pittsburgh
Pittsburgh, Pa. 15260 U.S.A.

(AN EQUAL OPPORTUNITY EMPLOYER) (834)

UNIVERSITY OF SYDNEY LECTURESHIP IN GEOGRAPHY (three year fixed term appointment)

The Department of Geography requires a lecturer for senior classes in economic geography, and for advising postgraduate students. Candidates should have research and teaching experience, which must include expertise in quantitative techniques. Preference will be given to applicants who can contribute to the Department's interests in resource management and urban and regional planning. Applicants should have a Ph.D. or equivalent qualification. It is hoped that the successful applicant will be able to take up duties early in 1975, but later dates may be negotiated.

The lectureship advertised is for three years in the first instance.

Salary range: \$A9,002 to \$12,352 p.a.

Applications, including curriculum vitae, list of publications, and names of three referees by September 30, 1974 to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information available. Further information also from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. (845)

Bass Charrington Graduate Microbiologist

This interesting and challenging position involves quality control duties at our laboratories at Cape Hill Brewery, Birmingham.

The successful applicant will have an Honours Degree in either Microbiology or a biological subject with substantial Micro-biological content.

We offer an attractive salary, commensurate with the importance we attach to this position, together with the usual fringe benefits associated with a large and progressive organisation.

Apply giving full details to:—

Personnel Manager,
Mitchells & Butlers Limited,
P.O. Box 27,
Cape Hill Brewery,
Birmingham B16 0PQ.

(841)

Senior Physicist

required in the Department of Clinical Physics and Bioengineering. Duties will be to engage in Clinical Radiotherapy Physics, Treatment Planning, Radiation Dosimetry and Radiation Protection. Some teaching in D.S.R. Courses.

Applicants must have a good honours degree in Physics. Clinical experience is essential. Salary scale £2,964 to £3,843 plus £126 London Weighting plus current threshold payment. Application forms obtainable from Personnel Department, Guy's Hospital, London SE1. Tel. 01-407 3662 Ext. 68.

(850)

AGRICULTURAL RESEARCH COUNCIL

LETCOMBE LABORATORY SCIENTIFIC OFFICER

required to fill a vacancy in the Field Studies Department to assist in work on the long term effects of reduced cultivation and direct drilling on soil conditions and crop growth.

Minimum qualifications: Pass degree, H.N.C. or the equivalent in an agricultural or biological science.

Starting salary £1,592 to £1,931 according to qualifications and experience, on scale to £2,675. There is a non-contributory Superannuation Scheme.

Application forms and further particulars may be obtained from the Secretary, Agricultural Research Council, Letcombe Laboratory, Wantage OX12 9JT. The closing date for application is September 20, 1974. (848)

UNIVERSITY OF LONDON KING'S COLLEGE

POSTDOCTORAL ASSISTANTSHIP

Applications are invited for a postdoctoral assistantship in the Department of Pharmacology, for research on neurotransmitter synthesis and turnover. The post is tenable for two years, starting salary according to age and experience, from £2,118 p.a. plus £213 p.a. London Weighting. A knowledge of enzyme purification, immunological, or neurochemical procedures an advantage.

Applications, as soon as possible, to Dr A. K. Prince, Department of Pharmacology (N), King's College, Strand, London WC2R 2LS. (838)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHARMACOLOGY

Applications are invited for two POSTDOCTORAL ASSISTANTSHIPS for work on the mechanism of calcium transport in sarcoplasmic reticulum, or the coupling of hormone receptors to adenylyl cyclase activity, in collaboration with Dr J. C. Metcalfe and Dr G. B. Warren.

Candidates should have research experience in enzymology or physical biochemistry, preferably applied to membranes. The posts are supported by the S.R.C. and the M.R.C. and are tenable for up to three years from October 1974 or later. Salary range £2,223 to £2,553 p.a. (under review) (with F.S.S.U.).

Applications, including curriculum vitae and the names of two referees should be sent to Dr J. C. Metcalfe, Department of Pharmacology, Medical School, Hills Road, Cambridge CB2 2QD, England. (819)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

CHEMICAL ENGINEERING DEPARTMENT SPECIAL RESEARCH ASSISTANT

A vacancy exists for a Research Assistant to work on a Science Research Council research contract to study the condensation of vapours of immiscible liquids. The contract is for a period of three years. The work of the research assistant will entail laboratory studies of condensation, study of the influence of important physical and surface properties, and the operation of a pilot plant experimental rig.

The salary will be within the range £2,383 to £2,746 plus F.S.S.U. contributions. Applications are invited from persons with suitable qualifications or experience in chemistry, physics or chemical/mechanical engineering. Applications should be sent as soon as possible to Dr G. A. Davies, Department of Chemical Engineering U.M.I.S.T., P.O. Box 88, Manchester M60 1QD. (851)

SOUTHAMPTON UNIVERSITY MEDICAL SCHOOL BASIC GRADE BIOCHEMIST

Basic grade biochemist required to work on lipid project in the University Departments of Child Health and Chemical Pathology. The study involves using techniques for lipoprotein electrophoresis, ultracentrifugation and analysis of triglycerides and phospholipids. The successful applicant would be based in the Department of Chemical Pathology and work in close liaison with both clinical and biochemical staff. Applications and enquiries to Personnel Department, Southampton Health District, 119 Tremona Road, Southampton. (843)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF CIVIL ENGINEERING

POSTDOCTORAL RESEARCH ASSISTANTSHIP IN WATER POLLUTION MONITORING

A Postdoctoral Research Assistantship, sponsored by the S.R.C., is available in the Department of Civil Engineering. The research programme involves development of a continuous electroanalytical method for monitoring organic pollutants in effluents. Applicants should have experience of electrochemical and analytical techniques.

The appointment is initially tenable for two years on the salary scale £2,118 per annum rising to £2,247 per annum with F.S.S.U. benefits.

Applications, including curriculum vitae and the names of two referees (quoting R30/74) should be sent to Dr C. L. Page, Department of Civil Engineering, University of Strathclyde, Colville Building, 48 North Portland Street, Glasgow G1 1XN. (874)

Graduate Biochemist/Plant Physiologist

Shell Research Limited, Sittingbourne, Kent have a vacancy for a young graduate biochemist or physiologist in the Biochemistry and Plant Physiology Division of their Milstead Laboratory of Chemical Enzymology. You will be concerned with detailed studies of the regulation of plant metabolic processes and of the enzymes involved. There will be extensive use of radio isotope techniques. You will be expected to have knowledge of and experience in a variety of biochemical techniques. You should have a good Honours degree in Biochemistry or Plant Physiology, and preferably a PhD. Chemistry post-graduates will also be considered if their studies have involved a substantial amount of plant biochemistry and enzymology. The level of appointment will depend upon your background and experience; the salary will be competitive. Please write or telephone for an application form to Shell Research Limited, Recruitment Division (N), PNEL/34, Shell Centre, London SE1 7NA. Telephone 01-934 2948.

AUSTRALIA

New South Wales Department of Agriculture ENTOMOLOGIST

Agricultural Research Station,
Narrabri

Applications are invited for the above position.

Salary :

\$A7,287 per annum range \$A10,953 per annum but Entomologists with post-graduate experience and/or qualifications eligible for payment of salaries up to \$A12,619 per annum. Further progression to higher salaries is available subject to meeting certain specified conditions.

Qualifications :

Degree in Agricultural Science of equivalent but post-graduate qualifications and experience highly desirable.

Duties :

Investigation of insect pests of economic importance to the cotton industry in New South Wales with particular regard to developing suitable integrated pest control measures.

Location :

The successful applicant will be initially located in the Entomology Branch, Biological and Chemical Research Institute, Rydalmere, Sydney, for a short period before subsequent location at the Narrabri Agricultural Research Station.

Subject to certain conditions the successful applicant will be eligible for:—

Payment of fares to Sydney

Financial assistance towards cost of removal expenses

Financial assistance
towards cost of initial accommodation expenses

For further information and application form telephone or write to the Recruitment Section, New South Wales Government Offices, 66 Strand, London WC2N 5L $\frac{1}{2}$ (Tel: 01-839 6651 Extension 194) where applications close on FRIDAY, 27th SEPTEMBER, 1974. When telephoning or writing please quote reference 44/570.

(884)

ANTARCTIC EXPEDITION

requires an OBSERVATORY PHYSICIST to serve at British stations in Antarctica. The tour of duty covers two Antarctic winters involving an absence from the United Kingdom of about 2 $\frac{1}{2}$ years. The successful applicant will be required to work on his field data for up to a year after his return.

Qualifications: Preferably a First or Upper Second Class Honours degree but an ordinary degree with experience or appropriate H.N.D. will be considered.

Starting salary from £1,793 per annum rising in scale to £2,889 per annum. Low income tax, free messing, bonus for satisfactory service.

Applicants must be single and aged 22 to 30.

If you are interested in seeing a largely unknown, remote and fascinating part of the world, please write to:

The Establishments Officer,
British Antarctic Survey,
30 Gillingham Street,
London SW1V 1HY.
Tel: 01-834 3687.

(869)

UNIVERSITY COLLEGE DUBLIN APPOINTMENT IN AGRICULTURAL CHEMISTRY

Applications are invited for a teaching post either as:

- (a) COLLEGE LECTURER, or
- (b) ASSISTANT LECTURER

in the Department of Agricultural Chemistry. Candidates should be Graduates in Agricultural Chemistry, Chemistry, Biochemistry, Microbiology or Agricultural Science, with a Ph.D. and preferably with some teaching and research experience.

The current salary scales are:

College Lecturer £3,514 by £162 to £4,648
Assistant Lecturer £2,420 by £129 to £3,323.

Entry point on the relevant scale will be in accordance with qualifications and experience.

A non-contributory pension scheme and family allowances are additional to salary. An alternative contributory F.S.S.U. type scheme is also available.

Prior to application, further information (including application procedure) should be obtained from:

Mr J. P. MacHale,
Secretary and Bursar,
University College,
Belfield,
Dublin 4.
Telephone 693244 Extn. 431.

Latest date for receipt of completed application is September 16, 1974. (840)

UNIVERSITY OF GLASGOW DEPARTMENT OF BOTANY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a Postdoctoral Research Assistantship in the Department of Botany to work on an S.R.C. sponsored research programme concerned with the hormonal regulation of nitrogen fixation in higher plants. Preference will be given to applicants with previous experience of the biochemistry and/or physiology of plant growth hormones.

The appointment will be for one year in the first instance, from October 7, 1974, and the starting salary will be not more than £2,118 per annum plus F.S.S.U. benefits.

Applications, with curriculum vitae and the names of two referees, should be sent not later than September 6, 1974, to Dr C. T. Wheeler, Department of Botany, University of Glasgow, Glasgow G12 8 QQ.

In reply please quote Ref. No. 3532M. (854)

UNIVERSITY OF THE WEST INDIES TRINIDAD

Applications are invited for (a) LECTURESHIP or ASSISTANT LECTURESHIP IN CROP PRODUCTION in the Department of Crop Science, tenable from January 1975. Applicants should possess a higher degree in Agriculture or Plant Science, and experience in teaching and research on tropical crops. Experience in management of plantation and field crops in the Caribbean area is considered desirable but not essential. Salary scales: (a) TT\$12,612 to TT\$20,316 p.a. (b) TT\$10,200 to TT\$11,232 p.a. (£1 sterling=TT\$4.8), F.S.S.U. Unfurnished accommodation at rental of 10% of salary. Thereafter 20% of salary paid in lieu of housing. Family passages; study leave. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible, to the Secretary, University of the West Indies, St Augustine, Trinidad. Detailed particulars of the post will be sent to all applicants. (819)

UNIVERSITY OF QUEENSLAND AUSTRALIA

ONE LECTURER AND ONE SENIOR TUTOR IN EXPERIMENTAL PHYSICS

Applicants with experience in one of the following areas will be preferred: Beam foil spectroscopy; environmental (hydrodynamic modelling) physics; ionospheric physics; microwave and molecular physics.

Salary: Lecturer within the range \$A9,002 to \$A12,352 per annum; Senior Tutor within the range \$A7,545 to \$A9,002 per annum.

Other Benefits: Superannuation similar to F.S.S.U., housing assistance, and travelling and removal expenses. Lecturer also entitled to study leave.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in London and in Brisbane on September 30, 1974. (856)

UNIVERSITY OF LONDON GRANTS FOR RESEARCH

Applications are invited from members of the University and teachers in Schools of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus. Grants are not made for normal maintenance. Applications must next be received not later than September 15. Forms of application and further particulars may be obtained from the Secretary to the Central Research Fund, University of London, Senate House, London WC1E 7HU. (846)

UNIVERSITY OF DUNDEE DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

Applications are invited for a RESEARCH ASSISTANTSHIP in the Department of Therapeutics at Ninewells Hospital, Dundee.

The appointment, which will be for three years, will involve work in a research project on the effect of drugs on red blood cells and the protective effects of the enzyme systems.

The candidates should possess a good Honours Degree in Biochemistry. The initial salary will be £1,680 per annum.

Informal enquiries may be made to Dr G. R. Tudhope, Department of Therapeutics, Ninewells Hospital, Dundee DD2 1UD.

Applications, quoting Ref. EST/53/74J, together with a curriculum vitae and the names of two referees, should be sent to The Secretary, The University, Dundee DD1 4HN, by September 13, 1974. (847)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF MICROBIOLOGY LECTURER

High academic qualifications required, together with training, research and teaching experience in the general field of microbiology. Appointee will participate in a number of microbiology courses offered to science, food technology and medical students.

Salary: \$A9,002 range \$A12,352 per annum. Commencing salary according to qualifications and experience. Appointment to commence during February 1975.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on September 20, 1974. (857)

PUBLIC HEALTH LABORATORY AND DEPARTMENT OF MICROBIOLOGY CENTRAL MIDDLESEX HOSPITAL Park Royal, London NW10 7NS

VIROLOGY TECHNICIANS

required to work in a new microbiology laboratory. There are excellent facilities for routine and research work in this well equipped laboratory which includes an ultra centrifuge and electron microscope.

Applicants should possess a H.N.C. or equivalent qualification, but experience in virology is not essential. The successful applicant will be encouraged to study for the advanced examination in virology.

Whitley Council salary and conditions. Apply in writing to the Director, Dr C. E. D. Taylor. (867)

WEST BERKSHIRE HEALTH DISTRICT MEDICAL PHYSICS TECHNICIAN

for the modern Isotope Laboratory at the Royal Berkshire Hospital, Reading, for interesting work in the chemistry and physics of medical isotope techniques. Post will be on Grade V or Grade IV (£1,308 to £1,667 or £1,530 to £1,953). Day release for further training possible. (Normally O.N.C. or 2 'A' levels required.)

Reading is a pleasant University town offering easy access to London, Oxford, Windsor, Henley and attractive surrounding countryside.

Written applications with relevant details and naming 2 referees to Hospital Secretary, Royal Berkshire Hospital, London Road, Reading. (862)

UNIVERSITY OF BRISTOL LONG ASHTON RESEARCH STATION SCIENTIFIC OFFICER

required to work in the Microclimatology Section. Applicants should have some knowledge of environmental physiology, cropping systems and scientific instrumentation. Part of the work will be done in France. Qualifications: Pass Degree, H.N.C. or equivalent. Salary in scale £1,592 to £2,675 according to qualifications and experience, with non-contributory superannuation scheme.

Applications by September 25 to Secretary, Research Station, Long Ashton, Bristol BS18 9AF, who will provide further particulars of the post. (839)

POLYTECHNIC OF THE SOUTH BANK

FACULTIES OF SCIENCE AND ENGINEERING

RESEARCH ASSISTANTS

Applications are invited for posts in the following areas of work:

Ionisation of Gases.

Polymer Science (Organo-Silicon Polymers, physical and chemical properties of polymers, or polymerisation processes).

Chemistry (Peptide Chemistry or Organo-Metallic Chemistry).

Control Engineering (stochastic processes applied to the optimisation of industrial control systems).

High-voltage Engineering (mechanisms of dielectric breakdown by discharge and use of non-destructive tests for electrical insulation).

Applicants should be graduates in appropriate subjects, who wish to take a higher research degree.

Appointments are normally for three years on a salary scale currently:

£1,648.40 to £1,758.40.

Application forms and further details from the Clerk to the Council (Room 720), Polytechnic of the South Bank, Borough Road, London SE1 0AA. Tel. 01-928 8989. (865)

UNIVERSITY OF READING DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

RESEARCH DEMONSTRATORS

required to do research for a higher degree in the following areas:

(a) with Dr B. A. Nicholson on the structure and functions of RNA Polymerase;

(b) with Professor G. M. H. Wailes on the metabolic control and endocrinology of the mammalian testis and epididymis.

Candidates should have a good Second Class Honours Degree in a relevant subject. The posts will be for three years with the possibility of extension and involve about 12 hours demonstrating per week during term time. Salary £1,122 by £54 to £1,230 p.a. plus threshold payment.

Apply with names of two academic referees to Professor G. M. H. Wailes, Department of Physiology and Biochemistry, The University, Whiteknights, Reading RG6 2AJ, or ring Reading 85123 extn. 7675. (Ref: TN70). (864)

UNIVERSITY OF RHODESIA FACULTY OF SCIENCE

LECTURESHIP IN ANIMAL NUTRITION

Applications are invited for the post of Senior Lecturer or Lecturer in Animal Nutrition in the Department of Agriculture. Candidates should have at least an honours degree in Biochemistry or Agricultural Science, together with relevant research experience and knowledge of animal nutrition. A special knowledge of ruminant nutrition would be of substantial advantage.

Salary Scales (Approx. Stg. equivs.): Senior Lecturer: £5,484 by £219 to £7,239; Lecturer Grade I: £4,984 by £184 to £5,720; Lecturer Grade II: £3,071 by £158 to £3,545 by £175 to £3,895 by £185 to £4,635 by £174 to £4,809.

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid schemes.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications, and naming three referees, should be submitted by September 30, 1974, to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Applicants from outside Southern Africa should send a copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. (855)

THE UNIVERSITY OF MANCHESTER Institute of Science and Technology DEPARTMENT OF OPHTHALMIC OPTICS ANIMAL TECHNICIAN

(GRADE 4)
(Ref. O/128/AI)

Applications are invited for the post of Animal Technician in the Visual Sciences Laboratories of the above department.

Duties will involve the care of a variety of animals including monkeys, assistance with research involving animals and organisation of breeding programmes.

In addition some assistance with physiological demonstrations will be required.

Appropriate experience is essential and membership of the Institute of Animal Technicians is desirable.

Salary scale, according to age and experience will be £1,848 to £2,163.

Forms of application are obtainable from the Registrar, U.M.I.S.T., P.O. Box 88, Sackville Street Manchester M60 1QD, to whom completed forms should be returned by September 13, 1974. (842)

HISTOLOGY TECHNICIAN

required by private company carrying out a wide variety of diagnostic and experimental pathology. A.I.M.L.T. or similar qualifications. MICROBIOLOGIST also required to head department. Applications in writing to The Personnel Manager, Wickham Laboratories Limited, Winchester Road, Wickham, Hants PO17 5EU. (825)

SOUTH WEST THAMES REGIONAL NUCLEAR MEDICINE CENTRE, ROYAL MARSDEN HOSPITAL, DOWNS ROAD, SUTTON, SURREY

SCIENTIST

required to take part in a multi-disciplinary study of radiopharmaceuticals used to localise tumours and study their metabolism. Candidates who should be graduates in a physical or biological science will be expected to undertake some routine work within this large modern and well-equipped department. Salary is (basic scientist grade). Details of qualifications, age and experience should be sent with the names of two referees to Miss I. Mayor, Deputy Administrator, Royal Marsden Hospital, Downs Road, Sutton, Surrey. (831)

BIOCHEMIST or CELL BIOLOGIST, SWEDEN

Pharmacia Fine Chemicals AB, manufacturers of Sephadex^R and other products for biochemical separations, require a biochemist or cell biologist to work at our headquarters in Uppsala, Sweden.

The successful applicant will join our Scientific Information and Technical Services group. The activities of the group include

- ★ the preparation of all kinds of scientific information material
- ★ applications work and laboratory testing of new products
- ★ lecturing

but applicants should be prepared for extremely varied work and certain amount of travelling, mostly within Europe.

Applicants should have research experience in biochemistry or cell biology. Clear and accurate expression in the written word is essential with English as the Mother tongue.

This is an important position and carries an appropriate salary. Preferred age 25 to 30.

Write in confidence to:

Mr D. Sweetman
Pharmacia (Great Britain) Ltd
Paramount House
75 Uxbridge Road
London W5 5SS

Pharmacia
Fine Chemicals

(885)

THE POLYTECHNIC OF NORTH LONDON

Holloway, London N7 8DB

Applications are invited from graduates with a good Honours Degree for appointment as RESEARCH ASSISTANT to work in the field of Cytogenetics (with special reference to polymorphic gastropods). The successful candidate will be expected to read for a higher degree. The post will commence in January, 1975.

Salary scale: £1,544 by £55 by £1,654.

Apply in writing, stating qualifications and the names of two referees, to: Head of Department of Biology, The Polytechnic of North London, Holloway Road, London N7 8DB. (866)

RESEARCH SCIENTIST (BIOCHEMISTRY)

Ref: RES/73/7
(RE-ADVERTISED)

Qualifications: Ph.D. degree in biochemistry immunology or physiology. Experience with investigations in insect science would be an advantage. This position is open to young postdoctoral scientists who have interest in immunology, enzyme biochemistry, or immunochemistry.

Responsibilities: The successful candidate will be required to collaborate in the investigation of the tsetse salivary gland physiology and its relationship to the immunology of resident trypanosomes.

Salary: Not less than 44,000/-.

Other benefits include a ten per cent gratuity of basic salary, a house allowance and medical insurance.

Date of appointment: Immediate.

Applications, in six copies, should give the following information: General education. Professional qualification, experience, marital status, age, present salary and terms of service, and names and addresses of four referees (including a personal reference). Photostat copies of relevant transcripts, thesis abstracts and certificates should be enclosed.

Applications should be addressed to:

The Administrative Officer
ICIPE Research Centre
P.O. Box 30772,
NAIROBI, Kenya.

(863)

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF GENETICS LECTURER

Candidates should have suitable qualifications and experience in some branch of Genetics. The Department already has appointments in microbial genetics, population genetics and cytogenetics and preference may be given to applicants who are qualified in one or another of these aspects of Genetics. The successful applicant will be expected to initiate and supervise research and conduct classes in the general area of his specialty as well as assisting in the general teaching programme of the Department.

Salary Scale: \$A9,002 to \$A12,352 per annum with superannuation based on an endowment assurance scheme the employee and employer contributing 5% and 10% respectively.

Benefits: Travelling expenses for appointee and family; removal allowance; repatriation after three years appointment if desired; temporary housing for an initial period; availability of loans for home purchase; study leave entitlement accumulates at the rate of one month's leave for each six months' service up to six years, with provision for financial assistance.

Further general information and details of application procedure are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia, or the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Enquiries about departmental research interests and facilities to Professor B. W. Holloway in the University.

Closing Date: **September 30, 1974.**

The University reserves the right to make no appointment or to appoint by invitation. (873)

NORTH MIDDLESEX HOSPITAL CLINICAL CHEMISTRY DEPARTMENT

Applications are invited from graduates in Biochemistry, Physiology or Chemistry or a vacant post in this department.

The post will provide wide experience in routine hospital work, and will allow opportunity to develop methods in a specialist field such as lipoprotein investigations, radioimmunoassay or steroid Chemistry.

Applications or enquiries should be sent to: Dr Dangerfield, North Middlesex Hospital, Silver Street, Edmonton, London N18 1QX. (870)

M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital)

Watford Road, Harrow, Middlesex HA1 3UJ.
The Division of Psychiatry requires a BIO-CHEMICAL PHARMACOLOGIST with post-graduate experience to join a team of clinicians and biochemists working on metabolic disturbances in the functional psychoses and the mode of action of psychotropic drugs. It is intended that the candidate appointed will develop a particular interest in the metabolism of psychotropic drugs but may also collaborate in projects on mechanisms of action. An interest in developing new assay techniques would be an advantage. Conditions of service in accordance with M.R.C. regulations. Salary depending upon age and experience.

Further details and application forms may be obtained from Mrs J. Tucker-Bull.
Please quote ref. 125/1/Y5. (871)

HISTOLOGY TECHNICIAN

required for Pharmacological and Toxicological Laboratory. Experience essential in the preparation and processing of animal tissues.

Good working conditions. Pension and Assurance Scheme. Application forms from:

The Secretary, Biorex Laboratories Ltd.,
Biorex House, Canonbury Villas, London N1 2HB. (876)

UNIVERSITY OF MELBOURNE LECTURESHIP (Limited Tenure—Three Years)

in the
DEPARTMENT OF PHYSIOLOGY

This appointment is to be made to assist in the development of a neurosciences training programme within the Department of Physiology. In this programme we aim to provide a co-ordinated course of study of the functions of the brain (in physiological terms). The course commences in the third year of the science course, continues through the honours year and also provides supervision of research activities and course work for postgraduate M.Sc. and Ph.D. students. The appointee will participate in this programme together with four other staff members. A separate neurophysiology laboratory is to be used for laboratory work for undergraduate students, but postgraduate students will work and be supervised in the research laboratories of the Department.

The research facilities available in the Department for the study of brain function have recently been considerably expanded with the setting up of a sensory processes laboratory (I. Darian-Smith and K. O. Johnson). Neurophysiology and experimental psychology laboratories of this unit provide facilities for correlative studies of cutaneous sensibility and the underlying neural events as observed in human subjects and monkeys. Each laboratory has independent access to a PDP11/40 computer system. In a second research laboratory, also with computer facilities, functions of the limbic system are being studied (J. S. McKenzie) by correlating neural events with motivated behaviour.

Applicants should have teaching and research experience in neuro-science and either a Ph.D. in this field, or an equivalent qualification.

Salary: \$A9,002 to \$A12,352 (US\$13,360 to US\$18,300 as at July 26, 1974).

Commencing Date: January 1, 1975 or as soon as possible thereafter.

Further details may be obtained from Professor I. Darian-Smith, Department of Physiology in the University. Details of application procedure together with conditions of appointment may be obtained from the Registrar, University of Melbourne, Parkville, Victoria 3052, Australia, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications close on September 20, 1974. (872)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF BIOCHEMISTRY RESEARCH STUDENTSHIP IN PHYSICAL BIOCHEMISTRY

Applications are invited from honours graduates in Chemistry and Biochemistry for studies on the physical biochemistry of enzymes. The nature of the award will be equivalent to an S.R.C. Studentship and the candidate will be able to register for a Ph.D. degree.

Applications giving curriculum vitae and the names of two referees should be sent by August 31 to Superintendent, Department of Biochemistry, Tennis Court Road, Cambridge CB2 1QW.

(X664)

HERIOT-WATT UNIVERSITY DEPARTMENT OF CHEMISTRY

Applications are invited from persons holding good honours degrees in Chemistry for an S.R.C. (C.A.S.E.) RESEARCH STUDENTSHIP in liaison with Nuclear Enterprises, Edinburgh. The studentship, tenable for three years, is available from October 1, 1974. The successful candidate will register for the degree of Ph.D. and will work under the joint supervision of Dr. I. Soutar and Dr. W. Steedman. The project is concerned with various aspects: the efficiency of plastic scintillator materials and will involve both the formulation of novel plastic scintillator systems and their evaluation using fluorescence and other techniques and will provide a broad experience in polymer chemistry research.

Applications should be sent to Dr W. Steedman, Department of Chemistry, Heriot-Watt University, Riccarton, Currie, Edinburgh EH14 4AS, from whom further information may be obtained. (860)

THE ROYAL MARSDEN HOSPITAL Fulham Road, London SW3

Applications are invited for a ROYAL MARSDEN FELLOWSHIP for training and research in Clinical Immunochimistry as related to malignant disease. Suitable for persons wishing to pursue a career in Clinical Oncology or Pathology.

Arrangements have been made for successful applicant to take the M.Sc. Course in Immunology at Birmingham starting October, 1974, and then to spend two years in the Division of Tumour Immunology of the Institute of Cancer Research at Sutton, Surrey.

Salary on Registrar Scale (£3,198 to £3,879) (Non-resident post).

Application forms are available from the Deputy House Governor at the above address (telephone 352 8171 ext. 205) to whom they should be returned by September 9, 1974. (880)

APPLIED PLANT PHYSIOLOGY CAMBRIDGE UNIVERSITY DEPARTMENT OF APPLIED BIOLOGY

invites graduates in Botany, Agricultural Botany or other relevant subject to apply for a Ministry Postgraduate Agricultural Research Studentship tenable from October 1974 to extend research on the physiological basis of varietal differences in yield in oil seed rape. Applications with full personal particulars and names and addresses of two referees should reach the Secretary, Department of Applied Biology, Downing Street, Cambridge not later than August 30, 1974. (853)

UNIVERSITY COLLEGE DUBLIN FACULTY OF AGRICULTURE POSTDOCTORAL FELLOWSHIP or RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral fellowship or research assistantship position sponsored by the National Science Council to study aspects of nitrogen fertiliser use by crops.

Applicants should have an honours degree in agricultural science, chemistry, biochemistry or microbiology. The initial appointment, which commences on October 1, 1974, will be for one year with the probability of renewal for a further two years. Salaries will commence at £2,106 for post-doctoral fellowship and £1,395 or £1,670 depending on qualifications for research assistant.

Applications, giving details of education and experience, should be sent before August 30 to: Dr M. A. Morgan, Dept. of Agricultural Chemistry and Soil Science, University College Dublin, Faculty of Agriculture, Glasnevin, Dublin 9. (852)

UNIVERSITY OF EXETER DEPARTMENT OF CHEMISTRY

Applications are invited for an S.R.C. supported POSTDOCTORAL RESEARCH FELLOWSHIP for structural studies of nematic liquid crystals by X-ray diffraction. The appointment is for up to two years at a salary of up to £2,247 with superannuation benefits, depending on age and experience. The Research Fellow will join a group working on the structure and dynamics of disordered solids and ordered liquids by X-ray and inelastic neutron scattering techniques. Some background of scattering work, crystallography, spectroscopy or computing would be advantageous.

Applications, with the names of two referees, should be sent, as soon as possible, to The Secretary of the University, Northcote House, The Queen's Drive, Exeter, by October 1, 1974. Please quote reference 1/12/7082. The successful applicant may take up the post at any time up to January 1975. (818)

UNIVERSITY OF HULL DEPARTMENT OF PLANT BIOLOGY

Applications are invited for the post of Post-doctoral Fellow in Plant Biochemistry, to work with Professor J. Friend and Dr D. R. Threlfall on the molecular structure of potato cell walls in relation to pathogenesis. The post is financed by the A.R.C. and is tenable for up to three years from October 1, 1974, or as soon as possible thereafter.

Salary (excluding threshold payments) will be on the scale £2,226 by £114 to £2,340 by £72 to £2,412, plus F.S.S.U. benefits.

Applications (three copies) giving details of age, qualifications and experience together with the names of two referees should be sent by September 9, 1974 to the Registrar, The University of Hull, Hull HU6 7RX from whom further particulars may be obtained. (833)

Philipps-Universität Marburg/Lahn, West Germany

A temporary professorship (H2, ca. 3.100,—DM monthly) for Crystallography is available from October 1, 1974 to September 30, 1976 with the possibility of extension till September 30, 1978.

Applicants will be required to work in one of the fields of theoretical crystallography, structure determination methods or theoretical solid state research, and should be able to teach in these fields. In addition, they would be requested to give an introductory course in statistical methods for geoscientists. The holder of the professorship is a member of the Sonderforschungsbereich "Kristallstruktur und chemische Bindung".

Applicants with corresponding scientific qualifications and teaching experience are invited to send in their application (curriculum vitae, giving in particular details of their scientific career and previous teaching activity; list of publications, with a selection of important reprints) to the Dean, Fachbereich Geowissenschaften der Philipps-Universität, 355 Marburg/Lahn, Lahnberge, before September 15, 1974.

(858)

OPTICAL FIBRE COMMUNICATIONS

Communication by optical fibres is a rapidly expanding new technology which is being widely taken up by industry. The Laser research group at Southampton, comprising some 15 research workers, has been engaged in this field for some years with support from Science Research Council, industry and elsewhere. We have already announced world records for low transmission loss and high bandwidth in our fibres and wish to expand the present research team. Applications are therefore invited for a number of research fellowships, including a Pirelli Fellowship for work in collaboration with industry, at salaries linked to the scale for Lecturers in the range £2,118 to £3,462 plus threshold payments. Persons with an interest in any aspect of the subject are eligible. Applications giving details of education, experience and the names of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH. Please quote reference No. 231/R.

(734)

UNIVERSITY OF ABERDEEN

UNIT FOR RESEARCH ON ADDICTIVE DRUGS

A S.R.C. Studentship (Co-operative Award in Science and Engineering, C.A.S.E.) will become available on October 1, 1974. It is tenable for 3 years in co-operation with the Pharmaceutical Division of Reckitt and Colman Ltd., Hull, and is open to First and Upper Second Class Honours Graduates in Pharmacology, Biochemistry or Physiology. The research project is concerned with the action of newly-synthesised morphine-like compounds on neurotransmitter release and on behavioural patterns in normal and morphine-dependent animals.

Applications (3 copies) to be submitted to Professor H. Kosterlitz, Unit for Research on Addictive Drugs, University of Aberdeen, from whom further particulars may be obtained, Marischal College, Aberdeen AB9 1AS, not later than September 6, 1974.

(789)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CHEMICAL ENGINEERING AND FUEL TECHNOLOGY FIRE RESEARCH

Applications are invited for the post of RESEARCH FELLOW to work with Dr D. J. Brown on BEHAVIOUR OF WOOD AND PLASTICS IN FIRES. The Fellowship, which will be available for 3 years, is financed by a grant from the Fire Research Station, Department of the Environment. Salary: on a scale up to £2,412 per annum according to qualifications and experience. Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN, to whom applications (2 copies) should be sent by October 1, 1974. Please quote reference R127/G.

(809)

ROWETT RESEARCH INSTITUTE BUCKSBURN ABERDEEN

Applications are invited from Zoologists, Biochemists or others from appropriate disciplines to take up a 3-year A.R.C. STUDENTSHIP to study the amino acid requirements of insects and other organisms with potential as assay systems for food protein quality. A first or upper second class degree is required and the successful candidate will be expected to register with the University of Aberdeen for the Ph.D. degree.

For further information, those interested should apply as quickly as possible, by telephone or letter, to: The Secretary, Rowett Research Institute, Bucksburn, Aberdeen AB2 9SB. Tel: Bucksburn (0224-71) 2751.

SUBSCRIPTION — REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of a twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me:

1 NATURE BINDER (I enclose £1.85)

3 NATURE BINDERS (I enclose £5.00)

(Payment may be made in any currency at the current rate of exchange)

Prices applicable only to orders received before the 30th June 1975.

Orders can only be serviced if accompanied by remittance, cheques should be made payable to Macmillan Journals Limited.

The intriguing tale of the fat mouse.

1,1'-BIS-(2-CHLOROETHYL)-4,4'-BIPIPERIDINE (BPM)

BPM was prepared during work on antileukemic drugs.^{1,2} When incubated in 0.1M borate buffer, pH 9, at 37° for 1 hr., and then injected intraperitoneally into female mice weighing 20g, **BPM** caused intoxication and loss of weight for 3 to 6 days, followed by rapid accumulation of lipid for 2 to 3 weeks, producing a weight gain of up to 20g. A maximum of 60 to 70g (3 to 4 times the normal weight) was reached in 3 to 4 months after injection.³ The rate of increase in weight and the final body weights were proportional to the dose in the range of 5 to 50mg/kg.³ **BPM** without incubation was inactive; its activation was attributed to the formation of a bicyclic ethylene immonium compound.³ The action of **BPM** was antagonized by *N*-acetylcysteine,³ as had also been found for gold thioglucose,⁴ and resembled gold thioglucose in the induction of hypothalamic lesions.^{3,5} The metabolic effects of **BPM** have been investigated.⁶ The immonium form of **BPM** inactivated double and single stranded DNA and RNA phages, presumably by forming inter- and intrachain cross-links.⁷ **BPM** increased the concentration of growth hormone and of prolactin in the pituitary glands and increased the weights of pituitary and adrenal glands, ovaries and uteri of mice in addition to causing obesity.⁸

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 300 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Should scientists be re-auditioned?

In general artists live by their wits and survive through being productive. If they are painters they must continue to paint and sell. If they are musical performers they must continue to keep a high standard of performance—in an orchestra that will mean a regular re-audition. It is a ruthless existence and yet one about which few of those involved in it, or even those who were once involved in it and have been left behind, feel bitter. There is often a feeling that the state should support an orchestra, an art gallery, a theatre, but rarely do individual creative or performing artists reckon that the state owes them a living. Indeed it is thought quite natural that they should move into teaching when they find their other abilities waning, without in any sense regarding teaching as an inferior profession.

What is it about scientists and the scientific profession which makes the idea of something even remotely similar amongst themselves unthinkable? In certain trades and professions it is possible to point to an accumulation of worldly goods which prevents any major changes in course—a taxi-cab, a workbench and tools, dental equipment. In others, more experience makes for greater capability as time goes on. Politicians, priests, bartenders probably feel that way. But a scientist neither owns his tools (beyond a relatively few books and journals of current use to him) nor demonstrably improves with age, unless he be in the business of cataloguing or collecting. Why then should he dig in for life, as he is very prone to?

One reason, of course, is that it is a very pleasant life, involving lots of travel, and in terms of service many scientists are near to being self-employed without the financial responsibilities that self-employment involves. Another is that the outside world seems to offer a great deal less stability, if it offers anything at all. Yet another is that scientists often delude themselves that it is creditable to go on working on the same old problems, gradually chipping them away, when the very last thing that most scientific problems need is the attention of one man, often to the exclusion of others, for thirty to forty years.

The community of older scientists must inevitably continue to grow for the foreseeable future and at some time governments, industry and academe are bound to have to ask whether the ranks of an ageing workforce can be allowed to continue to swell. This question is indeed being faced now by many institutions, world-wide, which sprang up in response to immediate post-war, defence needs. Academics can maybe justify themselves by increased teaching and administrative loads and a growing involvement in maintaining the standards of

the college wine cellar. Others have no such outlets unless they are specifically plucked out of 'science' and dropped into 'administration'; and this is said to be a move that few are allowed to make.

There is a case, then, for scientists to come up with some fairly concrete proposals on the employment of older members of the profession before the government or other large scale employers step in with their own schemes for thinning the ranks. And perhaps some sort of re-auditioning system should be discussed in conjunction, of necessity, with an extensive rethinking of the career structure of scientists. It is obviously pointless to urge or even force someone out of his laboratory without any guarantee that other jobs can be found which do not involve a humiliating change.

If at the present this is not so, then it is time that scientists as a community started talking seriously about their prospects. It is only depressing that in Britain at present there is not a suitable forum for this, although we suggest elsewhere in this issue (page 743) that the British Association ought to become a gathering of thoughtful scientists. Then ultimately it should be possible to approach the government with rather specific proposals that every year a substantial number of intelligent, well trained and experienced men would be available at ages between, say, 35 and 50 for redeployment—and what could be available within the public and educational sector? The answer would, of course, be nothing, but a start would have been made in asking important questions about skilled manpower. It is impossible to believe that in reality such men are unemployable when there is an apparent shortage of intellect all around.

Many scientists would, we believe, welcome the opportunity to use formal review points in their career, perhaps every five years between 35 and 50, to make a sideways step as a means of self-regeneration. In that way the audition could almost be a self-audition. But they should not expect jobs to be waiting for them unless they have done a lot of hard lobbying first.

A hundred years ago

ON Friday evening M. Flammarion, the French astronomer, started from La Villette gas-works, Paris, in a balloon called *Lumen*, at half-past seven, with a brisk breeze from the north-west. The balloon was under the guidance of M. Jules Godard, and M. Flammarion, who was married in the beginning of August, was on board with his young wife; he wishes to spend his *lune de miel* in Italy. Such a trip was proposed in the beginning of the century to the celebrated M^{de} de Stael by the great philosopher, Saint-Simon; but the lady declined. The moon was full and bright.

From *Nature*, 10, 360, September 3, 1874.

international news

THE community of nations has gathered for the third time to develop a new order in the sea. What in 1967 started as a limited exercise to establish a regime for the seabed and the ocean floor beyond the limits of national jurisdiction, has developed into a formidable project whose objectives are to revise the whole philosophy of the law of the sea in an attempt to redress the balance between developing and developed countries. It is 15 years since the completion of the four 1958 Geneva Conventions which tried to establish rules for the use of the seas and now, after a very short interval, even their essential postulates are in question.

The old principle of the freedom of the seas which basically asserts that all States have equal rights to use the seas and which stood solid as a rock for more than 350 years is the object of serious attacks—the most dramatic change taking place is in the breadth of the coastal area over which various States claim sovereignty or jurisdiction; this may extend to 200 nautical miles (370 km) or to the outer edge of the continental rise if this feature goes beyond the 200 nautical miles. If this claim is accepted, more than 30 per cent of what today is high seas and which enjoys the freedom established in the 1958 Geneva Convention on the High Seas will come under the jurisdiction of coastal States—foreign vessels will have only the right of “innocent passage”. The other rights, including the one to conduct scientific research will disappear under this new concept.

The main battle at the Caracas Conference is being fought in the Second Committee where the right of coastal States to establish an exclusive “economic zone” or “patrimonial sea” beyond its territorial sea is under consideration. At the time of writing, about 20 days from the end of the Conference, there are the following tendencies on this matter:

(1) Territorial sea

- States which claim 12 nautical miles. The great majority of countries support this, but only if an economic zone of 200 nautical miles is accepted. This territorial sea of 12 miles, say the major maritime powers, may not impede transit through straits used for international navigation;

- States which claim 200 nautical miles; Brazil, Ecuador, Panama, Peru, Somalia, Uruguay.

(2) Economic zone or patrimonial sea

- States which claim an economic zone beyond the 12 miles’ territorial sea

Report from Caracas

extending to 200 nautical miles enjoying exclusive rights on exploration, exploitation and management of living and non-living resources; on prescribing standards for the preservation of the marine environment; and on the regulation of scientific research: Argentina, Australia, Canada, India, Kenya, Mexico, Tanzania, Venezuela and many others.

- States which accept 200 nautical miles economic zone but with certain conditions: (1) the coastal State will not necessarily have exclusive rights to living resources; that in order to ensure the full utilisation of living resources an obligation must be put on the coastal State to allow other States access to the resources which they do not utilise; (2) that the coastal State may enforce pollution standards agreed upon internationally but may not itself prescribe those standards unilaterally; (3) that the consent of a coastal State is not required to conduct scientific research once the vessels of other countries meet certain specified obligations.

(3) Definition and delimitation of continental shelf

The difference is between those States wishing to include the continental shelf in an economic zone of 200 nautical miles and those States like Argentina, Australia, Canada, which will prefer to go beyond 200 miles to the outer edge of the continental rise if this is larger than 200 miles.

(4) High seas and international seabed area

The need for a Seabed Authority is being accepted by the majority of States but they differ on the role to be assigned to such an Authority. A great number of developing States want to empower it with the management of living and non-living resources as well as the protection of the marine environment and regulation of scientific research. The great maritime countries want to endow the Seabed Authority with responsibility for the administration of the exploitation of the Seabed resources only. The system of exploitation, conditions of exploitation, machinery, and economic implications of exploitation remain to be solved.

The specific problem of marine scientific research and transfer of tech-

nology is being dealt with in Committee III. Here the discussions have concentrated on the definitions and objectives of marine scientific research, and the conduct and promotion of marine scientific research, including the right to conduct, granting of consent, participation and obligation of coastal States, and the general conditions for the conduct of marine research.

It is generally accepted that the proper management of the marine environment and its resources depends upon knowledge of the sea—however, management-orientated research is generally considered to be applied in nature; consequently the developing countries feel very strongly about the need to regulate such research, not only in the economic zone but also in the international sea. They feel less strongly about pure scientific research; but it is very difficult, if not impossible, to distinguish between pure research and economic or military research.

The general tendency (particularly within the developing countries) is to regulate scientific research in the territorial sea and economic zone. Consent can be refused in the territorial sea but in the economic zone “shall not” or “may not” be withheld if some specified conditions are met. The stronger “shall not” is proposed by Ireland and “may not” by Mexico. These conditions are very similar to those recommended by the International Council of Scientific Unions (ICSU) in its statement on freedom of scientific research and also the conditions being met within the International Decade of Ocean Exploration of the Intergovernmental Oceanographic Commission.

The conditions to be met can be summarised as follows:

- (a) Participation by developing countries in all phases of the work (from planning to the final results). This condition is directly related to the problem of development and transfer of technology, about which developing countries feel strongly.
- (b) Collected data and samples, as well as written up results, be made available as soon as possible to the coastal State.
- (c) That the research is being conducted for peaceful purposes.

The present discussions seem to indicate that there is complete agreement on the need to establish a viable framework for the conduct of marine scientific research. □

Oil platform question still confused

by Eleanor Lawrence

THE British government has finally decided that some sort of planning policy is necessary to solve the vexed question of where in Scotland to build concrete gravity-type oil production platforms. But the statement may raise more problems than it solves.

Mr Eric Varley, Secretary of State for Energy, proposes that a limited number of future sites should be taken into public ownership in order to:

- maximise their use
- avoid proliferation of sites
- ensure only the minimum amount of infrastructure (such as roads and housing) is built
- make sites available in good time for the best platform designs
- enable strict control to be exercised over the development and eventual restoration of the sites.

But Mr Varley also emphasises that normal planning controls and procedures will not be by-passed, and in this his proposals differ from those of the last government which proposed to short-circuit planning procedures but not to acquire the land.

It is difficult to see how these two requirements will marry happily. On the same day that Mr Varley made his statement, the Secretary of State for Scotland, Mr Willie Ross, announced the results of the Drumbuie enquiry. This has ended in a victory for the National Trust and the villagers amongst others, since Mowlem/Taylor Woodrow's application to build Condeep concrete gravity platforms at Drumbuie, on one of the most beautiful parts of the north-west coast of Scotland, was turned down on environmental grounds after a lengthy public enquiry.

The result of the Drumbuie enquiry has both heartened and confused the environmentalists. Mr Ross said in his statement that he was not persuaded that the possible national gains depended solely on the Condeep design which Mowlem/Taylor Woodrow wished to build. This design can only be constructed at the very deep water sites in that area. The fact that the Drumbuie land is owned by the National Trust was also an important factor in the decision, since even if permission had been granted, parliamentary approval would have been needed. But Mr Ross also said that the official Reporter for the enquiry had examined five other sites nearby and had concluded that all were, or might be, suitable. There is already an application by Howard/Doris to build gravity platforms at Loch Kishorn further up the coast; this has been approved in principle by the local authority and objections are being con-

sidered by Mr Ross at the moment.

What confuses environmentalists is that development anywhere in the area will potentially be equally as destructive as at Drumbuie, since other sites under consideration (such as on the Crowlin Islands in the strait between Skye and the mainland) are even more remote from road and rail communications and are so near Drumbuie that the same social objections can also be made. Mr Ross has refused a public enquiry at Loch Kishorn on these very grounds—that the objections are so similar that they need not be debated publicly once again.

Mr Ross has also said that his criteria for choosing a suitable site are

- that it must have access to existing facilities
- that it can draw on an existing labour source
- that it can make use of existing infrastructure such as roads and services

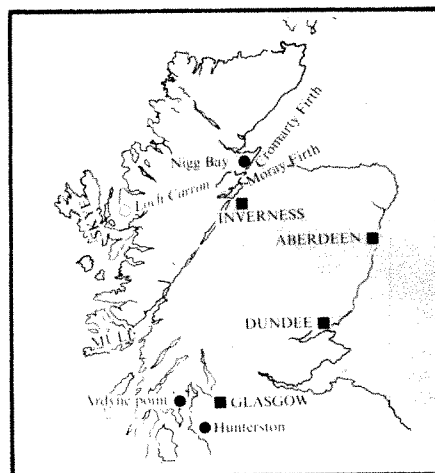

None of the Loch Carron area sites satisfies these criteria so the environmental groups opposing the Loch Kishorn application are hopeful.

But Mr Varley has put the Condeep platform design on his list of 'approved designs' for which he is willing to acquire sites. For his purposes, approved means most favoured by the oil companies. And the only place in Scotland that Condeep can be built is at one of the Loch Carron sites, which have exceptionally deep water close to a flat shore area.

For some time Condeep was thought to be the cheapest and best design for the deepwater oilfields but recent events have proved that this may not necessarily be so, and the image of Condeep as the saviour of the national economy is being challenged from several sides.

A spokesman for the Conservation Society said that as far as the Loch Carron area was concerned, Mr Varley's proposals were "irrelevant" because the society feels that the Condeep platforms are unnecessary. They point to the very successful French design which McAlpine is building at Ardyne Point on the Clyde near Glasgow. This Seatank platform can operate in 600 feet of water but unlike the Condeep does not need very deep water close to the building site, and can be towed some distance for final assembly.

Another blow to claims that the Condeep design is uniquely suitable for deepwater operations came when Shell ordered an Andoc concrete gravity platform for its deepest water site in the Dunlin field and Signal Oil chose a steel design for its Thistle field because seabed conditions proved unsuitable for gravity platforms. Diffi-

culties have also been experienced during the construction of Condeep platforms, at the time when the base is submerged. It was found that when submerged, one of the hollow base cells cracked under the water pressure and the design had to be modified so that the cells could be filled with concrete to overcome this.

Mr Varley's proposals could prove useful, however, in preserving the continuity of work at east coast sites. McDermott at Ardesier near Inverness has no more orders and the workforce faces redundancy as soon as present work is finished in a relatively short time. Mr Varley may find himself faced with the need to use his intended powers of restoration of the site and redeployment of the workforce sooner than he thinks. □

Infrared telescope for space shuttle

THE NASA Ames Research Center has awarded a \$400,000 contract to Hughes Aircraft Co. for a design study to be carried out for an infrared telescope which could be flown in the space shuttle. The contract specifies a pointing accuracy of 1', and is expected to have an aperture in the range 1 to 1.5 m, rather larger than the 36-inch instrument which is the main tool of NASA's existing flying observatory and is mounted in a C-141.

According to a report in *Aviation Week & Space Technology* (August 19), Michel Bader, deputy director of astronautics at Ames, describes the shuttle facility as "an extension of the C-141 programme"; but the new instrument will have cooled optics and detectors, as well as appropriate changes for zero-g operation and other problems specific to the shuttle.

Grumman Aerospace Corporation will be working with Hughes on some aspects of these problems, and the study will take at least a year. Work on the hardware may not begin until well into 1977. □

Sweden's reactor problems

from Wendy Barnaby, Stockholm

THE Swedes have not yet been notably successful in the efficiency of their nuclear technology. Current frustrations in the eight-reactor building programme now under way include altering the cooling systems of two reactors, replacing a fatigued metal part in another and putting up with delays in construction in a fourth. And there was, of course, the famous Marviken reactor, whose design was so faulty that it could never be made operational and was converted to work on oil. (Critics of this waste of money labelled the project "the first oil-fuelled nuclear reactor in the world"; a designation quickly adjusted, during the oil crisis, to "the world's first wood-fuelled-oil-fuelled nuclear reactor"). But now it seems that Sweden's nuclear power programme is running into difficulties of quite another sort.

Until the last couple of years, the large-scale development of nuclear energy in Sweden was accepted by the country without controversy. The consumption of electric power was predicted to increase three-fold by 1990, but expansion of hydro-power, which provides 70% of all Sweden's electricity, was regarded as a non-starter for environmental and economic reasons. Coupled with Sweden's poverty in coal, oil and natural gas, this problem put a high priority on the development of alternative energy sources. Nuclear power was the obvious choice. The government drew up plans to build 24 reactors by 1990. The country was to approach the next century as the world's leader in reactor capacity per capita.

All this had reckoned without the activities of an increasingly vocal anti-nuclear power group, whose agitation caused parliament in May 1973 to suspend approval of the official plan until it had been presented with more comprehensive information about reactor safety and radioactive waste. The parliamentary decision did not affect the reactor in operation since 1971 or those already under construction, but postponed consideration of the future of the other sixteen until next year. The advanced state of the programme has, in effect, solved the question of whether to have nuclear power. At issue now is how much Sweden should have in the light of current safety measures.

The fact that Sweden has not yet signed a safeguards agreement with the International Atomic Energy Agency under the Nuclear Non-proliferation Treaty, and the significance that could have in a large-scale peaceful nuclear

programme (especially after the explosion of India's bomb), has not been at issue. To begin with, the Swedes are expected to initial a safeguards agreement next month; but, more importantly, all the parties to the dispute agree that Sweden will not manufacture nuclear explosives.

The dispute has caused an odd political line-up. The ruling social democrats and the conservatives both favour the large-scale development of nuclear energy, while the agrarian and communist parties are against it. The anti lobby claims widespread public support, quoting as evidence a survey commissioned by the State Power Board and private producers of energy last January, at the height of the fuel crisis, to find out whether people favoured nuclear power or not. The results were not made available to the press. Not until a 'Friends of the Earth' group forced their publication in June could it be ascertained that 59% of the sample had in fact opposed nuclear power. In spite of this support, however, the anti group is worried about the plentiful funds being made avail-

able for pro-nuclear pamphlets and educational material which will be circulated to union study-groups this autumn.

Autumn will also bring publicity for the anti group, however. A number of citizens living near a new reactor site will appeal against the decision of a so-called 'Water Court' to allow the construction of the reactors planned for the site provided that certain measures are taken to safeguard the environment. Under a law outdated since these events began, such a court was obliged to review the potential dangers threatened by any proposed building to the water environment before permission could be given for the building to be constructed. The action will take place in the court of appeals dealing with questions involving water, and the argument will of necessity be limited to those aspects of nuclear power dependent on water. The public can therefore expect to hear a lot about dangers involved in a failure of the emergency cooling system and the pollution of waterways with radioactive material, but little about other nuclear hazards.

Inflation and Imperial College

by Roger Woodham

AT a time when many British universities, notably Leeds, are reporting that they are in the red by hundreds of thousands of pounds, the Imperial College of Science and Technology in London is still firmly in the black, thanks to some wise financial management a year or so ago.

In the year ended July 1973, for example, the college spent some £11.8 million but managed to salt away £635,000 to swell its reserves to £767,000. This was achieved by obliging all departments to reduce their budgets by 6%. The result was that earlier this year, with plenty of money in the bank, the college was able to embark on a modest expansion programme when many other universities were watching their margins closely.

The position now is that the reserves stand at about £250,000 and the college is faced, like other universities, with a government decision to be less than generous about supplementing the University Grant Committee's recurrent grant to allow for inflation. The government, assessed the situation several months ago on the basis of the rise in costs during the calendar year 1973, with a view to paying the extra

money during the academic year 1974-75. The first estimate of the increase in costs came out at 7%—some £13.5 million—and the government declined to give the universities any more money at all. But the increase in the index was subsequently revised upwards to 10%+, representing more than £21 million. At this stage the government announced that it would provide £4 million which, together with about £3 million which the UGC had at its disposal for emergencies, just kept the total deficit to the level the government originally envisaged.

Although the Committee of Vice Chancellors and Principals welcomed the government decision to make the extra money available, its view is that the recurrent grant should be restored to its proper level and its value then maintained in real terms.

What Imperial College is now waiting to find out is how much of the £4 million will come its way. On previous experience the amount will be in the region of £150,000 to £200,000, but Mr M. J. Davies, secretary of the college, said last week that the extra money would at best keep the ship afloat and would not allow for any growth. He also described the college's remaining surplus of around £200,000 as a cushion which is rapidly disappearing. If things get much worse, he said, Imperial College will be in the same situation as other universities.

Binary weapons voted out

by Colin Norman, Washington

THE Pentagon's plan to replace its ageing stockpiles of chemical weapons with a new generation of so-called binary nerve agents received a severe blow in the House of Representatives last week, and it now seems likely that Congress will eventually kill the plan entirely. Virtually unnoticed in the welter of events being played out in Washington, the House voted to deny funds for the Army to begin producing special 155-mm artillery shells for the binary weapons.

The vote, which came on an amendment to the Defense Appropriation Bill, represents sweet victory for a group of congressmen, led by Wayne Owens of Utah, who have fought the binary programme for months on the basis that if it were allowed to go ahead it would torpedo international chemical disarmament negotiations now taking place in Geneva.

The Pentagon—or, more accurately, the Army Chemical Corps—had requested \$5.8 million this year to begin producing binary shells in the Pine Bluff Arsenal in Arkansas, with a view to replacing part of its nerve gas stockpiles with binaries in 1977. The Army began touting the advantages of the weapon late last year, by arguing that since they consist of two "relatively non toxic" components, they will be safe to store, transport and use. The idea is that the two components would be kept apart until needed on the battlefield, then they would be loaded into the binary shell and mixed together to form a lethal nerve agent.

But the House was persuaded last week that if the United States now launches a massive new chemical weapons programme, the credibility of United States negotiators in Geneva would be destroyed and the chances of reaching agreement on international chemical disarmament would be negligible. Last month Mr Nixon and Mr Brezhnev signed an agreement in Moscow to launch new initiatives to help the negotiations along, but the binary weapons programme is scarcely seen as a helpful initiative.

Another factor in last week's vote was that the Pentagon had asked for funds from Congress before the binary programme had even been approved by the Administration, a situation which several congressmen regarded as putting the cart before the horse. In fact, since Congress started considering the funding request, the Administration has been carrying out a review of the necessity for binary weapons, and the programme has already picked up strong opposition from the Arms Con-

trol and Disarmament Agency. Thus, the Pentagon's strategy seemed to be to try to get approval for the programme from Congress and then use that to bolster its case with the Administration.

Last week's House vote was, however, far from the last word on the matter, for the Senate has yet to consider the Pentagon's budget request. But it is generally believed that the anti-binary forces in the Senate will be strong enough to uphold the House's action. For one thing, an amendment will be offered in the Senate Appropriations Committee to cut off funding of binary weapons, and if that fails a number of influential Senators led by Edward M. Kennedy are prepared to take their case to a vote on the Senate floor. □

Windfall for natural resources

THE Wolfson Foundation recently announced its £1 million programme of support for research into the more efficient use of natural resources. The object of the programme is to come up with at least some answer to the problems of Britain's dependence on imported food, raw materials and energy.

This is a departure from the foundation's previous practice of giving grants for university research linked specifically to industry. The foundation received more than 150 applications for money, and in choosing the 18 projects which make up the present programme it was particularly anxious that ideas should be quickly and easily realisable commercially if the research was successful.

The projects chosen cover a wide field. Predictably, studies on various sorts of recycling and uses of wastes are much in evidence, and on the energy front there are two concerned with the use of solar energy. But money has also been found for work on the impact of motorways on agricultural land, and on cultivating the scallop, a potentially valuable export.

The Department of Agriculture at the University of Reading gets the largest slice of the cake. It has been given £250,000 for two pieces of work: one to improve the production and direct use of green leaf protein, and one for improving the production of oil and protein from seed crops. Together with a complementary study at the University College of Wales, Aberystwyth, on breeding grasses and legumes for upland areas, these lines of research could eventually lead to far more home-grown feedstuffs for Britain's animal and even human population. □

Ecological railway line

from Vera Rich

THE new branch of the Trans-Siberian Railway, which is to run via Ust-Kut on the Lena, skirting the north of Lake Baikal, and across some 1,500 km of the Siberian taiga to join the existing tracks at Komsomolsk on the Amur, is clearly being treated as a prestige project by the Soviet media, which faithfully report every step in its progress.

This publicity is, perhaps, not surprising, since the projected line will run through some of the most promising of the undeveloped areas of Siberia. The line will, however, pass through a region which is a constant focus of attention for ecologists.

Lake Baikal has, of course, been subject to railway 'pollution' since the trans-Siberian route was envisaged in 1891. Indeed, in the early days, the track actually ran across the lake—rails were laid on the ice in winter and ferry boats were used during the summer (with a twice-yearly break in service during the thaw and freeze-up).

Conservation has now become an emotive concept, and the planners of the new line have not only taken it into account in their proposals for the line, but have also taken considerable care to be seen to be taking it into account.

Mikhail Reks, the chief engineer of the Baikal project, has assured world opinion (through the Novosti agency) of the environmental protection measures to be taken. No tree felling is to be permitted on slopes with gradients exceeding 15°, or in valley bottoms, to obviate erosion caused by avalanches and mud streams. Special dams and trenches in permafrost areas will protect the soil—as well as ensuring the safety of the railway itself. The banks of the reservoir on the River Zeya are to be reinforced, and it is stated that the massive bridge-building programme involved (over 140 bridges in all) will tend to stabilise the channels of the Siberian river beds, and thus reduce erosion.

The wild life of Siberia is to be left as undisturbed as possible—although Reks admitted that the line will to a certain extent "press back" many species. One wonders however, how the construction workers themselves will react to the ruling on insect life. For, in order to disturb the ecological balance as little as possible, no insecticides may be used, not even against the traditional curse of Siberian life—mosquitoes. The only means of self defence permitted, according to the official ruling, will be mosquito nets and special repellent creams. □

correspondence

Chile: for . . .

SIR,—I have recently read your editorial of May 3, on academic freedom in Chile, and would like to make some comments on it.

This is the third occasion I have come to Chile to lecture, the previous visits being in 1970 (before Allende's election) and 1971 (under the UP government). I also lectured here in 1965 (shortly after Frei's election) but not with a contract. I cannot claim to know the state of all the branches (*sedes*) and faculties of the University of Chile or other universities, but I am tolerably well acquainted with what goes on here. I can assure you that as far as this department is concerned, your article is almost totally untrue.

I have seen no military in or near the Faculty in my two months here, although I do understand that they searched it for arms a couple of days after the coup, since when they have not returned. Not one member of staff of this department has been dismissed for political or any other reasons.

Actions 'such as not taking part in the anti-Allende demonstrations' are not 'now retrospectively considered illegal'. Hardly anyone in the department ever took part in such actions. On the contrary a considerable number of the staff and perhaps 50% of the students regularly took part in pro-Allende meetings or demonstrations. To all those UP sympathisers or militants (not to mention the apolitical) who stay unchanged in their academic posts, your suggestion that they 'remain at the universities in puppet roles' is insulting. You conclude the phrase by adding 'organising research according to the junta's decree, teaching what the junta thinks fit to be taught'. The courses here are submitted to no one, military or otherwise, for approval. My own course has not been reviewed even by the director of the department.

Your report must certainly be true for some academic institutions (because I cannot believe the entire international press is misinformed) but it is nowhere near the whole truth. Either you too easily believe the statements made in Europe by refugees, genuine or otherwise, without attempting to verify them, or you are not concerned with straight reporting and are motivated by political considerations. If the latter is true and *Nature* has ceased to be a scientific journal to become a political one, may I, as an Irishman,

suggest you focus your concern about military misbehaviour on your own army for which you are indirectly, and many British scientists directly responsible, rather than on the army of a country on the other side of the globe where you apparently have never set foot.

I am no apologist for the military junta; on the contrary I am a strong supporter of the ideals of social justice which Allende claimed to support. However honesty forces me to admit that the most charitable interpretation of the cause of his regime's collapse was its catastrophic incompetence. The chaos that reigned in 1973 would have provoked a coup in any other Latin American country, and most European ones too. That said, and recognising the impertinence of making comments on the internal affairs of a foreign country, I unreservedly condemn the brutalities, vengeful actions and plain stupidities attributed to the authorities at various levels since September 11. Perhaps, following the above, I can best demonstrate my conviction that academic freedom and 'intellectual life' in Chile is *not* 'dead' by signing myself openly

Yours faithfully,

W. F. L. PURSER

*Universidad de Chile,
Santiago de Chile*

. . . and against

SIR,—The Chilean replies to the letters published in *Nature*, criticising the regime, although insulting the intelligence of your readers, underline the spirit of a totalitarian regime, a trivial phenomenon these days. However, there is no necessity to refute arguments which only underline how ideological fanaticism can deform judgement.

It seems more important to stress the need for the scientific community, which is rightly reluctant to become involved in political controversy, to assert that it cannot remain indifferent when individual freedom is at stake under any politico-economical order, religious or social prejudice. It is a matter of dignity for scientists to know that the torturers' representatives be at least excluded from their community, if more drastic action cannot be taken.

As for those, whether nationals or 'multinationals', who support regimes of the Chilean or Czechoslovakian type, they would be well advised to have the decency to spare us the nausea of their

public apologetic justifications. They might also be advised to consider that Portugal and Greece are perhaps not just mere accidents.

Yours faithfully,

DIMITRI VIZA

*Laboratoire d'Immunobiologie,
Faculté de Médecine Pitié-Salpêtrière,
Paris*

Publish or perish

SIR,—How can we escape from the tyranny of the Science Citation Index (how many citations did your papers get last year?) and the general publish-or-perish rat-race?

I suggest a procedure by which a stable and well-established department might contract out. Let all papers from the department be published under the same fictitious name, as is done by the pioneer French school of mathematicians who are Nicholas Bourbaki — a general who, when defeated, tried to shoot himself but missed. What effects might follow?

We might build one substantial scientist out of several mediocre ones, whose success might encourage the others. As Blackett has pointed out: "a first-class laboratory is one in which mediocre people can do outstanding work".

The Matthew Principle (Matthew, 25: 29) of R. K. Merton, "to every one that hath shall be given . . ." will be turned to general advantage since $(A + B + C + \dots)^x > A^x + B^x + C^x \dots$ (if $x > 1$).

The general standard of papers might be increased and their numbers reduced by taking off some of the pressure on the individual to rush into print.

Multiple subscriptions to journals and societies could be reduced.

The promotion scheme based on published papers would be confounded, perhaps forcing the consideration of persons as persons.

There has been much talk of the commonwealth of science, but who will be the second to set up a scientific commune? I am sure that common scientific property will be as strongly opposed by the establishment as the commonality of the property of Christians was opposed by the Church of England (Article 38).

Yours faithfully,

ALAN MACKAY

news and views

Transfer RNA revisited

It is now some six years since the first successful crystallisation of transfer RNA was reported by a group of workers at the MRC Laboratory of Molecular Biology, Cambridge (*Nature*, **219**, 1222; 1968). Subsequently a large number of both mixed and purified tRNA crystals have also been obtained. There has, however, been a central problem in obtaining crystals of sufficient quality. Only this would enable an X-ray structural analysis to provide a detailed picture of the molecular architecture of tRNA. In 1971, Kim, Rich and their associates, at the Massachusetts Institute of Technology, reported that they had obtained highly diffracting crystals of the tRNA from yeast which codes for phenylalanine (*Proc. natn. Acad. Sci. U.S.A.*, **68**, 841; 1971). These workers then proceeded to analyse these crystals, and reported obtaining electron density maps at successively 5.5 Å and 4.0 Å resolution, culminating in a 3.0 Å map using the standard isomorphous replacement methods of protein crystallography (*Nature*, **248**, 20; 1974). Each improvement in resolution enabled the form of the molecule to be visualised more clearly, and their final electron density map showed the molecule to have an L shape, with two stems of double helical oligonucleotides in each arm. The polynucleotide chain was clearly seen, except in the nonhelical loop regions of the molecule.

The tRNA species that the MIT group has been investigating crystallises in many (up to twelve) distinct crystal forms. This intense polymorphism raises the question whether it is a reflection of merely alternative packing modes within the crystal lattice, or a consequence of conformational changes within the tRNA molecule. Cramer *et al.*, in a thorough examination of crystallising conditions for eight of these polymorphs, have remained undecided on this question (*Biochim. biophys. Acta*, **349**, 351; 1974). The MIT group has attempted an answer by extending its original analysis, on an orthorhombic form, to the monoclinic form. Both of these polymorphs diffract X rays well, to a resolution of better than 3 Å. So it is reasonable to suppose that the molecules in both forms are packed reasonably well. Furthermore, the two forms are related in terms of unit cell dimensions, suggesting closely related structures. Kim *et al.* used simple molecular replacement procedures in order to see how their orthorhombic molecule fitted the data from the monoclinic crystals. They obtained reasonably good fits and concluded that the structure was essentially unchanged on going from one form to another. The only proviso was that there were possibly some small undefined changes in the region of the anticodon loop.

The Cambridge (England) group has now reported their independent 3 Å analysis of the monoclinic form (Robertus *et al.*, *Nature*, **250**, 546; 1974). Again, the method of isomorphous replacement has been used to solve the structure. The outline shape of the molecule was obtained by tracing the ribose phosphate backbone, particularly in the four stem regions where it was most discernible. Clearly, compared with a polypeptide backbone in a protein, polynucleotide chains are considerably more difficult to follow. This is mainly because of the close similarity of ribose, phosphate, purine and pyrimidine groupings when seen at a resolution of 3 Å. It did not prove possible to trace unambiguously and

completely the chain in the non double-helical D and T ψ C loops; the MIT group has similar difficulties in these regions of the molecule. The monoclinic form is very similar in overall shape to the Cambridge (Massachusetts) orthorhombic findings. The fact that the former shape has been called a T, and the latter an L, is to some extent a matter of semantics. There are, however, a large number of significant differences between the two structures. Perhaps the most important concerns the orientation of one of the double-helical stems, the so-called D stem, which differs in the two by 90° in one direction. It is noteworthy that the main helix directions now all agree well with Levitt's helix search locations (*J. molec. Biol.*, **80**, 225; 1973). The relative placing of the other three stems is not disputed. There is a disagreement about the fitting of the nucleotide sequence to the chain, by one (and sometimes two) residues, virtually throughout the entire molecule. Robertus *et al.* consider that these shifts in the chain assignments have necessitated revision of many of the earlier structure conclusions. For example, whereas the helical stems were previously considered to be irregular, they are now found to conform to the standard classes: the amino acid and the T ψ C stems together form a twelve base-pair-long double helix of the 'A' form. The functionally important anticodon loop seems to have more order than previously described with stacking on the 3' side of its stem. This, together with the quasihelical geometry of the anticodon bases, is one of the many satisfying features of the new model. The Cambridge (England) group detail the features of the molecule which help to maintain its structure. These are additional base pairings, and also base triplets—many of a novel nature—as well as numerous stacking and intercalative interactions.

These tertiary interactions cumulatively have the effect of folding and maintaining the familiar tRNA cloverleaf into a molecule with essentially three major interlinked substructures. These are, firstly, the long, almost perfect double helix formed by stacking the acceptor and T ψ C stems. The D stem is augmented by several unusual base pairs and postulated triplets, some involving their own loops, and some the variable loop, and is attached to the long helical segment almost at the middle. This forms the T junction. The anticodon stem then extends outwards from the augmented D helix, with the helices separate and non-collinear. Indeed, the anticodon helix (with its loop at the far end of the molecule) seems almost to be hinged on to the D stem, with a consequent implication of mobility, possibly during protein synthesis.

This new model has also been examined for consistency with the extensive chemical modification data which now exist for tRNAs (Robertus *et al.*, *Nucleic Acids Res.*, **1**, 927; 1974). It has now been assumed that bases susceptible to modification are those not involved in tertiary interactions. On this basis, double-helical residues would be unaffected, as indeed they are. Similarly, those bases involved in the tertiary interactions detailed in the X-ray model would not be modified, as indeed they are not. The reactive bases are the ones that are not only uninvolved in tertiary interactions but are on the surface of the molecule. The model is also of interest in that it suggests that many of its structural features are common to all tRNAs. The bases which are either invariants in all tRNAs, or are conserved as purines or pyrimidines, are mostly involved in the tertiary interactions. Thus, the pattern of

molecular folding, so dependent on these, may well be at least similar for the majority of tRNAs.

The Kim and Rich group have very recently made an additional contribution to the subject of tRNA structure (*Science*, **185**, 435; 1974). In what may be seen as a counter to the criticisms of their structural model, they have presented a comprehensive analysis of its tertiary structure. This necessitated revision of a number of the residue assignments, although the overall chain tracing remains generally unaltered. The tertiary base-pairing and stacking interactions now found are mostly identical to those in the Cambridge (England) model, although a number of differences in interpretation still remain. In general the two models are now very similar. Consequently, it is now possible to state, with some considerable measure of confidence, that the basic structure of a transfer RNA has been established.

STEPHEN NEIDLE

Molecular neuroanatomy

NEUROANATOMY has relied for many years on a limited number of classical staining methods, the chemical bases of which have remained largely obscure. During the past few years, however, the field has seen a quiet revolution as several powerful new techniques have developed as a result of a greatly increased understanding of the special biochemical properties of nerve cells. Many of these new methods make use of the fact that neurones of different types are biochemically differentiated in the sense that each type manufactures and stores only one of a series of potential transmitter substances. Great progress has stemmed, for example, from the development of a histochemical fluorescence technique for visualising catecholamine and indolamine-containing neurones and their fibres (Falck, *Acta physiol. scand. (second suppl.)*, **197**; 1962).

Such specific staining methods have so far not been available for neurones using other transmitters. One approach of general applicability is the development of immunofluorescent histochemical techniques, using antibodies directed against some protein that is characteristically localised in a given transmitter-specific type of neurone. Thus, antibodies to the enzyme dopamine- β -hydroxylase have been used to identify noradrenaline-containing neurones in tissue sections (Fuxe *et al.*, *Progr. Brain Res.*, **34**, 127-128; 1971). Progress in the application of such methods to other transmitter types has been reported recently. Saito *et al.* (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 269-273; 1974) describe the use of antibodies to the enzyme glutamic decarboxylase for the immunofluorescent identification of neurones that use gamma-aminobutyrate (GABA) as their transmitter and Eng *et al.* (*Nature*, **250**, 245-247; 1974), McGeer *et al.* (*J. Pharm.*, **5**, Suppl. 1, 54; 1974) and Rosser *et al.* (*FEBS Lett.*, **36**, 43-48; 1973) have prepared antibodies to purified choline acetyltransferase and described their use for the identification and mapping of cholinergic neurones in the central nervous system (CNS). These neurones have hitherto been identifiable only by histochemical methods for the enzyme acetylcholinesterase; the localisation of the biosynthetic enzyme choline acetyltransferase, however, promises to be a more specific and reliable biochemical marker for such structures, since this enzyme occurs exclusively in cholinergic neurones in the CNS.

These new methods for identifying transmitter-specific neuronal pathways have been and will continue to be of immense value for mapping the distribution of such pathways in the CNS. At the same time two other approaches,

which represent more general means of determining the axonal projection of groups of neurones in the CNS, have been developed. Both approaches make use of the specialised transport systems that exist for the movement of substances along nerve axons. Protein synthesis in neurones is confined largely to the cell body region of the cell, and there is continuous export of newly synthesised material from the cell body along the axon processes to the nerve terminals. This orthograde flow of material can be used to trace the axonal projections of neurones by pulse-labelling the cell bodies with a radioactively-labelled amino acid and then following the transport of labelled protein into such projections. This usually involves a local microinjection of isotope in the region of a particular brain nucleus, followed by autoradiographic examination of the distribution of label in various potential areas remote from the site of injection (Cowan *et al.*, *Brain Res.*, **37**, 21-51; 1972). Another more recently recognised transport mechanism operates by as yet unknown means to transport certain proteins from the nerve terminals in the retrograde direction towards the cell body regions of neurones. By using an easily identified marker protein not normally present in the CNS, such as horseradish peroxidase, it is thus possible to determine the cells of origin of fibre tracts in CNS. This substance is applied by local injection into a projection area, and then peroxidase-containing cell bodies are identified in remote brain areas. (La Vail *et al.*, *Brain Res.*, **58**, 470-477; 1973).

Apart from methods that allow the mapping of populations of neurones organised in specific pathways, important developments in techniques that reveal the detailed anatomical features of individual neurones have also been made. Stretton and Kravitz (*Science*, **162**, 132-134; 1968) found that microinjection of the fluorescent dye procion yellow into single neurones of the lobster nervous system allowed the subsequent visualisation of even the finest branches of the axonal and dendritic tree emanating from such neurones. Procion yellow diffuses readily into such processes, and the neurone remains electrically excitable during the process. This technique has been widely applied to invertebrate and vertebrate neurones, with results of often breathtaking clarity (*Intercellular Staining Techniques in Neurobiology*, edit. by Kater and Nicholson, Springer-Verlag, Berlin, 1973).

Autoradiography has also been used to trace the dendritic ramifications of spinal cord motoneurones following intracellular injection of radioactively labelled amino acids (Globus *et al.*, *Brain Res.*, **11**, 440-445; 1968). In last week's edition of *Nature* (**250**, 655-658; 1974) Pentreath and Cottrell described a further modification of this approach which depends on the injection of radioactively-labelled transmitter or transmitter precursor into single cells. This has the advantage that the transport of transmitter molecules along axons occurs more rapidly than that of labelled proteins and a higher proportion of the injected material may be transported over quite long distances in this manner. Pentreath and Cottrell worked with a large neurone in the cerebral ganglion of the snail *Helix pomatia*. There is one such giant neurone on each side of the ganglion, and the cells are known from previous neurophysiological and biochemical studies by the authors to use 5-hydroxytryptamine as their transmitter. After the microinjection of tritiated 5-HT or the precursor 5-hydroxytryptophan, using electrophoretic expulsion from the tip of a fine glass electrode inserted into the cell body, the labelled amine was rapidly transported away from the cell body into the axonal system. Within 10-15 h after injection label had penetrated into the fine terminals of the neurones, some of which were several centimetres from the site of injection. Using autoradiographic analysis of serial tissue sections the entire axonal projection could be mapped. The projection from each giant neurone was found to be complex, consisting of several large axonal processes and numerous smaller

branches. Some axons projected to the buccal ganglion, in which 'follower' cells have previously been identified in neurophysiological studies, others crossed the midline, and several terminated in various muscles concerned with feeding behaviour in the mollusc.

In addition to light microscope autoradiography, Pentreath and Cottrell were also able to use electron microscopic autoradiography to investigate the fine structure of some of the labelled terminals. All of the injected label appeared to be confined to the injected neurones, and this method thus offers a relatively rapid and highly specific means of

determining the various presynaptic terminals emanating from an identified single neurone.

It is clear that neuroanatomy has felt some of the impact of the molecular biology era, and that the battery of new techniques that have recently become available will stimulate an upsurge of activity in this area. Such a revival will come none too soon if one is to begin to understand the functional significance of the various chemically specific pathways of neurones that are now known to exist in the CNS.

L. L. IVERSEN

Clock and calendar in SI units

IN the SI system, one gives the time of day and date in kiloseconds, megaseconds and gigaseconds. The appropriate daytime clock has no minute hand and has a new face graduated 25–65 ks (see figure); if the range 0–86.4 ks was completed, the clock would also be suitable for night use. One's schedule might be: 25 ks, breakfast; 30 ks, start work; 45 ks, lunch; 60 ks, stop work; 65 ks, supper; 80 ks, retire.

On the calendar (see Table), one dates by the megasecond, stating a number under 100 with one decimal place. This increases daily except Sunday by 0.1 Ms. Thus, the eight days July 3–10, 1974, are 77.6, 77.7, 77.8, 77.9, 77.9+, 78.0, 78.1, 78.2 Ms. A + distinguishes Sunday. 0.1 Ms, however, must also be added on six Sundays out of 125 (since 1 week = 0.6 Ms = 4.8 ks). The megasecond date then never differs from the actual time each day begins by more than 90.4 ks. After making a correction for this difference, one adds the time of day (see figure) to fix any instant absolutely.

This continuous calendar does not begin anew each year. Subtracting the megasecond at the new year from the current megasecond gives the time of year, useful in astronomy, weather, biology and farming. To place a date in history, one states the gigasecond to the nearest 0.1; for 1972–74 this is 62.2 Gs.

The many advantages include elimination of timers graduated in diverse units, and of unsystematic derivatives such as revolution per minute and kilowatt hour. Moreover, 62 278.2756 Ms has fewer symbols and easier arithmetic than 11:40 a.m. July 10, 1974. Neither change in work schedules nor internationally agreed reform are needed; scientists and engineers can begin to use a SI clock and calendar today.

CHARLES E. CHAFFEY

Partial SI calendar								Date 1974
	Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	
Ms	77.3+	77.4	77.5	77.6	77.7	77.8	77.9	July 6
ks	69.6	56.0	42.4	28.8	15.2	1.6	-12.0	
Ms	77.9+	78.0	78.1	78.2	78.3	78.4	78.5	July 13
ks	74.4	60.8	47.2	33.6	20.0	6.4	-7.2	
Ms	78.5+	78.6	78.7	78.8	78.9	79.0	79.1	July 20

ks	-6.4	-20.0	-33.6	-47.2	-60.8	-74.4	-88.0	

Add 62.2 Gs. New Year was 61.8 Ms. The beginning of each day is the sum of the large figure (in Ms) and the small figure (in ks).

Primitive but not simple

THE study of human embryonic haemoglobin, initiated principally by Huehns and his collaborators, starts from the demonstration that biosynthesis of a 'primitive' or ε polypeptide chain precedes that of the γ chains of human foetal haemoglobin (Hb-F, $\alpha_2\gamma_2$). At birth Hb-F normally comprises some 80% of the total haemoglobin, the remainder being adult haemoglobin (Hb-A, $\alpha_2\beta_2$), as the biosynthesis of β chains is switched on, and that of γ chains starts to decline at 6 months' gestation. The ε chain occurs as Hb-Gower 1 (ε_1) and Hb-Gower 2 (ε_2) and its formation has completely stopped at a gestational age of less than 3 months. There is also evidence that synthesis of the α chain is preceded very early in gestation by another type of chain, originally denoted as x but now designated ξ . This chain is found in the haemoglobin species Hb-Portland 1 with composition $\xi_2\gamma_2$, believed to be present in early human embryos, and also found in stillborn infants

with erythroblastosis foetalis caused by homozygous α -thalassaemia 1, where α -chain synthesis is completely inhibited.

The practical problems associated with the study of human embryonic haemoglobins can be circumvented in animal studies, and Melderis, Steinheider and Ostertag, of the Max-Planck Institute for Experimental Medicine, Göttingen, now report (see page 774 of this issue) evidence for a unique x-type globin chain in early mammalian embryos (BALB/c mice and New Zealand white rabbits). The x chains of these two species have closely related sequences, similar to that of the human ξ chain of Hb-Portland 1. Detailed analysis of the complex systems—three embryonic species in the mouse and six in the rabbit—leads to the conclusion that there are at least two different ε chains, and that x- and α -chain synthesis in both species is inversely correlated, hence the first chain takes the place of the second during early embryo-

genesis. The x chain is now to be regarded as a α -type chain, and there is more sequence similarity between x chains of different species, than between the x and α chains of the same species. This indicates an early evolutionary divergence of x- and α -chain genes and constitutes a further example of globin gene duplication during evolution; compare the findings of Schroeder, Huisman and colleagues on the duplicated $^6\gamma$ and $^A\gamma$ genes for the γ -chain of human Hb-F.

The Göttingen work confirms the indication from the earlier work on human embryonic haemoglobins that there is an α -type x (or ξ) chain synthesised in the nucleated erythroid cells derived from the yolk sac during early stages of mammalian embryogenesis, and preceding the synthesis of α -chains proper. The presence of an ε_1 species in human but not in mice or rabbit embryos remains to be explained.

From a Correspondent

Topology of crystal grains

from Robert W. Cahn

It is one of the paradoxes of the history of science that the rigorous quantitative treatment of the behaviour of large populations of molecules preceded by many years the similarly rigorous description of the individual molecules themselves; yet the kinetic theory of gases implies the extraction of orderly and predictable behaviour from myriads of random motions and collisions, whereas molecules are all identical. The resolution of the paradox lies in the fact that in the kinetic theory, molecules are treated virtually as independent, featureless particles, and therein lies the tractability of the whole approach. A million particles spell simplicity; one molecule spells complexity.

With crystals, the sequence is reversed. A large number of crystal structures had been accurately determined before the collective behaviour of populations of crystals began to be understood. The metallurgist recognises two distinct forms of such collective behaviour: first, there is 'Ostwald ripening', a poetically metaphorical term for the Matthew principle applied to a population of spherical crystallites of varying radii dispersed in a matrix; the larger ones grow at the expense of the smaller, essentially because of a radius-

dependence of the solubility of the particles in the matrix. (Water droplets in a cloud behave in an essentially similar way.) The rigorous treatment of this very important metallurgical process is now well understood.

The second form of collective behaviour is grain growth. A piece of a pure metal consists of a population of crystal grains all sharing the same crystal structure but of different sizes, shapes and orientations. The grains grow from independent nuclei and as they impinge, grain boundaries are formed. The interfaces may be plane or curved, and bear no relation to the regular lattice arrangement of atoms: "There's no art to read the grain's construction in the face". Here, also, the Matthew principle operates: if a piece of metal is heated, the larger grains grow at the expense of the smaller through the migration of grain boundaries, and the average grain size progressively increases.

Grain growth has been studied micrographically for many years, both for its intrinsic interest and because of its practical influence on metal working, on the behaviour of nuclear fuel elements, in powder metallurgy and elsewhere. It has long been recognised that the mean grain diameter varies with time according to $\Delta D = kr^n$, where n falls in the range $1/3$ – $1/2$. The problem is to understand why. It is a conceptually more difficult problem than the kinetic theory of gases, because

crystal grains are not independent and separate particles, but connected polyhedra. When one grain changes shape and size, the neighbours of necessity change too. An assembly of grains is like a nuclear reactor: a change in neutron absorption in one small corner soon leads to a change in neutron flux throughout the reactor. Similarly, an instability at one corner of one grain quickly spreads through the population.

The key to an understanding of the problem is its topology. A population of polyhedral grains can be characterised by the number of grains, faces and vertices, and by the relations between these quantities. In particular, interest attaches to the mean number of faces per grain and the distribution of this number among the grain population. Topological principles were first applied, to assess the stability of a grain population, by C. S. Smith in 1952. He recognised that grain growth stems from disequilibrium at edges where three grains meet and at four-grain corners. Unless three boundaries meeting at an edge are mutually inclined at 120° the edge must move and the boundaries become curved. The curvature itself introduces instability; indeed, curvature and non-equilibrium edge and corner configurations are the fuels of grain growth. The nearest approach to equilibrium obtains in a population of fourteen-sided polyhedra of a particular shape.

In a brilliant paper Rhines, Craig and

Dehoff (*Metall. Trans.*, **5**, 413; 1974) apply topological analysis to grain growth in a highly illuminating way. Their article is based upon an experimental study of successive stages of grain growth in aluminium, using the technique of serial sectioning; the technique depends on a thorough mastery of the theory of quantitative metallography which allows two-dimensional measurements in the microscope to be converted into reliable three-dimensional geometrical statistics. In their laboratory at the University of Florida, the authors have honed this technique to a fine cutting edge. They are able to determine the total grain boundary area, mean boundary curvature, distribution of the number of faces per grain, as well as the true mean volume per grain, as a function of time.

By combining experiment with topological analysis, Rhines *et al.* are able to introduce the concept of a "structural gradient" which is essentially a measure of the mean deviation from equilibrium of the entire grain structure. It is equal to the product of the total mean curvature and the surface area per grain. This structural gradient determines the rate of steady-state grain growth, and remains unchanged because the form of the distribution of different grain shapes remains unaltered as grain growth proceeds. All this is made topologically clear by the authors. They also show in a simple and elegant fashion that the number of grains eliminated when a grain boundary sweeps through unit volume of material is a constant, independent of the mean grain size. This very important theoretical result will have a number of important applications in materials science (for instance, in connection with sintering of powders, in which grain growth plays a crucial part).

By putting the various parts of the analysis together, the authors find both theoretically and experimentally that grain growths follow the law $\Delta D = kt^{1/3}$, when the 'diameter' D is expressed as the cube root of the mean grain volume. The apparent grain diameter derived from intercept analysis on a single two-dimensional section gives an index rather higher than $1/3$, which indicates that good quantitative metallography requires more expertise than most investigators possess. The authors point out that "it has not been required, in developing the foregoing rate law, to introduce any arbitrarily adjustable parameter, as has been done in the usual expression of grain growth kinetics". Theirs is an impressive achievement.

A recent attempt to apply purely statistical principles to grain growth (Louat, *Acta Metall.*, **22**, 721; 1974) is an instance of the type of analysis at which the Florida authors, by implica-

tion, cock a sceptical eyebrow. This is not to say that the statistical approach has no value: for instance, Weaire (*Metallography*, **7**, 157; 1974) shows how statistical arguments can be combined with topological ones to assess whether a distribution of grain shapes deviates locally from randomness.

Another recent article of striking originality on a related theme is by Morrall and Ashby (*Acta Metall.*, **22**, 567; 1974) who consider an assembly of fourteen-sided polyhedra in near equilibrium, as per Smith's specification, and then introduce a number of thirteen or fifteen-sided grains, or other more serious 'grain defects'. The grain structure is then denoted by joining the centres of all neighbouring grains, through their common boundaries, by a network of lines. These lines form a lattice ('lattice graph') with dislocations wherever there is a grain defect. These dislocations can move conservatively (using the term in the special sense of dislocation theory); this corresponds to grain displacement of the type found in superplasticity, without change in the number of grains. Dislocations can also move by climb, which implies the disappearance of some grains in 'real space' and therefore corresponds to grain growth. The authors build on an earlier analysis by Hillert of grain growth in two dimensions, where a set of perfect hexagons is disturbed by some rogue pentagons, and the like. For three dimensions, they relate, as did Hillert for two dimensions, the rate of grain growth to defect density, that is, to the density of dislocations in the lattice graph. They predict that if the defect density is constant, $\Delta D = kt^{1/2}$, while the index $< \frac{1}{2}$ if the defect density decreases during grain growth.

Morrall and Ashby's analysis represents an interesting link between the purely topological and purely statistical approaches. Since the Florida authors showed experimentally that the grain shape distribution is invariant with time (that is, the grain defect population is invariant too) Morrall and Ashby's analysis predicts $\Delta D = kt^{1/2}$, which is inconsistent with the experimental findings of the Florida group. The problem of grain growth has plenty of mileage left for those investigators who can master the requisite degree of subtlety.

Spartina's success in salt marshes . . .

from Peter D. Moore

THE grass genus *Spartina* is a remarkable one, both in terms of its worldwide success as an intertidal, salt-marsh species, and because of its very high production rates in such situations.

In the British Isles the spread of *Spartina anglica* (= *S. townsendii*), particularly during the early part of this century, is well known. The success of this species may be attributed to its remarkable capacity for strong growth over a wide range of levels in the salt marsh as well as to its salinity tolerance. Once established it forms dense clumps, which Ranwell has estimated may expand at a rate of 2% per annum on an area basis (*J. Ecol.*, **52**, 95; 1964). It is thus a powerful competitor, often forming dense, single species stands over wide areas.

On the east coast of North America there are several species of *Spartina* which show a tendency towards localisation within specific zones of the salt marsh. For one of these species, *S. alterniflora*, there are now a number of estimates for annual shoot production. Production rates, as indicated by above ground standing crop at the end of the growing season, are greatest in the southern States: for example, Teal (*Ecology*, **43**, 614; 1962) found standing crops of 1,290 g m⁻² dry weight in Georgia, whereas in Rhode Island Nixon and Oviatt (*Ecol. Monogr.*, **43**, 463; 1973) found 840 g m⁻². These figures are fairly representative of the falling production of the species as one moves north (see the literature review by Keefe, *Mar. Sci.* **16**, 163; 1972).

More detailed studies of the seasonal changes in productivity and the chemical composition of *S. alterniflora* in a New Jersey salt marsh have been carried out by Squiers and Good (*Chesapeake Sci.*, **15**, 63; 1974). Production in early spring was 8 g m⁻² d⁻¹ rising to 26 g m⁻² d⁻¹ in early summer. The peak standing crop was 1,592 g m⁻², but in late summer this trend was reversed and there was a net loss of dry matter at a rate of 13 g m⁻² d⁻¹. This loss could be caused by enhanced respiration rates relative to photosynthesis or, more likely, the death and loss of lower leaves. Since *Spartina* is not heavily predated by herbivores, the fall of litter represents the most important channel whereby the energy fixed in photosynthesis is passed on to heterotrophic organisms.

There is also a build up of protein, reaching maximum levels in the early spring. Presumably the plant has a strong demand for soil nitrogen at this period since this nutrient could become limiting to growth later in the season. Indeed, Sullivan and Daiber (*ibid.*, **15**, 121; 1974) have found that production rates in the dwarf form of *S. alterniflora* are limited by nitrogen supply in the growing season.

These data confirm the assertions of Odum that the salt marshes of the eastern United States are among the most productive habitats in the world. They also point to *Spartina* as a key

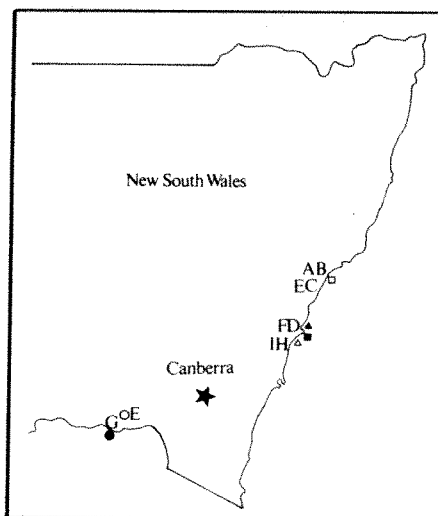

species in this high productivity. Recent studies on the physiology of *S. anglica* in Britain have suggested that this is one of the few temperate grasses which has adopted the C_4 system of carbon assimilation (see *Nature new Biol.*, **246**, 98; 1973), a mechanism frequently associated with high productivity. It is likely that this propensity for CO_2 fixation by the C_4 pathway is shared by other members of the grass *Spartina* which could account, in part, for its success in temperate salt marshes.

... and alligator weed spreads in Australia

from John Hockley

ALLIGATOR weed (*Alternanthera philoxeroides*), a normally harmless aquatic weed, is spreading rapidly in the rivers and canals of eastern Australia; it is blocking irrigation channels and is threatening the fishing, prawning and oyster industries along the Georges River near Sydney in New South Wales. The natural home of this species of weed, which belongs to the family Amaranthaceae (Duke, *Ann. Mo. bot. Gdn.*, **48**, 43; 1961), is South America and it was first noticed in Australia in the mid-1940s when it was seen growing on heaps of ballast dumped ashore at Carrington near Newcastle (see map). It seems to be spreading rapidly because although its seeds are infertile in Australia, it can reproduce vegetatively, its natural insect enemies are absent and it is able to flourish in a variety of habitats—it does particularly well in rivers enriched with sewage effluent.

The weed has been reported from places as far apart as Grafton, on the north coast of New South Wales; Williamstown, north of Newcastle, where it is blocking drainage canals; and Albury on the Victorian border, where it is not only a menace along irrigation canals, but also a possible threat to the Murray and Murrumbidgee Irrigation Areas. The largest

Recorded occurrences of alligator weed in New South Wales. 1946(A), 1962(B), 1965(C), 1969(D), 1970(E), 1971(F), 1972(G), 1973(H), 1974(I). □, Newcastle District (Williamstown, Carrington and Maitland); ▲, Carnarvon Golf Club (Lidcombe); ■, Duck Creek (Clyde); △, Georges River (Casula, Glenfield and Liverpool); ○, Holbrook; ●, Lake at Woomargama (Albury).

infestation is along the Georges River on Sydney's south-western boundary, where the optimum environment, one containing a high level of nitrogen, is provided by the effluent from the many sewage treatment works that empty into the river. In addition to the threat to the fishing industries, recreational activities such as swimming, water skiing and rowing along the river are being affected. Along the Georges River, alligator weed will grow on land as well as in freshwater and is tolerant to salt water (up to 10% salt by volume).

Various control measures have been tried with mixed success. Mechanical control is costly and usually has only a short term effect. Chemical control is only partially successful because only that part of the plant above the water can be killed. The stem that floats just below the surface of the water remains to shoot again. Trees, such as eucalypts

and she-oaks, and other plant life on the banks are very susceptible to the herbicide used to control alligator weed. Another undesirable aspect of this 'knock-down' type chemical control is the unpleasant smell produced by the rotting leaves that sink to the bottom of the river. The decaying leaves take oxygen out of the water, rendering it unsuitable for fish life.

Introduction from South America of two small insects that are the natural enemies of alligator weed may assist in controlling the infestation. The adults and larvae of the flea beetle (*Agasicles* spp.) are specific to alligator weed and feed on its leaves. The phycitid beetle (*Vogtia malloi*) bores into and eats the hollow stem of the weed allowing water to enter. After a period of time the remains of the stem become waterlogged and the plant drowns, as the leaves sink below the surface of the water. It seems likely that alligator weed will be controlled by biological means when its natural insect enemies are introduced to Australia in the near future.

Hedging one's evolutionary bets

from Montgomery Slatkin

ALTHOUGH population geneticists are not yet sure how natural selection acts on most of the genome—or even if it affects that much of the genome—there have been many predictions of the consequences of different kinds of selection. The hope has been that such models would help one to understand the dynamics of the gene pool of a population and would identify the kinds of natural selection which have been most important in evolution. Such models, however, despite fifty years of development are still far from that goal because of the inherent complexity of genetic systems and the large number of possible starting assumptions. Nonetheless, progress is being made and current models, of which Gillespie's is an example (*Genetics*, **76**, 601; 1974), are more realistic and potentially more useful than their predecessors.

One of the main problems in models of selection is the assumption about what is actually selected. Traditionally, and in keeping with Darwinian principles, the various genotypes have been assigned fitnesses which represent their relative contributions to the next generation. The fitness differences can be the result of either differential fecundity or mortality or both. Such models, however, do not take into account many of the effects produced by different patterns of reproduction. For example, in the simplest models, there would be no difference in fitness between two individuals one of which

Alligator weed on the Georges River near the Liverpool Golf Club at Casula in November 1973. The river is almost covered by mats of the weed. Earlier spraying has proved ineffective. This matted mass of 1 million tonnes of alligator weed was swept down the river by the mid-summer floods of 1974.

had ten offspring at once and the other of which had ten offspring one at a time: the average contribution of each individual to the next generation would be the same. It is obvious, however, that there would be a great difference between them; one is investigating its reproductive effort in one clutch and the other in ten clutches. If it were certain that a clutch would survive, regardless of its size, then clearly the variability in the number of offspring of the second individual would be much smaller than that of the first.

Until the publication of Gillespie's article, selection resulting from differential variance in offspring number had been ignored by theoreticians despite its obvious importance to the evolution of complex life histories. Gillespie shows that an allele which produces the same mean number of offspring but a smaller variance will increase in frequency and he argues that an important mechanism for reducing offspring variance is repeated reproduction and smaller clutch size. Gillespie deals only with a haploid population and, even then, the analysis is somewhat difficult. His simplification of the original model certainly needs more careful examination.

Although further mathematical work on the problem is needed, other results should support Gillespie's conclusion. Although many geneticists have assumed otherwise, the evolution of complex life histories involves more than simply the maximisation of reproductive potential.

OSSO

from our Chemical Physics Correspondent
No, the title of this piece is not an acronym for the Office for Senior Scientists' Obsolescence, that secret body which arranges for its 'clients' to be shunted into administration at 35 to make way for the next generation of research workers. It is rather the genuine chemical structure of a molecule recently characterised by Lovas, Tiemann and Johnson (*J. chem. Phys.*, **60**, 5005; 1974). It is formed, under conditions controlled as much by art as science, in the fairly high pressure, 10^4 Pa (100 mm Hg), microwave discharge in SO_2 . SO is a major product and the yield of it and its dimer seems to be a function of wall conditions as well as other components in the gas mixture. Careful lifetime studies have not yet been reported, but the half life is of the order of a few seconds under the flow conditions used. Polymeric deposits formed on the walls and some OSSO appeared in the gas phase when the surface was exposed to oxygen under discharge conditions.

The identification of OSSO was by means of a microwave spectroscopic

study which established (1) that the molecule was planar; (2) that it had a large dipole moment, 10.7×10^{-30} C m (3.17 debye), parallel to the intermediate axis of inertia; (3) that alternate rotational levels were absent, being forbidden by the spin statistics of a symmetrical molecule containing the bosons ^{16}O and ^{32}S ; (4) that there was a vibrational state, probably torsional, at about 140 cm^{-1} ; (5) that an analogue containing ^{34}S could be detected and that in it the full set of rotational levels was allowed. These facts, together with the values of the rotational constants, clearly show the species to be *cis*-OSSO, planar with C_{2v} symmetry.

The geometrical structure is then established with $r_{\text{SO}} = 145.8$ pm (1.458

Å), $r_{\text{SS}} = 202.45$ pm (2.0245 Å), and the SSO angle = 112.7° . This is a short S-O bond and a fairly long S-S bond so that the formula, $\text{O}^--\text{S}^+=\text{S}^+-\text{O}^-$, which matches classical valence rules, is in fact not very realistic, and the distribution of the six π electrons over the four centres is more delocalised than the above structure might imply. The characterisation of this molecule with its comparative stability is likely to catalyse further work on its electronic structure, on its vibrational and electronic spectra, and on a search for a possible *trans* form which, having no dipole moment, would not appear in the microwave spectrum. There could also be interest in isoelectronic species such as OSPF and FPPF.

Is history of science good for one?

from Robert Olby

In a recent article in *Science* (**183**, 1164-1172; 1974) the historian of physics, Brush, has described the "new look" which the history of science has acquired in recent years. Writing under the provocative title "Should the History of Science be rated X?", Brush pictures the old history of science as motivated by the search for approaches to modern scientific knowledge in the works of the past, thus to expose to view the progressive character of the development of science and its objectivity. Now the picture has changed and what Brush sees as emerging is the subjective manner in which scientific work and ideas are accepted or rejected. The roles of simplicity, analogy, unity and purpose seem to have been more important than mere empirical verification. To the believer in Galileo as the founder of the experimental method it comes as a shock to learn that the words "by experiment" were inserted in the English translation of the famous sentence "I have discovered by experiment some properties of [motion]"; or to see how the caloric theory of heat was overthrown not by the experiments of Count Rumford and Davy but by the acceptance of the wave theory of light and the analogies between light and heat.

The subjective and social features of scientific activity have been embodied in Kuhn's division of science into "normal" and "revolutionary". In a state of "normal science" the onus for proof lies with those who wish to overturn the established body of theory and practice (the

"paradigm") and not with those who uphold the paradigm. In this way the choice of problems as well as the significance accorded to experimental results tends to be determined by factors which are not purely rational and objective.

This type of approach to the history of science may be seen as subversive of the cult of scientific objectivity, so long regarded as essential to a scientist's education. Brush suggests not only that it furnishes a "more realistic picture of the behaviour of scientists", but also that it serves to soften the hard image of the "robot-like scientist lacking emotions and moral values".

Brush has, of course, expressed reservations to the "new look", he describes. He recognises that so eminent an American historian of science as Gillispie has argued for the objectivity of science. In Britain it is doubtful that an extreme relativist view of scientific knowledge has been established outside the gamut of the sociology of science. The British tend to believe that sufficient elements of such knowledge survive Kuhnian revolutions to justify the use of the words "development" and "progress". They would, at least, side with Bernard who judged progress in science by the criterion of the degree of control over the phenomena. They also recognise the distinction between what is irrational (counter to reason) and what is rational but devoid of any empirical supporting evidence. It is very doubtful that any but the most narrow-minded educators and the most gullible of students are discouraged by the historian's exposure of the rich and varied foundations upon which science has been erected.

Embryonic 'cold nose'

from a Correspondent

ANYBODY who opens a boiled egg at the blunt end will know there is an air space between the shell in this region and the rest of the egg contents. The usual explanation given for the function of this space is that it serves as a region for respiratory exchange between the embryo and the outside world; furthermore, the chick punctures the air space with its beak before hatching—a procedure which initiates respiration through the lungs and thus prepares the chick for its life outside. An additional function, which experiments on eggs of the domestic fowl and Japanese quail support, has recently been proposed by Simkiss (*J. Zool., Lond.*, **173**, 225; 1974). He argues that since loss of water by evaporation is one of the main problems associated with the development of an embryo in a closed or 'cleidoic' egg, any measure which limits such a loss would be of value.

When the parent bird is sitting on the nest the temperature of the egg and the humidity of the surrounding

air are both kept high so there is little loss of water vapour. But when the parent leaves the nest—and many birds are off the nest for periods of 5 to 15 minutes, 20–40% of the day—the temperature and humidity of the air surrounding the egg fall rapidly and, because the watery contents of the egg cool only slowly, there is a concentration gradient for water vapour to pass out of the egg; this loss of water from a warm wet body to cool dry air only stops, of course, when the parent returns or if the egg cools completely. The basis of Simkiss's argument is that the air held in the air space, because it has a low specific heat, cools rapidly when the parent leaves the nest thus reducing the gradient for the loss of water vapour through the shell. He estimates that in the climatic conditions of Britain the loss of water vapour per unit area of shell is 50% greater in those regions which overlie the liquid egg contents than in the region of the air space; with the air space region occupying about 40% of the area of the shell, he calculated a saving of about 15% during the period when a parent is not sitting.

It is, as Simkiss admits, difficult to assess whether this water-conserving

effect of the air space was more or less important in evolution than the respiratory advantages. Nevertheless, the comparative physiologist may well be able to throw light on the relative importance of the proposed functions, for one can think of climatic conditions in which some species breed but in which an air space would be of no advantage in water conservation, and species in which the egg is always kept warm by the parent.

Lasers probe the hydrogen atom

from B. P. Kibble

THE Doppler effect, which causes the apparent alteration in wavelength of the light emitted by moving atoms, has always limited the accuracy with which spectral line wavelengths, particularly those of atomic hydrogen, could be measured. But now this limitation has been overcome by saturated absorption techniques using lasers whose light can be tuned over a range of wavelengths. The first accurate measurements of a line in the hydrogen spectrum are reported by Hänsch and his colleagues at Stanford University in a recent issue

Lipmann's birthday party

from a Correspondent

THE name of Fritz Lipmann is such a commonplace in textbooks of biochemistry that many students of basic science may well be surprised to learn that, unlike Dalton and Archimedes, he is still alive and has in fact just celebrated his 75th birthday. To mark this event, eighty of his former students and colleagues attended a special symposium organised in his honour at the Max-Planck-Institut für Molekulare Genetik in Berlin-Dahlem, on July 7–9, to take part in a relaxing mixture of history, sentiment and science.

The Institut für Molekulare Genetik was an appropriate venue, for it was literally only a couple of hundred yards away that Lipmann's career really began, as an unpaid graduate student in the old Kaiser-Wilhelm-Institut in Dahlem. The institut, founded in 1910, had somehow managed to survive both the First World War and the German hyperinflation of the early 1920s, when Lipmann joined Meyerhof's laboratory there in 1927. At that time, the institut, which was of course the forerunner

of today's Max-Planck-Institut, was quite a small organisation and Lipmann and his contemporary Sir Hans Krebs gave an entertaining account of life there in the late 1920s, under the "benevolent dictatorship" of Meyerhof and Warburg, two rather forbidding characters. For instance, Sir Hans was advised on leaving the institut to take up another career, as his "chances of success in biochemistry were slight".

In 1930, Lipmann, with his wife and three years of postgraduate experience, set out for America to take up a one-year fellowship at the Rockefeller University. After that he worked for a few years in Copenhagen before returning to the United States to settle. First in Boston and later at the Rockefeller University, he proceeded to pour out his classical work on protein phosphorylation, "energy-rich bonds", coenzyme A, and a host of other topics. This diversity of interest was reflected in the scientific sessions of the symposium, in which the Lipmann alumni discussed on subjects ranging from bioenergetics to immunity in insects, and from ribosome structure to molecular biology in the reign of the Chinese Emperor Fu Hsi. The only common feature was the warmth of the tributes which

Fritz Lipmann

all the speakers paid to their former mentor. Finally a special lecture was given by Feodor Lynen of the Max-Planck-Institut für Biochemie on the isolation and characterisation of the biotin enzymes. This was the first 'Fritz Lipmann Lecture', a new event in the academic calendar, which will now be given annually in Germany as part of the programme of the Gesellschaft für Biologische Chemie, under the sponsorship of the Boehringer-Mannheim Corporation.

of *Physical Review Letters* (32, 1336; 1974), following their demonstration of the phenomenon in *Nature Physical Science* (235, 63; 1972).

In their experiment they studied the light absorbed rather than emitted by atoms. The intense light from a tuneable wavelength laser is shone on the atoms and is absorbed by a set of atoms whose component of velocity in the direction of the light enables the Doppler-shifted wavelength to be matched to their absorption. A weaker probe beam from the same laser, and therefore having the same wavelength, is made to travel in the opposite direction so it will be ignored by this set of atoms but absorbed by another set whose members have an equal and opposite velocity component. There is a special case when the wavelength is tuned to be such that the atoms which absorb the light are moving at right angles to the light paths and hence have a very small Doppler shift. Both sets then comprise the same atoms and these being partially saturated by the intense beam, absorb less of the probe beam. It is this decrease in absorption which is detected as a narrow signal without any appreciable Doppler width as the laser wavelength is tuned through the spectral line.

There is a double advantage in all this. First, the line-broadening Doppler effect, which previously blurred together the closely spaced fine structure components of the spectral line, is eliminated. Second, as this technique entails absorption of nearly monochromatic laser light the interferometer used to measure the wavelength can have a very small spectral range and a high resolving power; previously all the fine structure components were excited simultaneously in a lamp and the spectral range of the interferometer had to be large enough to encompass them all, with a consequent loss of resolution.

Hänsch *et al.* measured the absolute wavelengths of some fine structure components in the Balmer- α lines of hydrogen and deuterium to determine a value for the Rydberg constant, which characterises the wavelength of the spectral lines, and a value for the isotope shift between hydrogen and deuterium, which essentially measures the ratio of the mass of the electron to that of the proton. The accuracy achieved was an order of magnitude greater than that obtained by the emission technique.

Physicists in the past have used new techniques to measure accurately the spectrum of the hydrogen atom and in each successive instance the results have not agreed with the current theoretical description. Each consequent improvement of the theory has revolutionised physics—witness Bohr's

concept of stationary states which led to quantum theory. And again, cooling the hydrogen lamp in liquefied gases narrowed the spectral lines and revealed the fine structure which was ultimately explained by Dirac's relativistic formulation of the quantum theory. Here the requirement of negative energy states suggested the existence of the positron and brought about the science of elementary particle physics. Further minute discrepancies (Lamb shifts), confirmed by another new technique of radio-frequency spectroscopy, resulted in the quantum theory of radiation fields and particles, quantum electrodynamics (see Series, *The Spectrum of Atomic Hydrogen*; Oxford University Press 1957). Now measurements of increasing refinement can be anticipated using this latest technique of saturated absorption, particularly as what I have described is only one of a number of allied methods in which the natural resonances of atoms which give rise to their spectral lines can be explored by tuneable wavelength lasers. (One of these methods which is especially promising is two-photon absorption which has recently been demonstrated experimentally, see, for example, *Physics Today*, 27, 17; 1974.) Modern physics owes much to the exploration of the hydrogen atom at successively higher levels of precision and there is no reason to suppose that this process cannot continue.

Missing link in folding of trypsin inhibitor

from Barry Robson

A PARALLEL could be drawn between the folding of a globular protein and biological evolution in that both represent a transition from a state of disorder to one of order and function. Moreover, both processes have their missing links without which it is impossible to verify hypotheses concerning mechanism. The difficulty of finding the missing links in the folding of a globular protein is because the process is, for most proteins, approximately two state, involving unstable and short-lived intermediates which cannot normally be isolated. Three articles by Creighton (*J. molec. Biol.*, 87, 563, 579, 603–624; 1974) describe a procedure for trapping and characterising such intermediates.

As an experimental system, Creighton chooses bovine pancreatic trypsin inhibitor, a small protein of only 58 amino acid residues which inhibits the catalytic function of certain other proteins, including trypsin and chymotrypsin. The native structure of the inhibitor as obtained from living tis-

sue has been well characterised by X-ray crystallographic analysis (Huber *et al.*, *Naturwissenschaften*, 57, 389–392; 1970). As in the case of other globular proteins, the native structure is a compact, relatively rigid conformation maintained by non-covalent interactions (that is by van der Waal's, electrostatic, hydrogen bond and hydrophobic interactions), as well as by covalent disulphide bridges between cysteine residues. Trypsin inhibitor has three such disulphide bridges.

Since this compact, biologically active structure is to be the end point of the folding process, Creighton first unfolds the inhibitor in a concentrated solution of guanidinium chloride, which breaks the non-covalent interactions, and dithiothreitol, which breaks the disulphide bridges. In such conditions it is known that typical protein molecules assume highly flexible, open conformations which are, strictly speaking, not single states at all but a whole collection of conformational states of roughly equivalent energies separated by low conformational energy barriers. The importance of starting with this collection of states is that all the information for directing the folding process towards the native conformation must initially reside only in the sequence of amino acid residues characteristic of trypsin inhibitor and ultimately coded for in the chemical structure of the gene. It is therefore regrettable that the conformational disorder of the inhibitor was not actually proven before refolding, but only assumed by analogy to the behaviour of other proteins in these conditions. Although Creighton's indirect evidence for initial conformational randomness does not, however, exclude the possibility of a fairly high degree of residual conformational structure, nobody would deny that the absence of such structure is a reasonable bet which one hopes will be verified by future hydrodynamic tests.

Creighton initiates refolding of this assumed random structure by removing the guanidinium chloride by dilution and adding a disulphide reagent such as oxidised dithiothreitol. The refolding reaction is then quenched at different times by the addition of iodoacetate or iodoacetamide which stop the further making and breaking of disulphide bridges. The species so trapped at various stages of refolding are subsequently analysed by acrylamide gel electrophoresis.

When any remaining unbridged residues of the trapped intermediates are carboxymethylated, the relative mobilities of the intermediates in the acrylamide gel reveal that some contain one and some two disulphide bridges. Consideration of the time course of the appearance and disap-

pearance of these intermediates shows that the folding can be considered to occur in three steps, each associated with the appearance of a further disulphide bridge. The first step is the formation of one-disulphide intermediates which are in rapid equilibrium with each other. The rate-limiting step in their disappearance is the formation of two-disulphide intermediates which are rapidly converted by the formation of the third bridge into the biologically active inhibitor.

Those intermediates with one disulphide bridge are more closely investigated, largely because results concerning the two-disulphide intermediates are less reproducible. The most abundant species of single disulphide intermediates has a disulphide bridge between cys residues at positions 30 and 51 in the amino acid sequence, and constitutes about half the population of single-disulphide molecules. The next most abundant species has a disulphide bridge between cys-5 and cys-30, and constitutes about one quarter of the population. Two minor species, involving bridges between cys-30 and cys-55 and between cys-5 and cys-51, are also detectable.

Returning to the analogy with biological evolution, the importance of the predominating species with a bridge at cys-30 to cys-51 is that this bridge constitutes a 'living fossil' in the sense that it survives to appear in the native, folded structure. Contemporary theories of protein folding lay great emphasis on the importance of such 'living fossils'. It is widely held that local arrangements of the backbone of the protein, such as α helix and β -pleated sheet, form early during the folding but survive to appear in the native structure because of their intrinsic stability. Since none of the other detectable disulphide bridging arrangements appears in the native structure, it is interesting to consider whether the 30-51 bridge fits in with this notion. Creighton points out that in the native structure cys-30 occurs in the middle of a β -pleated sheet region and cys-51 in the middle of an α -helical region. Since the initial formation of helix and pleated sheet regions is generally supposed to be followed by mutual association, the early appearance of a bridge between cys-30 and cys-51 is consistent with the early appearance of the helix and pleated sheet features in which they occur.

A further bonus is that the early formation of the β -pleated sheet region would account for the correct threading of the backbone. Correct threading is a particular problem for trypsin inhibitor because to arrive at the native conformation the backbone must be passed through the loop formed by the 30-51 bridge. Without the initial

formation of the β -pleated sheet, it would be hard to see the factors which select for correctly threaded molecules.

Because of the emphasis on disulphide bridging it might seem paradoxical that the usefulness of Creighton's results depends on cys residues not having a special role in the folding of proteins. In fact it is crucial that disulphide bridges form only when the conformation of the molecule, determined by other factors, will permit. Hence the trapping of the disulphide intermediates is intended merely to be a device for freezing the folding process at any moment in time and it is hoped that the disulphide bridges which form are an effect, never a cause, of the conformational preferences of the intermediates. In order to satisfy this ideal it is necessary that an interaction between cys residues is no stronger than non-covalent interactions between other sidechains at the time of folding. Although the covalent nature of the disulphide bridge would seem to make this an unrealistic ideal, the disulphide bond is in fact a labile association whose stability is determined by the reducing potential of the environment. It is therefore very pertinent that, as pointed out by Creighton, trypsin inhibitor is synthesised biologically in conditions where the reducing potential actually disfavors disulphide bridge formation. Evidence summarised by Creighton would seem to suggest that cys residues are cunningly placed by nature so as to form stabilising disulphide bridges in an extracellular oxidising environment, but that they have no relevance to the normal folding process.

The most general conclusion of this work is that a non-random mixture of conformations can be formed early during the folding process, and that some of the features of the most abundant intermediates may survive to appear in the native conformation. The most important result specific to trypsin inhibitor is that the missing link from the early stages of folding is represented by the disulphide bridge cys-30 to cys-51.

Meteorites and rabbits

from David W. Hughes

THE collection of meteorites in the Australian Museum has increased enormously in the past few years, and a large portion of the new material has resulted from the activities and interests of a group of rabbit trappers who criss-cross the Nullabor Plain on motor cycles. In fact, out of 36 meteorites recovered from the plain 24 were found by the members of one family, the Carlises. The added involvement of the Kalgoorlie School of

Mines and the Western Australian Museum has increased the rate of detection of meteorites from 16 per decade, which remained constant between 1897 and 1966, to around 80 per decade since 1966.

Until the latest count (*Rec. Austr. Mus.*, 29, 169; 1974), reported by Mason (Smithsonian Institution, Washington DC), irons formed the most numerous group of Australian meteorites. This is in marked contrast to general world statistics, in which stones predominate. A possible explanation for this is that meteoritic iron may have provided raw material for swords and ploughshares. Iron meteorites would therefore have been consumed rapidly once a native people had acquired the facility for working metal. Significantly, that facility is not possessed by the Australian aborigine. Stone meteorites, which had no practical use, were invariably worshipped. Moslem pilgrims to Mecca pay homage to the sacred black stone of Kaaba, and in Japan the Ogi meteorites were worshipped for 150 years in the belief that they were weights which had fallen from the loom of the Goddess Shokujo who lived on the shores of the Heavenly River (the Milky Way).

The problems of estimating the influx of meteorites and the ratio between stones and irons have been discussed by Nininger (*Out of the Sky, an Introduction to Meteoritics*, Dover New York; 1952) who searched for witnessed and unwitnessed meteorite falls for more than 30 years. Campaigns among rural populations in the United States were designed to acquaint farmers and ranch dwellers with the appearance and importance of meteorites. Directions were given for simple field tests to distinguish meteorites from terrestrial rocks and a price was offered for specimens as an inducement to all to keep on the lookout and report them. The programme was very successful: the number of finds increased dramatically and eventually the content of the Nininger Collection nearly mirrored the prevalence of meteorites in space (where irons make up 6% by number, stony-iron 2%, and stones 92%).

In Australia the intensive prospecting for gold and other minerals led people to expect a reasonable yield of meteorites. But, unfortunately, the prospectors avoided the flat, sandy, desert regions of the interior plains where meteorites would be more obvious. Stockmen and ploughmen may have found meteorites but, unlike the prospector, they generally had no interest in unusual rocks. On the Nullabor Plains, however, the personnel at the Kalgoorlie School of Mines have encouraged an active interest among the rabbit trappers.

Nitrosoguanidine mutagenesis during nuclear and mitochondrial gene replication

Ian W. Dawes and Bruce L. A. Carter

Departments of Microbiology and Zoology, University of Edinburgh, Edinburgh EH9 3JG, UK

The timing of individual nuclear gene replication during S phase in an eukaryote can now be studied by nitrosoguanidine mutagenesis. Using this technique, results also suggested that mitochondrial DNA replication is synchronous and a late event in the cell cycle.

In prokaryotes the mutagen N-methyl-N'-nitro-N-nitrosoguanidine (NG) is thought to induce mutations selectively at the DNA replication fork^{1,2} and NG mutagenesis at different stages of the cell cycle has provided information on the order and timing of individual gene replication³.

In eukaryotes, techniques do not exist for determining the ordering of DNA replication at the gene level. We have therefore tested whether NG induces mutations during DNA replication in yeast and whether the temporal ordering of replication of genes on individual chromosomes and the timing of replication of chromosomes relative to each other is feasible using the NG mutagenesis technique.

The budding yeast, *Saccharomyces cerevisiae*, is an appropriate test organism. Nuclear DNA synthesis occurs during a restricted period of the cell-cycle which can be divided into G1, S, G2 and M phases⁴. Yeast populations can be synchronised or fractionated according to cell age^{5,6} in the division cycle. An adequate genetic map has been developed with most of the 17 known chromosomes well marked⁷ and NG has been shown to be an effective mutagen⁸.

In addition to the nuclear genetic complement, yeast mitochondria contain mitochondrial DNA (mit DNA). Using the best available estimate⁹, each haploid cell contains about 50 mit DNA molecules. A few markers on the mitochondrial genome have been identified and progress has been made in constructing a genetic map¹⁰. The pattern of mit DNA synthesis during the yeast cell cycle has been the subject of conflicting reports. Cottrell and Avers, using *S. cerevisiae*, and Smith *et al.* with *Saccharomyces lactis*, concluded that the replication of mit DNA occurs over a restricted period at a different stage in the cell cycle to nuclear DNA replication^{11,12}. Williamson and Moustacchi, however, observed that mit DNA synthesis was continuous throughout the cell cycle in *S. cerevisiae*¹³.

If NG treatment of yeast results in enhanced mutation at the replication fork for both nuclear and mit DNA it should be possible to delineate both periods of synthesis within the cell cycle. If mit DNA synthesis is synchronous and occurs during a restricted part of the cell cycle different from that for nuclear DNA synthesis, then mutations showing mitochondrial inheritance should be induced by NG only during that part of the cell cycle. ••

To study the effect of NG on both nuclear and mit DNA, readily detectable forward mutations are required. Those for acquisition of resistance to antibiotics affecting mitochondrial functions are suitable because resistance to erythromycin¹⁴ or oligomycin¹⁵ can arise by nuclear- or mitochondrially-inherited mutation.

As yeast cells increase in size throughout the cell cycle and can be separated according to size by zonal rotor centrifugation, the cell cycle is represented across the rotor after centrifugation of an exponential culture.

Cell age during the cell cycle is approximately linearly related to fraction number obtained from the zonal rotor in our conditions. This was shown by measuring mean cell volumes during growth of a synchronous culture and in a different experiment in fractions obtained after zonal rotor

Fig. 1 Average total DNA content per cell as a function of cell age in the cell cycle. Exponential cultures of strain ID-1 grown to log phase in YEPG at 30°C were separated into fractions of various cell cycle age by zonal rotor centrifugation. For each fraction total DNA content was estimated by the Giles and Myers method²⁰ and cell concentration was determined by electronic particle counting. Fraction number from the zonal rotor is a linear function of cell age in the cell cycle.

Fig. 2 NG-induced mutagenesis to ER^+ as a function of cell age. An exponential population of strain ID-1 grown to 10^7 cells ml^{-1} on YEPG at $30^\circ C$ was washed by centrifugation in sterile $0.2 M$ potassium acetate (KAc; pH 5.5) and resuspended in KAc containing NG ($0.5 mg\ ml^{-1}$). After 15 min at $30^\circ C$ the cells were centrifuged, resuspended in $40 ml$ sterile water and separated into fractions in the zonal rotor. Viable cell concentration in each fraction was determined by counting on YEPD plates. ER^+ mutants in each fraction were scored after 4 d (○) and 7 d (●) by plating between 10^6 and 10^7 survivors on to each of six YEPG plates containing $0.4 mg$ erythromycin ml^{-1} .

centrifugation of an exponential population. Cell age from the synchronous culture plotted against fraction number in which the mean cell volume was identical gave a near linear curve.

Figure 1 shows the average DNA content per cell for fractions obtained by zonal rotor centrifugation of strain ID-1 growing exponentially in YEPG medium (1% yeast extract, 2% bactopectone, 3% glycerol; mean generation time: 3.5 h). As the zonal rotor separates yeast populations into fractions according to stage in the cell cycle, and the majority of DNA in the yeast cell is nuclear DNA (ref. 4), it is clear that nuclear DNA replication in ID-1 takes place mainly during the second quarter of the cell cycle, as in other strains of *S. cerevisiae*.

Mutation frequency as function of cell age

An exponential culture of ID-1 growing on YEPG was exposed to NG ($0.5 mg\ ml^{-1}$) for a brief part (15 min) of the cell cycle (3.5 h) and separated into fractions according to cell age. The distribution of mutants resistant to $0.4 mg\ ml^{-1}$ erythromycin (ER^+) as a function of cell position on the zonal rotor is shown in Fig. 2. These data were plotted for mutants appearing on plates after 4 d and 7 d incubation. As similar results were obtained on plotting mutants per total cells in each fraction NG inactivation was not markedly cell cycle dependent.

NG-induced mutation to ER^+ occurred at an increased frequency in two regions of the cell cycle (represented by fractions 7-14 and 22-25 in Fig. 4). Three peaks of suscept-

ibility to mutagenesis to ER^+ (fractions 7, 11 and 14) were found in the initial period of mutant induction coincident with nuclear DNA synthesis (Fig. 1). In contrast, ER^+ mutants induced later in the cell cycle were found in a single large peak (fractions 22 and 23) in a region of the rotor containing cells close to cell division. Mutants induced in later fractions of the zonal rotor appeared earlier on selective plates than most of those in fractions 7 to 14, indicating possible differences in these two groups of mutants.

If NG acts mainly at the replication point in *S. cerevisiae*, ER^+ mutants induced in fractions 7-14 during S phase should show normal Mendelian segregation of the resistance marker from the cross to a sensitive strain. Results of the relevant genetic tests are summarised in Table 1. Most (seven of nine tested) of the mutants in fractions 7, 11 and 14 were the result of a nuclear mutation, the other two were cytoplasmic. All mutations in fractions 22 and 23 were cytoplasmically-inherited on the basis of the following criteria. First, the segregation of stable mutant and wild-type diploid cells during vegetative division of the diploid formed from a cross of the mutant to a sensitive strain; second, the tetrad ratios of 4:0 and 0:4 (sensitive:resistant) following meiosis of diploids formed in a cross with a sensitive strain; third, most ρ^- -petites derived from the resistant mutants by continuing exposure to ethidium bromide led to sensitive diploids on crossing with a sensitive strain.

By testing 16 mutants from each fraction, it was found that nuclear ER^+ mutations in fraction 14 differed from

Table 1 Characteristics of ER^+ mutants from the zonal rotor fractions

Fraction/mutant		Cross to sensitive strain Diploid phenotype*	Ascus segregation of resistance	Effect of ethidium bromide†
7	1	Mixed	4:0 and 0:4	Loss
	2	Sensitive‡	2:2	Retention
	3	Sensitive‡	2:2	Retention
11	1	Sensitive‡	2:2	Retention
	2	Sensitive‡	2:2	Retention
	3	Mixed	4:0 and 0:4	Loss
14	1	Resistant	2:2	Retention
	2	Resistant	2:2	Retention
	3	Resistant	2:2	Retention
22	1	Mixed	4:0 and 0:4	Loss
	2	Mixed	4:0 and 0:4	Loss
	3	Mixed	4:0 and 0:4	Loss
23	1	Mixed	4:0 and 0:4	Loss
	2	Mixed	4:0 and 0:4	Loss
	3	Mixed	4:0 and 0:4	Loss

* Mutants were crossed to an ER^+ strain and diploid clones tested for resistance or sensitivity to the antibiotic.

† Mutants were treated with ethidium bromide to produce petites and these were crossed to a grande sensitive strain. Diploids so formed were tested for presence or absence of resistance allele directly or after tetrad dissection.

‡ Diploids showed slight growth on selective plates.

those in the other two nuclear peaks in being completely dominant to the ER^+ allele. If the peaks in susceptibility to mutation during nuclear DNA replication represent mutation at different loci, recombination between them should be possible. Random spore analysis of the cross between haploids carrying mutations 11.2 and 14.1 (derived from the $ER^+ \times ER^+$ dissections) indicated that linkage was not detectable by this method as approximately 25% ER^+ recombinants were recovered (8 from a total of 35 spores). Analysis of the crosses of mutants derived from fraction 7 with those from 11 or 14 was not satisfactory

because of poor viability of spores and inability to disrupt tetrads in these crosses, although several ER^+ spores (two out of five) were recovered from the cross 7.2 with 14.1.

Mutation to oligomycin resistance

As mitochondrial mutation to ER^+ represents mutation in a restricted region of the mitochondrial genome it is important to study other mitochondrial loci distinct from those for resistance to erythromycin. Those for resistance to oligomycin, a mitochondrial ATPase inhibitor, are suitable as they are not linked to the segment of the mitochondrial genome specifying functions of mitochondrial ribosomes¹⁰.

Figure 3 shows the frequency of induction of OL^+ and ER^+ mutants as a function of cell age. An exponential culture of ID-1 was treated with NG, separated into fractions according to cell age and assayed for mutants resistant to either antibiotic. OL^+ is induced at the same stages of the cycle as ER^+ , particularly for the later part of the cell cycle in which OL^+ and ER^+ mutants reached peak concentration in the same fraction. During the S phase there were two main peaks of susceptibility to mutation to OL^+ . These occurred within the same cell age range as those for resistance to erythromycin although in one case at least the OL^+ mutation was induced in cells of different age from those for ER^+ . This result is expected as the sites of action of the two antibiotics differ, erythromycin inhibiting mitochondrial protein synthesis whereas oligomycin inhibits the mitochondrial inner membrane ATPase complex. Nuclear mutations conferring resistance to one antibiotic need not necessarily confer resistance to the other.

Preliminary characterisation of the various fractions had led to the identification of cytoplasmically-inherited OL^+ mutations from the late peak of mutants in Fig. 3. These

were mixed with a fairly high background of nuclear mutants, in contrast with the ER^+ mutants in which the nuclear region was contaminated with a low background of those of cytoplasmic origin. The majority of ER^+ mutants tested were OL^+ .

At concentrations similar to those used for yeast mutagenesis, NG induces up to 40% petites in *S. cerevisiae*. If this is due to a direct mutagenic effect of NG at a few specific loci, as seen in the induction of drug resistance, the fraction of petites in survivors from NG mutagenesis should

Fig. 4 Petite induction by NG during the cell cycle. Plates used for estimating viable cell concentrations in the experiment shown in Fig. 2 were used to determine the percentage of petites among survivors by the triphenyltetrazolium chloride agar overlay technique of Ogur *et al.*²¹.

Fig. 3 Comparison between induction of OL^+ and ER^+ mutants by NG during the cell cycle. Experimental details were as those in the legend to Fig. 2. OL^+ mutants (\circ) were scored after 4 d incubation at 30°C on YEPG plates containing 6 μ g oligomycin ml^{-1} . ER^+ mutants (\bullet) were scored after 5 d.

show similar variations with cell age. Petites were not induced by NG in the same way as drug resistance but were found in all fractions from the zonal rotor at a frequency of 20% in young cells continuously decreasing to 10% in doublets (Fig. 4).

DNA replication and NG mutagenesis

Evidence that NG-induced mutation occurs primarily at the DNA replication point derives mainly from prokaryotic studies and is based on the observation in synchronous cultures of a correlation between the time during the cell cycle of induced reversion at a locus with its map order on the bacterial chromosome¹. Furthermore, in *Escherichia coli* and *Salmonella typhimurium*, NG induces double mutations at high frequency and these usually show close linkage².

In eukaryotes, NG-induced mutation at enhanced rates during DNA replication has been shown in *Chlamydomonas reinhardtii*¹⁷. In this system a slight increase in mutation at a cytoplasmic locus was found during chloroplast DNA replication. The results with yeast extend these observations to show that mutation at a specific nuclear locus (for example that conferring 'dominant ER^+ ') occurs only during a brief interval of the S phase, and that different loci are sensitive at different points in the S phase. We presume that

this is a result of mutagenesis in loci replicating at different times during S phase. This differential sensitivity, and its correlation with the period of nuclear DNA replication, makes it unlikely that selective NG mutagenesis is the result of changes in membrane permeability or detoxification of the mutagen during the cell cycle.

Regardless of the molecular mechanism by which NG mutagenesis is correlated with the process of DNA replication, it may now be feasible to map the temporal ordering of chromosomal replication in an eukaryote in much more detail than hitherto has been possible, as mutations in different loci replicating at different times during S phase can be resolved by zonal centrifugation.

Autoradiographic studies of a number of eukaryotes have shown that chromosomal replication follows a sequential and heritable pattern¹⁸. For example, certain chromosomes and regions of chromosomes consistently replicate late in successive cell cycles and in *Physarum* DNA replicated at a particular point in one S period is replicated at the same point in the next S phase¹⁹. Our experiments extend this observation to the level of individual gene replication. In spite of the existence of 17 chromosomes in *S. cerevisiae* and the probable existence of multiple replication origins on each chromosome, duplication of a particular locus always occurs at a fixed time in the S phase of the cell cycle since it is possible to distinguish separate peaks of NG-induced mutation at different nuclear loci after zonal centrifugation.

Mitochondrial DNA replication

Haploid yeast cells apparently contain approximately 50 circular mit-DNA molecules, each 25 μ m long⁴. If NG acts selectively during mit DNA replication, the simplest interpretation of our data on coincident induction of cytoplasmic ER⁺ and OL⁺ mutations is that all copies of these two genetically distinct regions of the mitochondrial genome are replicated during the same brief interval late in the cell cycle. It is possible that all copies of the complete mitochondrial genome are replicated synchronously late in the cell cycle.

The hypothesis that mit DNA replication is periodic and a late event in the cell cycle is consistent with some biochemical data for diploid *S. cerevisiae*¹¹ and *S. lactis*¹² but differs from that of Williamson and Moustacchi who reported continuous synthesis of mit DNA in diploid *S. cerevisiae* populations synchronised by alternate feeding and starving¹³. The direct test of these alternatives will come from biochemical assays of mit DNA replication.

These discrepancies may be due to strain differences, or may result from varying approaches in studying the cell cycle. Our experiments examine a normal cell cycle as exponential cultures are treated with the mutagen and then separated according to stage in the cell cycle. Feeding and starving is a form of induction synchronisation and may not result in a normal cell cycle because artefacts resulting from metabolic disturbance and failure to synchronise all cell activities¹⁸ can occur during induction methods. Mitchison has shown the cell cycle is comprised of two cycles, the growth and the DNA-division cycles. The former is not synchronised by induction methods, and some events which normally occur periodically during the cell cycle appear continuously¹⁹.

Our results show a striking difference between petite induction and mutagenesis to antibiotic resistance. Petites were induced at all stages of the cell cycle, at a rate 10,000 times greater per survivor than mutation to ER⁺. This could be indicative of a fundamental difference between the mode of petite induction and the mechanism of mutagenesis by NG. NG is known to alter the activity of proteins²² and if as

suggested by Williamson⁹, a repression mechanism operates to regulate mitochondrial integrity, NG could act in petite induction by causing a phenotypic alternation in the activity of a repressor. This would be distinct from a mutagenic process as is the induction of petites by 5-fluorouracil⁹.

It is frequently difficult to demonstrate activity of mutagenic compounds in induction of mitochondrial mutation. The recovery of a peak of mitochondrial mutants at late stages in the cell cycle following NG treatment indicates that this compound is an effective mutagen for the mitochondrial genome.

NG mutagenesis, in conjunction with techniques for separation of populations according to the stage reached in the cell cycle provides a powerful selective technique for enrichment of particular mutants, and the ability to 'direct' mutagenesis discussed by Cerdà-Olmedo *et al.*¹ may now be possible in eukaryotes.

NG induces mutations conferring resistance to antibiotics affecting mitochondrial function at two stages of the cell cycle. One stage is coincident with nuclear DNA replication while the other is late in the cell cycle and may be that at which mitochondrial genes are replicated. A particular nuclear gene is susceptible to NG mutagenesis only at a specific time during S phase and different unlinked nuclear genes are sensitive at different times during S phase. NG is presumed to act during gene replication, and it should therefore be possible to determine in yeast the temporal pattern of chromosomal replication at the gene level.

We thank Professors Charlotte Auerbach and J. M. Mitchison and Dr D. H. Williamson for helpful discussion and advice and I. D. Hardie and R. Pitcairn for technical assistance. This research was supported by the Science Research Council.

Educability and group differences

Arthur R. Jensen

Institute of Human Learning, University of California, Berkeley, California 94720

Professor Jensen replies to criticism of his book Educability and Group Differences made by Professor J. M. Thoday in a review published in Nature.

I WISH to reply to the two main points of criticism made in the review of my book, *Educability and Group Differences*, (Methuen, London, 1973) by Professor J. M. Thoday in *Nature* (245, 418–420; 1973).

I had reported that when white and negro children were matched for a particular IQ score, say 120, the siblings of the two racial groups differ in average IQ, and that the difference is consistent with the phenomenon known as 'regression to the mean'. The white siblings regress toward the white population mean IQ of 100, the negro siblings toward the negro population mean of 85. The amount of regression is predictable in both racial groups from a genetic model in which the genetic correlation between sibs is 0.05 and the heritability, h^2 , of IQ is 0.80. The same model, using different empirically estimated values for h^2 , is applicable to any other continuous traits, such as height, weight, and fingerprint ridges. (In the present example, approximately the same amount of sibling regression was found for height as for IQ, and the same equation predicts as well for negroes as for whites.) All these findings are consistent with an already existing polygenic model which has proven theoretically valuable in understanding variation in metrical characteristics, physical and behavioural.

Factor X

But Thoday claims that a finding such as I reported "... adds nothing whatsoever to the strength of the genetic hypothesis" on the ground that the evidence is also as compatible with an explanation in terms of a hypothetical environmental "factor X" as in terms of the genetic hypothesis. But "factor X" is, of course, a purely *ad hoc* hypothesis. No previous environmentalist theory or model has been put forth which would have predicted the quantitative aspects of these findings, nor the linearity of regression throughout the middle 98% of the IQ range, nor the similarity of regression for IQ, height, and weight, nor the fact that the same regression equation works equally well for both racial groups. All these points, which are consistent with a much larger body of genetical theory and findings applicable to all organisms, would have to be regarded as coincidences in terms of the purely *ad hoc* hypothesis that some as yet unidentified environmental "factor X" is responsible. The findings, of course, cannot prove or disprove any *ad hoc* hypothesis which is invented expressly to explain them. But the fact that they are consistent with a genetic model which is not *ad hoc* is a point in favour of the genetic explanation. Philosophers of science, I believe, would support my contention. In fact, a forthcoming article, "Progress and Degeneration in the IQ Debate" by Dr Peter Urbach (*Br. J. Phil. Sci.*) argues that the chief weakness of the environmentalist position is its extreme recourse

to *ad hoc* explanations, often mutually inconsistent, of findings which were predicted by, or which easily fit into the framework of, already existing genetical theories supported by a growing internally-consistent network of evidence.

Thoday's second criticism is intended as an example of uncritical acceptance by me of some evidence which seems to favour a genetic hypothesis.

It involves my reference to a published study by DeLemos, which shows that a sample of full Australian aboriginals performed significantly less well on several of Piaget's tests of conservation than did part aboriginals (with the average genetic equivalent of one Caucasian greatgrandparent), despite the fact that the two groups shared much the same general environment without any distinguishable systematic environmental differences between the full and part aboriginals. Since the Piagetian tests, which are intended to reflect changes in mental maturity, are sensitive to age differences, and DeLemos's subjects ranged in age from 8–15 yr, Thoday conjectures that the findings reported by DeLemos could be an artefact of her not having controlled for age. The much more detailed presentation of the data and other analyses in DeLemos's PhD thesis (460 pages), of which I obtained a microfilm copy in 1967 and on which her later published article was based, however, shows that Thoday's statement that "the data cannot be regarded as demonstrating that the ancestry difference has significant effects" is not borne out by the evidence. Nor did I notice any other likely artefacts in my reading of DeLemos's thesis. My personal discussion of this research with Dr DeLemos, in 1969, added to my confidence in her conduct and analysis of the study.

Partial correlations

The invalidity of Thoday's conjecture can be demonstrated perhaps most simply by a reanalysis of the original data provided by DeLemos, using partial correlations. I have performed this analysis, based on all 80 subjects from the Hermannsburg group (42 full and 38 part aboriginals) ranging in age from 8–15 yr. Intercorrelations were obtained between age in months, the exact percentage of Caucasian ancestry, and total score on the six tests of conservation (each test scores as 0, nonconservation, 1, transitional; 2, conservation). The zero order correlations among these variables are: age \times %Caucasian ancestry: $r=0.192$ ($P<0.05$); age \times total conservation score: $r=0.350$ ($P<0.01$); %Caucasian ancestry \times total conservation score: $r=0.478$ ($P<0.01$). If the correlation between ancestry and conservation score depends upon the correlation of each of these variables with the third variable, age, for example, then the partial correlation between ancestry and conservation, with the effect of age statistically held constant, should be reduced to a value not significantly greater than zero. If, on the other hand, the partial correlation is significant, it means that ancestry makes some contribution to the conservation score independently of age. The partial correlation between Caucasian ancestry and conservation score turns out (independent of age) to be 0.448, which is significantly greater than zero at the 1% level of confidence. A more

complex type of analysis (ANOVA of total conservation scores, with ancestry nested within 1 yr age groups), too involved to present here but which does not make any assumptions about linearity of regressions as is implicit in partial correlations, fully supports this conclusion that DeLemos's finding is not attributable to age differences between the full and part aboriginals. Also, it can be shown that the sex of the subjects has no significant relationship to any of the other variables in DeLemos's study.

The fact that another study of conservation in full and part aborigines, by Dasen (published in 1972, after my citation of the DeLemos study was in press), failed to find a significant relationship between ancestry and conservation

performance does not automatically invalidate the DeLemos study, which appears methodologically at least as sound as the Dasen study. The latter involved certain procedural and sampling differences, so that it cannot be regarded as a true attempt at replication of the DeLemos study. Dasen's discrepant findings do mean, however, that the findings by both DeLemos and Dasen are not clearly understood in terms of the procedural variables affecting performance and that neither's results are generalisable to the general population of aboriginals or to other tests of conservation. The only answer for this state of affairs, which is of course a common occurrence in empirical research, is to systematically pursue further investigations in the same vein.

letters to nature

Absence of soft X rays from Eta Carinae

THE X-ray telescopes on OAO-Copernicus have been used to search for X-ray emission from η Carinae. The instrumentation has been described elsewhere¹⁻²; briefly, it comprises two paraboloidal X-ray telescopes operating in the energy ranges 0.5–1.5 and 1.5–4.6 keV, with a separate collimated proportional counter operating from 2.5–7.5 keV.

The energy source of η Car, first seen in the optical spectrum³ and now in the infrared⁴, is not yet entirely clear⁵⁻⁶. Thackeray⁵ suggested that it belongs to a new, slow class of supernovae associated with the birth of an expanding stellar association, and Ostriker and Gunn⁷ have developed a supernova model of large mass ($\approx 50M_{\odot}$) energised by a central neutron star and emitting synchrotron radiation from the surrounding nebula in the optical and infrared⁸. Alternatively⁶, the object may be a very massive star ($600\text{--}100M_{\odot}$) which is vibrationally unstable and has ejected a fraction of a solar mass to form the observed nebulae and condensations⁹; or it could be a very young massive star approaching the main sequence^{3,6}. On either of these last two hypotheses the radiation is entirely thermal: the optical continuum results from a hot central star or from two-photon emission from metastable hydrogen, and is distorted by reddening in a circumstellar dust cloud¹⁰ which re-emits the absorbed radiation in the infrared^{11,12}. The thermal model, more probably involving a hot central star, is strongly supported by the relative intensities of emission lines of hydrogen¹³ and permitted¹⁴ and forbidden¹⁰ FeII, by the detailed analysis of Davidson¹⁵ and by the presence of silicate bands near $10\text{ }\mu\text{m}$ (ref. 16); but measured intensities of [S II] lines do not show the expected intrinsic reddening¹⁷.

On the synchrotron model, inverse Compton scattering may lead to an observable X-ray flux¹⁸, which would probably be accompanied by intense synchrotron X rays if the 'pulsar' mechanism were operative. On either model the observations of an expanding shell moving out into the surrounding medium must imply the presence of a shock wave with compression and heating of the ambient gas to a temperature at which the emission of X rays becomes important. An observation of η Car in X rays would therefore be of great value in helping to decide between the two models and in setting constraints of the physical parameters involved.

A soft X-ray source found in a scanning rocket experiment¹⁹ was located somewhere near the galactic equator and within 0.3° of the galactic longitude of η Car, with which it was tentatively identified. This unconfirmed identification led Davidson and Ostriker²⁰ to comment on the parameters of the thermalised shock front which precedes the expanding shell and which was assumed to account for the X rays observed below

2.7 keV. They concluded that the shell must be moving into a surrounding medium of density $\sim 2,000\text{ cm}^{-3}$, which was rather difficult to account for, because it implied that η Car had not cleared a cavity around itself by mass outflow before the large outburst of 1843. Another possible consequence of this model is that the green coronal line [FeXIV] λ 5,303 may be present in the visible spectrum²¹. A spectral tracing from the Radcliffe Observatory indicates that this line, if present at all, is considerably weaker than predicted, but this negative result cannot be treated as a very conclusive test of the shock model. The pulsar model seems, on the other hand, to have been ruled out by the steep slope and modest intensity of the observed X-ray flux²⁰, even if the identification¹⁹ with η Car were correct.

Eta Car was observed by the X-ray telescopes on board OAO-Copernicus on May 25, 1973. Both telescopes used the largest field of view (equivalent beam width 12 arc min) and were pointed 'on' and then 'off' the source for six sets of observations of about 14 min each. The slew 'off' the source was of about 5° in range, and provided a reliable background estimate. No statistically significant difference in count rate was observed in either telescope, which leads to the upper limits (at the 2σ level) shown in Table 1. Similarly, no significant count rate was

Table 1 Upper limits to the X-ray flux from η Carinae

Energy band (keV)	0.5–1.5	1.5–4.6	2.5–7.5
Total count rate (s^{-1})	<0.01	<0.13	<0.025
Maximum energy flux in band erg $\text{cm}^{-2}\text{s}^{-1}$	1.6×10^{-11} *	4×10^{-11} *	2×10^{-11} †

* Assuming thermal spectrum¹⁷ $kT = 0.26\text{ keV}$, and hydrogen column density $N_H = 3 \times 10^{21}\text{ cm}^{-2}$

† Assuming a synchrotron spectrum, $\alpha = 0.8$ (ref. 16).

recorded in the collimated proportional detector, which has a 3° field of view; the corresponding upper limit (Table 1) is slightly below the threshold of the third Uhuru catalogue of X-ray sources²², which is $3.4 \times 10^{-11}\text{ erg cm}^{-2}\text{ s}^{-1}$ (2 Uhuru units) over the energy range 2–6 keV. An upper limit to the X-ray luminosity L_x of the source, between 0.5 keV and 7.5 keV can be obtained by removing the assumed effect of a column density $N_H = 3 \times 10^{21}\text{ cm}^{-2}$ on the maximum flux observed in the 0.5–1.5 keV band and extrapolating the continuum to higher energies. Assuming a distance of 2 kpc, this gives $L_x < 2 \times 10^{34}\text{ erg s}^{-1}$; the result is approximately the same whether the thermal ($kT = 0.26\text{ keV}$) or synchrotron ($\alpha = 0.8$) spectrum is assumed, and does not vary significantly for N_H values between 2.5 and $4.8 \times 10^{21}\text{ cm}^{-2}$. The interstellar cross sections used here are those of Brown and Gould²³.

The low energy flux (0.5–1.5 keV) is at least an order of magnitude below that expected from the Livermore source.¹⁹ Possible explanations for this disparity are:

- (1) that the source found by Hill *et al.*¹⁹ was not η Car but was instead a soft source some distance away in galactic latitude;
- (2) that the observed emission¹⁹ came from an extended region around η Car at least 1° in diameter
- (3) that the X-ray flux from η Car is variable.

In the second case the low energy flux within the field of view of our telescopes would have been undetectable, and at high energies the source was not detected in either of the two experiments. The existence of such an extended source seems very unlikely, however, in view of the optical morphology of the region: η Carinae is embedded in Herschel's 'Keyhole Nebula' NGC3372, and there is no evidence for any extended supernova remnant. The third possibility also seems very unlikely if the X rays come either from a shock region outside the $10''$ visible shell or from the volume inside the shell. We can see no observational evidence for any variable source with a time scale of the order of 1 min over 40 min of observation; a source as strong as that found by the Livermore group¹⁹ would have been observed in a few minutes.

We shall therefore assume that the first hypothesis is correct. The present upper limit on soft X-ray emission then removes the problem encountered by Davidson and Ostriker²⁰ of a high ambient density around the object, and it also removes any basis for expecting coronal lines in the visible spectrum. The pulsar model, already unlikely on the basis of the Livermore observation²⁰, now seems even more unlikely, because the total X-ray luminosity which, on the basis of Ostriker and Gunn's model⁷, should exceed that of the Crab Nebula ($\sim 10^{38}$ erg s⁻¹ above 1 keV), is at least three orders of magnitude lower. On the Compton model¹⁸, the predicted flux density in the neighbourhood of a few keV is of the order of 10^{-28} erg cm⁻² s⁻¹ Hz⁻¹ for the 'most likely' model with relativistic electrons with a low energy cut off at $\gamma = 10^3$ and a magnetic field of about 10^{-3} gauss, but it can be very much less if the cutoff energy is greater. The corresponding upper limit from our observations (averaging 1.5–7.5 keV) is 4×10^{-29} erg cm⁻² s⁻¹ Hz⁻¹, which could be taken as indicating a higher low energy cutoff on this model.

The balance of the evidence, however, reinforced by the failure to detect any X rays, favours strongly the view that the spectrum of η Carinae is of thermal origin, with the bulk of the energy coming out from dust grains.

We thank A. D. Thackeray and P. R. Warren for supplying a spectral tracing of η Carinae, and P. G. Murdin for discussion.

Radio emission from Hen1044

CONTINUUM radio emission has been detected from several early-type emission-line objects which show a strong infrared excess^{1–9}. Here we report the detection of radio emission from a Southern Hemisphere compact emission-line object Hen1044 (He2-113).

Observations were made at 3.0 and 6.0 cm using the CSIRO 64-m telescope at Parkes, which has half-power beamwidths of $2'.5$ and $4'.0$ at these two wavelengths. At both wavelengths beam-switching was used to reduce atmospheric effects, the beam separations being 6.2 and 2.8 half-power beamwidths respectively. At 3.0 cm (9.86 GHz) a mixer receiver¹⁰ was used with a predetection bandwidth of 500 MHz and a system noise temperature of 650 K. At 6.0 cm (5.0 GHz) a cryogenically cooled parametric amplifier was used with a predetection bandwidth of 300 MHz and a system noise temperature of 80 K. An on-on source technique of observing similar to that described previously⁴ was used, except that here the two beams were separated in azimuth.

Radio emission was detected from Hen1044 at both 3.0 and 6 cm wavelengths. The flux density determined from 10 independent measurements made during the period 1973 August 24 to 27 was 0.24 ± 0.03 Jy at 3 cm. Observations at a wavelength of 6.0 cm were made during the period 1973 October 17 to 22. Two independent measurements yielded a flux density of 0.11 ± 0.03 Jy. Scanning observations were also made at this wavelength. The means of five right ascension scans and 11 declination scans are shown in Fig. 1. The radio source is unresolved and the region is reasonably free of confusion. The differences between the

Fig. 1 Declination and right ascension scans of Hen1044 at 6 cm; the epoch for both coordinates is 1950.

optical position (RA 14 h 56.3 min dec. $-54^{\circ}06'$, epoch 1950) and the radio position are 4 s in right ascension ($36''$ on the sky) and $20''$ in declination. These differences are within the pointing errors of the telescope.

The object Hen1044 has a stellar appearance¹¹, with "no obvious surrounding nebulosity"¹². Its optical spectrum, which has shown no appreciable change between 1962 and 1973 (refs 12,13), is that of a low-excitation planetary nebula associated with a cool WC star. The object is one of only four which have been classified¹² as WC 10. Continuing mass outflow is indicated by the presence of P Cygni profiles. These characteristics are suggestive of an embryonic planetary nebula. Hen1044 is very similar to the WC 9 object HD167362, from which radio emission has recently been detected^{5,14}.

The continuum radio spectrum of Hen1044 is not well defined by the two flux density measurements reported here. But if it is assumed that the radio emission did not vary significantly between the two dates, and that the emission is produced by the bremsstrahlung mechanism, then the emitting region has an optical depth of 1 at ~ 8 GHz, indicating an emission measure of $\sim 10^8 \text{ cm}^{-6} \text{ pc}$. If the radio emission is associated with circumstellar gas at a temperature $\sim 10^4 \text{ K}$, then the angular size of the radio source is $\sim 1''$, consistent with the upper limit to the optical size. Very similar results have been found¹⁴ for the bright central component of HD167362.

marily from extragalactic sources. In an intermediate group there are those³ who think that perhaps only the most energetic particles ($E > 10^{18} \text{ eV}$) are derived from extragalactic sources.

The observation^{4,5} of cosmic γ rays has given hope for a distinction between the Galactic and extragalactic models, at least for the energies of cosmic ray protons ($1 \text{ GeV} < E < 10 \text{ GeV}$ mainly) whose collisions with interstellar gas atoms are considered to give rise to the π^0 mesons from which the γ rays are derived. The experimental data, which relate to the intensity of γ rays above 100 MeV as a function of Galactic longitude, indicate rather clearly that there is an increase in the emissivity of γ rays (defined as the rate of production per unit volume) towards the Galactic centre (GC) with a peak in the region of radial distance from the GC, R , of about 5 kpc. There is some argument as to the actual variation of emissivity with R : Puger and Stecker⁶ derive a very sharp peak at $R=5$ kpc whereas one of the present authors, Strong⁷ (to be published) derives a rather more gradual variation of emissivity. Figure 1 shows

Fig. 1 The variation of γ -ray emissivity relative to that at the Sun $w(R)$, as a function of distance from the Galactic centre (R), deduced from observations by the OSO-III and SAS-II satellites. Cylindrical symmetry about the centre has been assumed in order to unfold the experimental data. The quoted errors are statistical only. — — Average emissivity for the first two bins of radial distance.

the average relative emissivity derived by the present authors using Strong's method for the longitude range 270° – 90° .

So far the interpretations have suggested that there is an increase in the flux of cosmic rays towards the GC corresponding to cosmic rays of Galactic origin. A number of models have been proposed: an increased containment time arising from an enhanced magnetic field⁷, structured acceleration in the hydrodynamic shock driven by the expanding gas in the "3 kpc arm"⁸ and, very recently, an increased yield in the spiral arms resulting from an assumed correlation between the cosmic ray flux and the neutral hydrogen density in the arms (Bignami and Fichtel⁹).

In all these models it is assumed that the predominant interaction responsible for the parent π^0 mesons is between

Relevance of cosmic gamma-rays to origin of the cosmic radiation

THE controversy over the question of the origin of energetic cosmic rays is well known. There are those who believe that the bulk of the radiation comes from Galactic sources, such as supernovae¹ and others² who find rather good reasons for supposing that the radiation comes pri-

cosmic-ray protons (with a small admixture of α particles) and the protons from neutral hydrogen atoms. The variation of atomic hydrogen density with R has been derived from 21 cm data which shows (see Mezger⁹ for example) that the average surface density of neutral hydrogen in the range $0 < R < 5$ kpc is about one half that at $R \sim 10$ kpc (the location of the Solar System). In all the calculations some allowance has been made for the presence of unseen gas, presumed to be mainly molecular hydrogen, by multiplying the predicted γ -ray yields by a factor of ~ 1.5 , this having been thought to be a 'reasonable' factor.

It has been noted before that the distribution of γ -ray emissivity appears to correlate quite well with that of giant H II regions (ref. 8 and A. W. Strong, unpublished). Now it is well known that dense ($\sim 10^3$ cm⁻³), massive ($\sim 10^4$ – $10^5 M_\odot$) molecular clouds are found in association with such H II regions¹⁰, and such clouds will be copious sources of γ rays. (The possibility that nearby clouds may be observable as point sources has in fact been suggested by J. H. Black and G. G. Fazio, unpublished). What appears not to have been realised until recently is the fact that the contribution of the molecules to the gas density at $R \sim 5$ kpc may be very large: according to Solomon¹¹ and N. Z. Scoville and P. M. Solomon (private communication), the smoothed molecular hydrogen density in the region 4–6 kpc from the Galactic centre may be as high as 10 cm⁻³, compared to a total gas density near the Sun of only about 1 atom cm⁻³. (It should be remarked that the importance of the correlation between the molecular hydrogen distribution and that of γ rays has also been stressed recently by Solomon and Stecker¹².)

As is clear from Figure 1, the increase in molecular hydrogen density is quite adequate to account for the observed γ -ray intensities with a uniform cosmic ray flux if, as would seem likely, the molecular clouds have a distribution perpendicular to the Galactic plane not too different from that of the H II regions (with a full width of about 100 pc¹³). Explanation in terms of molecular hydrogen was in fact suggested some time ago by Stecher and Stecker¹⁴, although at that time there was no direct evidence for an increase in the molecular hydrogen density towards the Galactic centre and later explanations by Stecker and coworkers have concentrated on cosmic-ray gradients such as would result from Galactic sources of the cosmic-ray protons or at least Galactic acceleration of the particles.

The importance of the new result is that the necessary constancy of the cosmic-ray flux would be more consistent with a largely extra-galactic origin of the cosmic rays rather than a Galactic one.

In conclusion, it is clear that, unless the molecular hydrogen measurements are seriously in error the γ -ray data do not now necessarily demand explanation in terms of a Galactic origin for the initiating cosmic rays.

We thank the Science Research Council for continued support and Professor P. M. Solomon for communicating unpublished information.

Formation of holes in the solar corona

SOFT X-ray spectroheliograms obtained from Skylab¹ and rocket flights² show many bright filamentary features which map out the magnetic structure of the solar corona. Additional interesting features are the extensive regions from which the emission is extremely low. These long, but relatively narrow, 'coronal holes' can stretch much of the way across the solar disk in a roughly N–S direction. The photosphere and chromosphere beneath are relatively featureless and have low magnetic flux density. The magnetic structure of these lower levels is not untypical of other quiet regions on the Sun where coronal holes have not developed. This suggests that the magnetic configuration associated with the holes might not have emerged from the solar surface with any particularly unusual geometry, but this might have developed later due to some rearrangement within the atmosphere. Changes in field structure within the corona have been regarded for more than a decade as part of the normal process of development during the solar cycle³.

The spectroheliograms indicate the existence of long magnetic-arch structures in the solar atmosphere². It is thought that these arches are produced by merging of smaller structures by cross-connection of field lines, since this results in a reduction of the magnetic energy stored³. How this proceeds depends upon the initial conditions, but the trend is illustrated by the simple case in Fig. 1a. Where the flux tubes touch their neighbours there will be merging to produce the resultant fields shown as solid curves with double arrow heads. Even when the initial conditions are more complex, as when the original arches emerge from the solar surface at different times, the trend should be the same.

Magnetic arches have a preferred alignment on the Sun⁴. In the northern hemisphere the vertical flux tubes tend to lie within NE–SW planes, while south of the equator they stretch roughly SE–NW. (Hereafter, both these directions are denoted as E–W. The description can then remain reasonably general because it is unnecessary to specify which hemisphere is being considered.) At any time the field tends to point from E to W in one hemisphere but from W to E in the other. In both cases the sense reverses between one 11 yr cycle and the next.

The situation discussed so far concerns interaction between the relatively young flux tubes developing within

Fig. 1 Each dashed curve represents a magnetic flux tube which passes from the photosphere into the solar atmosphere (presumably related to development at supergranulation). Because these arches have similar polarities they can merge to reduce the magnetic energy. *a*, The solid curves represent the resultant flux tubes; *b*, the situation when an additional flux tube crosses the region perpendicular to the plane of the paper. The resultant loops produced at the regions marked *w* will possibly be carried away³ by the flow of material at the solar surface. In *c* the horizontal flux tube shown in *b* is seen to cross two parallel arches. Curves with arrow heads illustrate how cross connection between field lines from each of the three flux tubes allows a line to pass from one transverse arch to the other.

quiet regions on the Sun. It is necessary to take into account the interaction with other arches produced earlier in the solar cycle, or even during the previous cycle. Some particularly long structures develop in roughly N-S directions. These stretch between pairs of active regions or from active regions to polar caps⁵. It is also possible that flux passes from one pole to the other³. If one of these N-S flux tubes comes into contact with the E-W arch system forming in Fig. 1*a*, merging between the perpendicular fields can proceed⁶. A section through the new system is shown in Fig. 1*b*; the plan view of this structure (Fig. 1*c*) shows how a field line from one of the transverse arches might cross to another by passing along a length of longitudinal flux tube. Cross coupling of field lines which leads to this configuration can be expected because it reduces the magnetic energy stored in the whole structure.

The situation becomes particularly interesting if some of the transverse arches have polarities opposing the others. A simple system containing a pair of arches illustrates this in Fig. 2*a*. A field line crossing between the pair now has both feet to one side of the longitudinal flux tube, so that the relaxation accompanying merging can separate it from the original structure. If cross connection between the pair of arches became complete, a cavity would be

produced in the magnetic field, as shown in Fig. 2*b*. The flux along the N-S tube gets 'eaten away' in this process.

Figure 2*b* shows the simplest situation where a pair of neighbouring antiparallel arches merge together. In practice the horizontal flux tube will cross many arches so that all the field lines from one will be unlikely to pass into a single antiparallel structure. A cavity can be produced nevertheless if the transverse arches towards one end of the N-S flux tube have one polarity, while the other end makes contact with fields of reverse polarity. A formalised representation of this appears in Fig. 3*a*. (Field lines like that in Fig. 1*c*, which cross from one arch to a parallel one on the same side of the boundary, have not been included because these do not represent a state having minimum energy. Such lines continue to interact with flux lying N-S until antiparallel arches are linked). This is just the situation which can produce very long coronal holes if the N-S flux tube is suitably located on the solar disk. Two cases are of interest:

(a) The more obvious case is the one where the longitudinal flux tube crosses the solar equator in the manner of the 'trans equatorial arches' observed by Hansen *et al.*⁵. It has been pointed out already that E-W arches crossing this tube would change polarity across the equator. The general alignment of coronal holes in the N-S direction between hemispheres can therefore be explained in this way.

(b) A stage is likely to be reached at the transition between solar cycles when antiparallel magnetic arches form in a single hemisphere. As solar minimum approaches, polarities associated with the old 11-yr cycle are found near the equator, while reversed fields due to the developing cycle form at intermediate latitudes³. Suitable conditions seem to be developing at present since Gillespie *et al.*⁷ reported the appearance of new cycle polarity configurations during August 1973.

Fig. 2 *a*, is similar to Fig. 1*c*, except that the fields along the transverse arches are now antiparallel. A field line crossing from one of these to the other should relax, in the direction of the double-headed arrows, from the position shown. *b*, The extreme case when all the field lines from one arch pass into the other.

At the stage when the old and new 11-yr cycles are both active, the polarities of arches will change between zones as indicated in Fig. 3b.

In addition to the coronal holes, soft X-ray spectroheliograms show regions of low emission which form along the path of dark filaments (prominences) observed in H α spectroheliograms. One of these filament cavities is labelled in Fig 1 of ref. 1, while several good examples (one of which is Y-shaped) are seen as long thin dark features in Fig. 1 of ref. 2. Such structures could be closely related to coronal holes since there is evidence that dark filaments might have the magnetic configuration drawn in Fig. 1c. It has been suggested³ that condensed material is embedded in a longitudinal field produced by local

Fig. 3 The situation shown in Fig. 2 is unlikely because it assumes that all field lines pass from one arch to a second neighbouring structure. It is far more probable that there would be interaction between numerous arches crossed by the horizontal flux tube. This could still lead to the formation of a cavity, however, if the transverse arches had different polarities on each side of a boundary. *a*, A formalised representation of how field lines from one or more transverse arches on one side of the boundary can pass into one or more structures of reversed polarity on the other side. *b* shows a number of boundaries on the solar disk across which changes in polarities of arches are likely to occur. The arrows show field directions at one stage during a 22-yr cycle. Regions denoted by *A* have fields associated with the first half of this cycle while regions *B* have polarities of the second half-cycle.

shearing of transverse support arches. Even if such structures are not formed by the exact sequence of events described here, it is still possible that a reversal in the polarity of the support arches along the length would lead to the formation of a cavity.

In the model outlined the flux tubes need only merge on a time scale of the order of one day, over which period changes in the structure of coronal holes occur. Such a rate of merging appears acceptable on theoretical grounds although, as Sweet⁹ points out, it is difficult to explain the far more rapid changes needed to account for solar flares.

I thank Professor R. L. F. Boyd and members of his group for help.

Ionospheric effects of the Flixborough explosion

ON June 1, 1974, an explosion of unprecedented magnitude occurred at the Nypro plant at Flixborough, Lincolnshire. A considerable blast wave was produced and evidence is presented here to show that this wave penetrated the atmosphere to ionospheric heights. Our purpose is to report these major ionospheric disturbances since they may yield information regarding the time sequence of the explosion and the amplitude of the blast wave that it created.

Naturally occurring waves in the ionosphere have been studied at Leicester using the high frequency (HF) radio Doppler sounding technique¹. In this method an HF radiowave is reflected from the ionosphere at steep incidence and the frequency of the received signal is monitored². Acoustic-gravity waves propagating through the atmosphere displace the reflection point and a Doppler frequency shift is produced in the reflected signal. The magnitude of the Doppler shift Δf is proportional to the rate of change of phase path of the radiowave according to the expression

$$\Delta f = -(f/c)/(dP/dt) \quad (1)$$

where f is the radiowave frequency and c is the velocity of light. If three spaced reflection points are available then the speed and direction of the disturbance may be determined from the time delays in the Doppler frequency changes observed on the three transmissions.

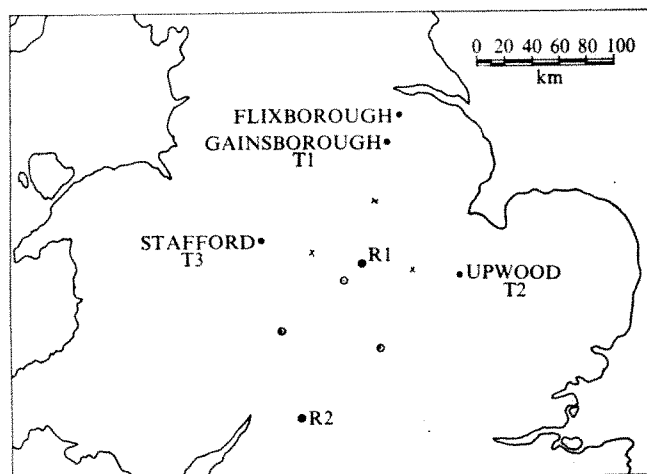

Fig. 1 Location of transmitters and receivers of the Doppler sounding system. T, Transmitter; x and o, propagation path mid points; R, receiver.

On June 1 three transmitters located at Gainsborough, Upwood and Stafford were operational. These were received at two sites, one at Leicester (R1) and one in Wiltshire (R2). Figure 1 shows the locations of the transmitters and receivers together with those of the six reflection points.

At 1600.20 GMT a major disturbance was noted on the Gainsborough-Leicester path and subsequently on the more

southerly transmissions. Recordings of frequency as a function of time were obtained from the two receivers R1 and R2 and the Leicester record is reproduced in Fig. 2. The frequencies of the three transmitters are offset by 3 Hz relative to each other so that they may be distinguished on the frequency-time recording. The principal feature on all six transmissions is the large quasisinusoidal oscillation starting at 1601.11 GMT on the transmission closest to the explosion (Gainsborough-Leicester). The feature approximates to two cycles of a sinusoidal oscillation with a period of about 50 s. The initial positive Doppler shift indicates that the electron-density

Fig. 2 Time variation of Doppler frequency shifts recorded by the Leicester receiver (R1) showing large-scale disturbances between 1600.20 and 1603.38 GMT.

is first enhanced, thus producing a lowering of the reflection level. This is followed by a negative Doppler shift indicating that the height increases rapidly. During the next half cycle the frequency shift is again positive showing a further period of decreasing height. Finally there is a very small negative Doppler shift as the height returns to its undisturbed position. The maximum Doppler frequency shift is 4.5 Hz which corresponds to a rate of change

Fig. 3 Phase height changes produced by the disturbances, calculated from the Leicester observations. Time measured from the start of each disturbance. a, Stafford; b, Gainsborough; c, Upwood.

of 142 m s^{-1} in the reflection height. This frequency deviation is a factor of four greater than those produced by naturally occurring travelling disturbances in the ionosphere. An interesting feature of the Leicester recordings are the two precursors, marked P1 and P2 in Fig. 2, which precede the main event on all three transmissions. These features are less well defined

on the recordings obtained from R2.

The velocity c of an acoustic wave in the atmosphere is given by

$$c^2 = \gamma g H \quad (2)$$

where γ is the ratio of the specific heat of the gas at constant pressure to that at constant volume, g is the acceleration due to gravity, and H is the scale height of the atmosphere at the height considered. Using the CIRA reference atmosphere³ and equation 2, the time taken for an acoustic wave to travel from Flixborough to the reflection point of the Gainsborough transmission was found to be 10.6 min. The recording in Fig. 2 shows that the major disturbance started at 1601.11 GMT and so the time of the explosion is 1550.35 GMT. This is in fair agreement with the time of 1554 GMT reported in the national press. The presence of the two precursor events P1 and P2 is not yet understood but they clearly indicate that two distinct disturbances were produced in advance of the main event. This could result from two pressure waves separated by about 40 s at ionospheric heights.

The magnitudes of the disturbances recorded by R1 (Fig. 2) are greater than those obtained at R2. The increased amplitude of the disturbances probably results from the slightly greater reflection heights of the signals received at Leicester. The amplitude of the acoustic wave will increase exponentially with height, consequently the disturbance will be greater the higher the reflection point in the ionosphere.

The phase height change (h) produced by the passage of the disturbance has been determined by integrating the frequency-time recording since from equation 1

$$h = P/2 = - (c/f) \int \Delta f \cdot dt \quad (3)$$

The height changes for the various transmissions are shown in Fig. 3. The maximum displacement is about 1.5 km and the period of the wave is about 75 s. This corresponds to a quasi wavelength of 68 km assuming the velocity of sound to be 900 ms^{-1} at the reflection height.

A detailed analysis will be undertaken to determine the exact time of detonation and to estimate the magnitude of the pressure wave at its origin. The presence of the precursor events will be examined and the significance of the double feature investigated.

The turbulent boundary layer on the continental shelf

IN the late summer of 1973 we made measurements of the current structure in the thermal boundary layer on the continental shelf. The measurements were taken under conditions of complete neutrality, well away from the influence of local

coastlines. Figure 1 shows the positions of two moorings, 001 ($48^{\circ} 10.5'N$, $07^{\circ} 54'W$), and 002 ($48^{\circ} 16.5'N$, $07^{\circ} 47'W$) separated by 15 km. This compares with a tidal excursion of about 10 km for the surface water. Both moorings were in 180 m of water and more than 200 km from the nearest mainland. The current meters were supported by subsurface buoyancy. The thermal structure of the water column, and the depths at which current meter observations were made in relation to the thermal boundary layer is shown in Fig. 2. The temperature of the bottom 100 m of the water column increases with depth. This marginal increase of temperature at the adiabatic rate ($1.3 \times 10^{-6}^{\circ}C\ cm^{-1}$) is expected of a turbulent boundary layer, because the production of turbulent energy is much greater than the stabilising effect of the buoyancy flux. The absolute accuracy is only $0.02^{\circ}C$, using a mercury-in-glass reversing thermometer as the calibration standard. The resolution is, however, considered quite genuine to $\pm 0.0005^{\circ}C$ (ref. 1).

All but one of the current meters gathered reliable current data during the same seven day period. The meter which was placed 30 m off the bottom, failed after only two days and is excluded from the analysis. For the short period that it was in operation, however, it was consistent with the measurements obtained at a slightly shallower depth, 33.5 m off the bottom. The data reduction was identical for all of the current meter records.

Fig. 1 Positions of moorings (●). Depth contours at 30 m, 200 m, 1,000 m and 2,000 m.

Kinetic energy density spectra for the current records were obtained from 2,048 two inch data points which were sampled every five minutes using a fast Fourier algorithm for complex numbers. Spectra for the current meter records obtained from mooring 001 are shown in Fig. 3. The kinetic energy density is generally less for the current meter records closest to the bottom but is evenly distributed throughout the frequency range except at the highest frequencies. The variance at the high frequencies is greatest on the record furthest from the bottom, which may be because of internal waves travelling along the thermocline. These results were also obtained for mooring 002.

Of the total kinetic energy, 80% is contained between the spectral estimates 11.4^{-1} and 13.2^{-1} cycles per hour, centred on 12.2^{-1} cycles per hour. This represents the bulk of the tidal stream energy. We have chosen this estimate to represent the motion because it represents about 90% of the mean speed.

Fig. 2 Thermal structure of the water column in the turbulent boundary layer obtained from a typical temperature profile showing the depths at which current meters were fixed in this layer (●).

To avoid a time varying analysis the kinetic energy density spectra for each record was split into clockwise and anticlockwise spectral estimates. An example of this is shown for the bottom current meter record of mooring 001 (Fig. 3). The vector addition of clockwise and anticlockwise components produces a series of ellipses.

Table 1 summarises the results obtained for the semidiurnal estimate of all the records. At semidiurnal periods 94% of the kinetic energy is contained in the clockwise motion. Table 1 also shows the semimajor (a) and semiminor (b) axes of the tidal ellipse and the ratio $-b/a$. These show that the tidal ellipses are geometrically similar but become reduced in scale as the bottom is approached; a semimajor axis of $\sim 55\ cm\ s^{-1}$ 100 m from the bottom drops to $\sim 32\ cm\ s^{-1}$ 2 m from the bottom. The ellipses are orientated such that their major axes lie roughly parallel with a line drawn through the two mooring positions. A clear difference in orientation exists between the records from different moorings, with mooring 002 rotated about 8° clockwise with respect to mooring 001. The mean phase differences, which are relative to the lower current meter on mooring 001, are less than 3° apart in the bottom 33.5 m of the water column. That is approaching the limits of the absolute accuracy obtainable using different meters. The uppermost current meter on both mooring is, however, lagging about 13° (anticlockwise) behind the lower meters. Mooring 001 as a whole, lags behind mooring 002. That is confirmed by a simple overlay of direction records.

Figure 4 summarises the distribution of clockwise tidal amplitude [$u(-)$] with respect to depth (Z). The logarithmic depth (m) above the bottom is plotted against the clockwise semidiurnal speed ($cm\ s^{-1}$). This plot has been chosen to admit

Table 1 Current meter results

possible inferences with turbulent boundary layer theory.

In the plot of Fig. 4 the data fits the form

$$u(-)/u_*(-) = (1/k) \log_e Z/Z_0$$

where $k=0.4$, $u_*(-)=1.2$ cm s⁻¹, and $Z_0=3 \times 10^{-4}$ m, for $Z < 33.5$ m.

Such logarithmic plots can, however, be matched with power laws for selected ranges, and the data could have equally been put in the form

$$Z/Z_1 = (u)/(u_1)^n$$

where $n=8$, and at $Z_1=1$ m, $u_1=24$ cm s⁻¹.

Fig. 3 Kinetic energy density spectra for records obtained on mooring 001. The total kinetic energy density has been split into anticlockwise and clockwise estimates for the current meter nearest the bottom: a, total density; b, anticlockwise; c, clockwise.

Identification of the logarithmic form with a boundary layer, where $u_*(-)$ represents the friction velocity and Z_0 the characteristic length scale relating to the boundary roughness, requires some independent confirmation. Such a form is strictly applicable only to an unaccelerated, one-dimensional flow under negligibly small pressure gradient. In a tidal stream, however, the flow is accelerated and pressure gradient forces, geostrophic forces and centrifugal forces are important. Applicability of the logarithmic form in the unsampled lower two metres may be extended through measurements in the coastal waters of Red Wharf Bay, although we have no values of current direction here². The homogeneous nature of the temperature in the bottom mixed layer suggests that eddy viscosity is related to distance from the boundary.

Two lines have been drawn in Fig. 4 as the values come from different moorings and both suggest that the flow is hydrodynamically rough (the bottom surface is sand and broken and abraded shells). The uppermost records clearly do not fit this logarithmic form and they are undoubtedly influenced by the thermocline and the boundary at the sea surface. Temperature measurements made from the upper two metres showed that the thermocline descended semi-diurnally below the uppermost current meter. This effect was

mainly responsible for the phase lag of the uppermost meter on each mooring. Continuous temperature records obtained from the other current meters showed no vertical temperature differences within instrumental resolution (0.03° C) during the complete seven day period, and this confirms the view that Fig. 2 represents a very persistent state of neutrality within 30 m of the bottom on the continental shelf.

The friction velocity of the anticlockwise component, $u_*(+)$ can be determined from Table 1, which shows that the anticlockwise energy is only ~ 7% of the semidiurnal energy on the records below 33.5 m. This gives $u_*(+)=0.3$ cm s⁻¹. The time varying friction velocity is found by adding:

$$u_*(t) = u_*(-) \exp(-i\omega t) + u_*(+) \exp(i\omega t)$$

where ω is the angular velocity (rad s⁻¹) of the semidiurnal

Fig. 4 The logarithmic profile for the clockwise semidiurnal motion.

tide. The friction velocity then varies between 0.9–1.5 cm s⁻¹. Our observations extend from spring to neap tides and so the values of $u_*(t)$ and Z_0 describe an approximate mean situation for the turbulent boundary layer of the continental shelf.

Empirical relationship for the critical temperature of some A15 superconductors

A NEW, empirical relationship¹, which links the T_c of A15 superconductors—based on the A_3B stoichiometric ratio—with the atomic mass, M_B , of the B element, indicated that $\log T_c$ is a linear function of $\log M_B$ and that high T_c values can be predicted if M_B is small. A B element is from group IVB (Si, Ge and Sn) and an A element is from group VA (V, Nb and Ta).

The subsequent discovery that stoichiometric Nb_3Ge has the highest known T_c —23.2 K (ref. 2)—provides an opportunity to test further the $\log T_c$: $\log M_B$ relationship. The original prediction for Nb_3Ge was 29–30 K (ref. 1). If the experimental value, 23.2 K, is accepted as correct then the $\log T_c$: $\log M_B$ plot, using the additional data in Table 1, defines for the Nb and Ta series, two accurately parallel lines, with a slope of $-\frac{1}{2}$.

Table 1 Transition temperatures (experimental) of some A15 compounds

	V*	Nb*	Ta*
Si†	17.1(4)‡	Not known	Not known
Ge†	7 (3)	23.2(2)	8 (16)
Sn†	4.3(3)	18.3(17)	6.4(18)

* A elements.

† B elements.

‡ Reference numbers are in brackets.

The deviation of the V alloys from this sequence occurs because some of the T_c data refer not to the stoichiometric A_3B ratio (without which accurate comparisons between systems cannot be made) but to non-stoichiometric compounds with a V content greater than 75 atm. % (ref. 3). Thus, although V_3Si is well characterised at 17.1 K for stoichiometric single phase ordered samples (refs 4 and 5, and B. A. Hatt, unpublished) the compositions of the equilibrium A15 phases in V-Ge and V-Sn are $V_{7.7}Ge_{2.3}$ (ref. 3) and about $V_{8.0}Sn_{2.0}$ (refs 3 and 6), respectively. In both cases additional experimental work would be needed on the metastable, stoichiometric A15 compounds to establish their T_c values, which would

Fig. 1 $\log T_c$ against $\log M_B$ for binary A15 compounds of group VA and group IVB elements, where T_c is the superconducting critical temperature, and M_B is the atomic mass of the IVB element. Lines of slope of $-\frac{1}{2}$ are drawn through the points for the Nb and Ta compounds. The dotted line is drawn with a slope of $-\frac{1}{2}$ through the point for V_3Si .

certainly be higher than those quoted in Table 1. At present it must suffice to use the single point for V_3Si in order to define a dashed line, with a slope of $-\frac{1}{2}$, (Fig. 1), from which the predicted T_c values for V_3Ge and V_3Sn are 10.3 K and 8.3 K, respectively. These are reasonable estimates in the light of what is known of the effect of non-stoichiometry in other systems such

as V_3Si and V_3Ga (refs 4 and 7), and the extrapolation of data³ on V_3Ga – V_3Ge pseudobinary alloys yields a T_c of 10 K for stoichiometric V_3Ge .

Accepting the data used in Fig. 1 it emerges that T_c can be expressed as a function of M_B^{-1} and that when presented in

Table 2 Slope, C , of lines in Fig. 2

C (K $u^{1/2}$)	Group VA element
90	V
198	Nb
69	Ta

this way (Fig. 2) the experimental plots for the Nb and Ta series extrapolate accurately to zero.

From Fig. 2 the transition temperature is expressed in the form $T_c = C/M^{\frac{1}{2}}$. The slope, C , for the three curves is given in Table 2. The relationship does not apply when the B element in A_3B comes from Group IIIB or the transition metals. It remains true, however, that when selected systems are compared, the Nb compound always has the higher T_c (for example, Nb_3Ga —20.3 K, and V_3Ga —15 K; Nb_3Al —18.9 K, and V_3Al —~9 K; Nb_3Au —11 K, and V_3Au —3.5 K

Fig. 2 T_c against $M_B^{-1/2}$ for the compounds shown in Fig. 1. T_c values for V_3Ge and V_3Sn are those estimated for the stoichiometric compounds from the dotted line in Fig. 1.

It is interesting to try to relate the values of C to those of some property of V, Nb and Ta (Table 3). The only property which varies in the same relative order as C , is the critical temperature, T_c (Table 3). C for the compound series has been plotted against T_c for the corresponding element (Fig. 3). A straight line can be drawn through the points. From Figs 2 and 3 it seems that, for an A15 compound A_3B , where A is either V, Nb, or Ta, and B is one of the group IVB elements Si, Ge and Sn, the superconducting critical temperature is given by:

$$T_c = 27.5 (T_A - 2) M_B^{-1}$$

where T_A is the critical temperature of pure A and M_B is the atomic mass of element B.

The existence of this empirical relationship raises three questions: first, what is its physical significance; second, why does it hold only for group IV elements; third, how far can it be used to predict higher critical temperatures?

The theory of Bardeen, Cooper and Schrieffer (BCS) gives

Table 3 Properties of elemented V, Nb, Ta to be compared with C (Table 2)

* θ_D , Debye temperature; T_c , superconducting critical temperature; γ , electronic specific heat coefficient; V_{ph} , electron-phonon interaction parameter (data from ref. 8); T_m , melting point; K , bulk modulus (compressibility); Y , Young's modulus (data from ref. 9).

the critical temperature of a superconductor as

$$T_c = (1.14h/k) \langle \omega \rangle \exp(-1/N(o)V)$$

If it can be assumed that $N(o)V$ does not vary much among the compounds under discussion, the isotope effect must derive from the average phonon frequency, $\langle \omega \rangle$. In a monatomic crystal, the phonon dispersion relationship involves (isotope mass) $^{-1/2}$ and gives rise to the classical isotope effect in some pure metal superconductors. In a polyatomic crystal the dispersion relationship has more than one branch, each of which depends upon some average of isotopic masses, usually of the form $(\sum_i 1/M_i)^{1/2}$. At the zone boundary, however, the relationship for each branch reduces to a form which involves only one of the masses, that is $\omega \propto (1/M)^{1/2}$. Thus, the quoted empirical formula for T_c is rationalised if it can be assumed that the phonon modes involved in the BCS interaction are those close to the zone boundary. This has interesting implications

Fig. 3 The slope C , of the lines in Fig. 2, against T_A , the critical temperature of the group VA elements.

for the theory of superconductivity in these compounds. The fact that the important modes are those relating to the B atoms may also explain why, in the ternary compound $Nb_3(AIGe)$, an ordering of the Al and Ge atoms is thought to be necessary to achieve maximum T_c (refs 10 and 11); disorder on the B-atom sites possibly disturbing these modes.

The similarity between elements in group IVB, both chemically and physically, is marked most strongly. They all have the same low temperature equilibrium crystal structure, and electrically are all semiconductors. This is not true of the group IIIB elements, and probably explains why a simple T_c relationship exists for compounds with IVB elements, but not for compounds with IIIB elements in which $N(o)V$ may no longer be a constant. The situation is more complicated when the second element is a transition metal, and the value of T_c depends on the position of the transition metal's d band relative to the Fermi level of the compound³.

Extrapolation of the Nb line in Fig. 2 suggests that if Nb_3Si crystallises in the A15 structure, it should have $T_c \approx 38\ K$, which would make it by far the highest T_c superconductor, with distinct economical advantages. It does not exist in equilibrium because the silicon atom radius is too small; the ratio of the radii of the two component atoms must lie between 0.85 and 1.15 in order for a stable A15 structure to form¹². An ordered (Cu_3Au) structure for this composition, with $T_c = 1.5\ K$, has been reported¹³. Codeposition of the evaporated elements onto a heated substrate has produced a non-stoichiometric A15 phase, with a maximum T_c of 9.3 K at a composition of 21 atom % Si (ref. 14). More recent attempts to form Nb_3Si under high pressures have been unsuccessful¹⁵. It may be possible to get some enhancement of T_c in a ternary compound $Nb_3(GeSi)$. The Ge-Si ratio should be such as to permit ordering on their sub-lattice, but the fraction of silicon atoms should not be so large that a weighted average radius differs by much more than 15% from the radius of the Nb atom. The compound $Nb_3(Ge_{0.75}Si_{0.25})$ fulfils these conditions, and if a weighted average of the Ge and Si atomic masses is appropriate, and if it forms a stable A15 compound, it should have a critical temperature of 25.2 K.

We thank P. M. Lee and A. J. Cottingham of the Theoretical Physics Division, Lancaster University, for discussion.

An interfacial isotope effect

RADIOACTIVE carbon is utilised commonly to tag compounds used in interfacial studies. As is usual in studies with isotopes of carbon, it has been assumed tacitly that the radioactive surfactant behaves exactly like the untagged or inactive compound. During a study¹ of condensed monolayers at the water-air interface, however, a significant kinetic isotope effect was observed in their stability behaviour.

Stearic-1-¹⁴C acid (Dhom Products), which has a specific activity of 58 mCi mmol⁻¹, was mixed with inactive stearic acid to yield a 14.3 mCi mmol⁻¹ mixture with 23.1% ¹⁴C-labelled carboxyl groups. This particular stearic-1-¹⁴C acid sample was selected because, in addition to its purity (99.5% C₁₈, 0.2% C₂₀, and 0.3% C₂₂ saturated acids), its surface pressure-area isotherm (Fig. 1) is almost identical

Fig. 1 The surface pressure-area isotherms of stearic acid monolayers on pH 2.00 subsolutions (corrected to have the same area at 30 mN m⁻¹ as inactive stearic acid). a, Inactive stearic acid; b, stearic-1-¹⁴C acid; ¹⁴C-labelled stearic acid. Compression rate=1.5 Å² molecule⁻¹ min⁻¹; temperature, 20.7° C.

to that of the highly purified inactive stearic acid (99.6% C₁₈, 0.2% C₂₀, and 0.2% C₂₂). Stearic acid was deposited from purified hexane spreading solutions on to either calcium free or 10⁻⁴ M CaCl₂ (ultrapure) subsolutions prepared from triply distilled water to which HCl, KHCO₃, or 10⁻³ M KHCO₃ and KOH of AR quality were added to vary the pH of the subsolution. The monolayers were compressed to a surface pressure of 31 mN m⁻¹ with an automatically recording Langmuir-type film balance designed for constant pressure operation. An indication of the monolayer stability was obtained by determining the decrease in the film area as a function of time, at constant surface pressure.

The measurements of monolayer stability in surface films of condensed stearic acid at pH 2.0 and 6.0, are shown in Fig. 2. The stability measurements of Ca-H-St monolayers (stearic acid monolayers on subsolutions containing calcium) were compared at intervals of 15 min and plotted (Fig. 3) as a function of the pH of the subsolution. The large decrease in the film area of inactive unionised

stearic acid films (Figs 2 and 3) result from a slow process of monolayer collapse in which crystals of stearic acid form slowly at the water-air interface. (The stearic acid and Ca-H-St monolayers consist principally of unionised stearic acid molecules below subsolution pH values of 5.5 and 4.2, respectively. The slow collapse of the monolayer is different from the catastrophic collapse observed by a number of other investigators.) Figure 2 also shows that the ¹⁴C-labelled stearic acid monolayer is more stable than the corresponding inactive monolayer. This result is not expected because the isotopic substitution occurs at an atom which is not immediately involved in the bonds that break and form as the fatty acid molecules transfer from the monolayer state to the collapsed bulk phase. This significant difference in the behaviour of the monolayer stability is attributed to a secondary kinetic isotope effect. The rate of change of the film area decrease and the isotope effect (¹²C/¹⁴C) both become greater with increasing time of compression. Figure 3 also shows that there is a difference in the stability behaviour between inactive monolayers and ¹⁴C-labelled Ca-H-St monolayers. At pH < 5.0, where the molecules are dominantly unionised stearic acid, the radioactive Ca-H-St monolayer is more stable; both monolayers possess the same stability in the pH range 5.0-7.8; and then above pH 7.8 a reversal in stability occurs with the inactive Ca-H-St monolayer becoming much more stable.

Several considerations indicate strongly that the observed stability differences do not arise from impurities in the

Fig. 2 Stability measurements of stearic acid monolayers at 31 mN m⁻¹. ○●, pH=2.0; △▲, pH=6.0; ●▲, inactive; ○△, ¹⁴C-labelled. Temperature, 20.5° C.

system. The high purity of the stearic acid samples minimises the effect of chemical impurities; and impurities arising from radiolysis would be expected to decrease the stability of the Ca-H-St monolayer throughout the pH range, not just on alkaline subsolutions. Furthermore, the peculiar stability behaviour of the ¹⁴C-labelled Ca-H-St monolayer, which rises to a maximum and then decreases again with increasing alkalinity, and the magnitude of the stability differences seem to rule out the impurity explanation.

The stability increase of ¹⁴C-labelled unionised stearic acid monolayers arises apparently from increased intermolecular forces of attraction between the carboxyl head groups and/or between the carboxyl groups and the water molecules of the subsolution. An increase in the carboxyl-group interactions is not, however, the sole effect of the isotopic substitution, because the stability of ¹⁴C-labelled Ca-H-St monolayers on alkaline subsolutions is not in-

creased similarly. Isotopic substitution of ^{14}C shifts the $\text{C}=\text{O}$ stretching fundamental from 1,715 to 1,637 cm^{-1} because of the difference in isotopic mass². The zero-point energy of the $^{14}\text{C}=\text{O}$ bond is thus lower than that of the $^{12}\text{C}=\text{O}$ bond, and the dipole moments of the two isotopic modifications of the $\text{C}=\text{O}$ bond will be slightly different because of vibrational anharmonicity. Because the dipole moment increases in deuterium substituted molecules³, it is assumed that ^{14}C -isotopic substitution also increases the dipole moment. Consequently, there should be an increase in the hydrogen-bond energy between the carbonyl oxygen atoms of the head groups and the hydrogen atoms of the water molecules and, as observed, an increase in the stability of the monolayer. The stabilising influence of the carboxyl ^{14}C atom seems to have its origin in the hydrogen bonding or dipole-dipole interactions between the carboxyl head groups and the subsolution water molecules.

Fig. 3 Comparison of the stabilities of Ca-H-St monolayers at 31 mN m^{-1} , with compression time of 15 min at a temperature of 20.6° C. ●, inactive; ○, active.

The sudden decrease in the stability of ^{14}C -labelled Ca-H-St monolayers above pH 7.8 corresponds to a significant increase in the rate of monolayer collapse¹. Apparently the isotopic substitution affects the charge distribution within the calcium stearate surface micelles so that the molecular interactions between the coordination complexes and the subsolution water molecules are weaker than they are in the presence of untagged carbon atoms (R. D. Neuman, unpublished).

It is conceivable that compounds with a high specific activity, which exist in the highly oriented arrays of the two-dimensional state, may exhibit effects not observed commonly in bulk systems. The observed kinetic isotope effect indicates that the presence of tagged atoms in the head groups of surface active agents may significantly influence interfacial phenomena. Unfortunately, this interfacial isotope effect is not understood completely and needs further clarification.

Geographic and temporal development of plagues

ALTHOUGH deterministic and stochastic descriptions of localised epidemics abound in the literature of epidemiology and quantitative biology^{1,2}, the geographic spread of epidemics has not been analyzed in such detail. (Although in ref. 2, page 205, Bailey gives equations similar in spirit to my equation (1) they seem to lack physical significance.) Realistic mathematical models of the geotemporal development of plagues could be useful in the study of epizootics (that is, in ecology, wildlife management or veterinary medicine), of social phenomena (such as the spread of drug abuse or fads), and of history. Needless to say, such models should also be applicable to public health questions.

I report here the results of an investigation of the propagation of epidemics using a simple, but plausible, deterministic model, and compare them with Langer's data on the Black Death of 1347-50 (ref. 3). First I describe the model, then explore its mathematical properties and in particular its ability to sustain wave-like (propagating pulse) solutions, compare its predictions with existing data³, and finally discuss its shortcomings and suggest directions for further research.

To describe the progress of plagues as simply as possible, it is convenient to assume only two interacting populations which can be taken to be infectives and susceptibles, although one might equally well consider hosts and parasites (for example, rats and fleas) or humans and vectors. We can express the change with time of the number of infectives within a small area as the rate of transitions from the susceptible population, less the removal rate (defined as the mortality, plus recovery, plus the net physical outflow from the area). The temporal variation of the susceptible population can be expressed similarly, except that the transitions from susceptible to infective appear as a net loss, and that the rate of removal is merely the net outflow. It is reasonable to suppose that, under the conditions obtaining during plagues, the net outflows of the infective and susceptible populations result from random walks rather than mass migrations, and thus can be represented as simple diffusion. The resulting equations are:

$$\frac{\partial I}{\partial t} = KIS - \mu I + D \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) I \quad (1a)$$

$$\frac{\partial S}{\partial t} = -KIS + D \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) S \quad (1b)$$

where S and I are the susceptible and infective population densities, μ is the mortality rate (which for simplicity I have represented as a Poisson-distributed process) and the transition rate from I to S is proportional to the rate of binary encounters between infectives and susceptibles. The transmissibility coefficient K may be expressed in terms of more fundamental quantities:

$$K = 2 \int_0^\infty db b \int_0^\infty dv v \Phi(b, v) f(b, v) = 2 \langle bvf \rangle \quad (2)$$

where $f(b, v)$ is the infection probability as a function of distance of encounter, b , and velocity v , and $\Phi(b, v)$ is the distribution function for encounters. This K represents the average area of infection swept out by an infective per unit time, and KS is therefore the number of new infectives produced per unit time, per infective. The diffusion constant, D is assumed the same for both groups, since there is no good reason to assume it is not the same. The model represented by equations (1) and (2) is usually described as deterministic although it incorporates probabilistic ideas in three places (the rate of binary encounters, the random walks leading to a diffusion term, and the Poisson-distributed mortality) because it admits of numerically precise solutions and gives no idea of what the variance of I and S should be. (Although we should clearly expect the variances of the numbers of individuals to be found in the area dA to be roughly $I dA$ and $S dA$, respectively, by analogy with other counting experiments.)

Since we are interested primarily in the simple case in which the initial susceptible population density is uniform, $S(\vec{x}, 0) = U$, we can reduce equation (1) to dimensionless form by scaling:

$$\begin{aligned} I &\rightarrow UI \\ S &\rightarrow US \\ x &\rightarrow (D/KU)^{1/2} x \\ t &\rightarrow (KU)^{-1} t \end{aligned}$$

and so

$$\frac{\partial I}{\partial t} = IS - \lambda I + \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) I \quad (3a)$$

$$\frac{\partial S}{\partial t} = -IS + \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) S \quad (3b)$$

where $\lambda = \mu/KU$.

Langer's map, in which contours of the progress of the black Death are drawn for equally spaced time intervals (Fig. 1), strongly suggests wave-like propagation of this disease. For this reason I have investigated whether equation (3) can support propagating one-dimensional (plane) waves. Letting $I(\vec{x}, t) = I(x - vt)$ and $S(\vec{x}, t) = S(x - vt)$, we obtain the coupled, second-order ordinary differential equations

$$-vI' = IS - \lambda I + I'' \quad (4a)$$

$$-vS' = -IS + S'' \quad (4b)$$

These equations constitute a nonlinear eigenvalue problem. The interesting question is, for what values of λ will the equations have solutions satisfying the conditions

$$\begin{aligned} I(-\infty) &= I(\infty) = 0 \\ 0 \leq S(-\infty) &< S(\infty) = 1 \\ I, S, v &> 0? \end{aligned}$$

Adding equations (4a) and (4b), we find

$$\frac{d}{dx} [I(x) + S(x)] = \lambda e^{-vx} \int_{-\infty}^x e^{vx'} I(x') dx' > 0 \quad (5)$$

so that

$$I(x) + S(x) < I(\infty) + S(\infty) = 1 \quad (6)$$

On the other hand, if we integrate (4b) from $-\infty$ to $+\infty$ we obtain (note $S'(-\infty) = S'(\infty) = 0$)

$$\Delta S = S(\infty) - S(-\infty) = \frac{1}{v} \int_{-\infty}^{\infty} dx I(x) S(x) \quad (7)$$

However, integrating (4a) from $-\infty$ to $+\infty$ we find

$$\lambda \int_{-\infty}^{\infty} dx I(x) = \int_{-\infty}^{\infty} dx I(x) S(x) = v \Delta S \quad (8)$$

and since $0 < S(x) < 1$ for all x ,

$$\int_{-\infty}^{\infty} dx I(x) > \int_{-\infty}^{\infty} dx I(x) S(x) \quad (9)$$

or

$$\frac{v}{\lambda} \Delta S > v \Delta S$$

That is, wave-like solutions can only exist if

$$\lambda = \mu/kU < 1 \quad (10)$$

This criterion which the ratio of the rate constants, μ and KU , must satisfy has an obvious physical interpretation: if the infectives die too rapidly, they cannot spread the disease; whereas if the population density multiplied by the transmissibility factor K is too small, the plague cannot be transmitted either. (I should add that it is straightforward to show that outward-propagating circular waves are also solutions of equations (3); see also ref. 2, page 205.)

There are various ways one might attempt to find an approximate solution of equations (4) and thereby estimate v as a function of λ . I thought it more interesting to consider the original partial differential equation in order to see explicitly how wave-like solutions arise. I have therefore solved numerically the (one-dimensional) equations

$$\frac{\partial I}{\partial t} = IS - \lambda I + \frac{\partial^2 I}{\partial x^2} \quad (11a)$$

$$\frac{\partial S}{\partial t} = -IS + \frac{\partial^2 S}{\partial x^2} \quad (11b)$$

on a spatial mesh of 100 points. The development of and final form of the propagating solutions is essentially independent of the initial distributions $I(x, 0)$ and $S(x, 0)$, as long as they bear some resemblance to a plague locus entering a previously uninfected population of susceptibles. (When the ratio μ/KU exceeds the critical value, unity, initial perturbations rapidly die away.) A typical propagating solution is shown in Fig. 2. The (approximate) velocities of propagation, the maximum density of infectives, and surviving populations are given in Table 1 for various values of μ/KU .

At the time of the Black Death (1347 AD) the population density U of Europe was about 50 mile⁻². To try to get a rough idea of what D should be, we note that communication was such that one might expect minor news or gossip to diffuse a distance on the order of 100 miles in a year, that is $D \sim 10^4$ mile² yr⁻¹ (ref. 4). The area swept out in ambulation at a nominal 1 mile h⁻¹ slow walk, assuming $\langle fb \rangle \sim 0.5$ foot (corresponding to a 5-foot flea-hop times a 10% average transmission probability) is 0.4 mile² yr⁻¹ and so $KU \sim 20$ yr⁻¹. Assuming a mortality rate of $\mu \sim 15$ yr⁻¹ (corresponding to a 2-week infectious period) we expect a velocity of propagation of 200–400 mile yr⁻¹. This velocity is in substantial agreement with that which can be estimated from Fig. 1. (All the numbers given above were educated guesses, but the resulting speed is insensitive to their values since $v \sim \sqrt{KUD}$. My object in making these guesses was primarily to indicate the reasonableness of the model and its predictions.)

The results reported here can be summarised as follows. The gross features of the geographical progress of epidemics can be described by means of a deterministic model which is strongly reminiscent of models which have been used to describe chemotaxis⁵, propagation of neural impulses⁶, complex organic chemical reactions^{7,8}, and the advance of advantageous genes along a one or two-dimensional habitat⁹⁻¹¹. The model presented here gives rise to propagating solutions whose velocities are (primarily for dimensional reasons) comparable with the observed velocity of the Black Death of 1347 AD when the physical constants in the model are set to reasonable values. It is particularly important that, given the infectious period of the disease (essentially the time for removal of a diseased individual from the population of infectives) and its transmissibility, K , we can estimate the

Fig. 1 Approximate chronology of the black death, 1347 to 1350. (From *The Black Death* by William L. Langer. Copyright © 1964 by Scientific American, Inc. All rights reserved.)

Fig. 2 A typical numerical solution of the (one-dimensional) equations (11a) and (11b) which shows clearly the pulse-like character of the plague after the introduction of the initial infection. The equations were solved on the spatial interval $0 < x < 100$ in unit steps and with time-steps of 0.5. The distributions of susceptibles, $S(x, t)$, are indicated by dashed lines after 60 and 80 time steps. The distributions of infectives after 20, 40, 60, and 80 time steps are indicated by the solid lines. The initial distribution of susceptibles was uniform and equal to unity, whereas that of the infectives was zero for $x > 5$, and consisted of 5 random numbers lying between 0 and 0.01, for $1 < x < 5$. Repeated runs indicate that after 20 time steps the distributions are independent of the initial ones, for a very wide range of initial infectives introduced in the vicinity of $x=0$. (Note also that the precipitous drop in $S(x, t)$ near $x=0$ is an artefact of the boundary conditions, which remains fixed in space and which does not reflect the true number of remaining susceptibles after the plague wave has passed.) $\lambda=0.5$.

critical (minimum) population density necessary for the outbreak of epidemics:

$$U > U_{crit} = \mu/K. \quad (12)$$

This relation may have some use as a historical tool, since if K and μ are known for a given type of epidemic, and if D can be estimated more accurately than was possible herein, for a given terrain and cultural level, then the local value of U can be extracted from the observed advance of plague fronts. Moreover, if we consider the maximum value of I in the wave, we see that it decreases monotonically with λ , and so gives an independent estimate of μ/KU . Finally, if we apply a reasonable model of the inheritance of susceptibility to estimate the relative frequency of susceptibles and immunes after a given period of time, starting from some initial relative frequency, and if we take into account the recurrence time for major historical epidemics of a given kind, we should be able to at least check for self consistency estimates of population and of plague severity such as those quoted by Langer³.

It is also interesting to extract from the solutions of this model the appearance of the plague wave to a stationary observer. He would see an extremely sudden onset of the

disease, during which some fraction of the susceptibles catch the disease, followed by the afflicted dying. Note that in these calculations, not all of the susceptibles become infected and die. The survivors of high-mortality plagues $\mu/KU > 0.5$ are therefore a mixture of the immune and the merely fortunate. Paradoxically, the more rapidly fatal the disease is on an individual basis, the better it is for the population. (This is, of course, well known from the theory of localised epidemics.) Because of the existence of a critical value, μ/K , of the susceptible density, we expect the actual development of a plague to follow the sequence: (1) increase of U by general population growth or in-migration past U_{crit} and thereby the creation of a substantial instability toward a plague wave; (2) introduction of the plague agent above the minimum threshold; (3) extremely rapid development of plague. The present situation of many industrialised nations is such that the density of susceptible individuals is at least a factor of 10 greater than that which obtained in mediaeval Europe. The present calculations suggest that any serious outbreak of bubonic plague, such as might be expected to follow a lengthy disruption of medical services, would result in the death of essentially all the susceptibles. What fraction of the population might be so described is not clear, especially in the face of possible mutations of the responsible microorganisms, but it probably is at least 25% and might exceed 75%.

Table 1 Parameters of plague waves for several values of the damping parameter $\lambda = \mu/KU$

μ/KU	v (in units of \sqrt{KUD})	I (max)	S_i
0.10	2.0	0.7	~ 0
0.25	1.9	0.4	~ 0.025
0.50	1.5	0.14	0.22
0.75	0.8	0.03	0.6
0.90	0.55	0.004	0.8

There are several grounds on which to criticise the present model. First, the usual density distribution of human populations is clumped, not uniform (because people tend to live in villages and cities); and second, the model takes only the most elementary account of chance. As long as we do not attempt too detailed a simulation, averaging over the clumps will doubtless give the same gross predictions as the uniform distribution. On the other hand, the major divergence of the results of the deterministic model from those of the more fundamental stochastic approach is most likely to be that the latter would also predict a minimum threshold for the number of initial cases of the disease, below which propagating solutions are improbable. (We would expect this effect because statistical fluctuations would tend to damp out a small outbreak with near certainty.)

It is worth reiterating that models such as that presented here could be applied directly to the study of epizootics and should therefore be useful in ecology, wildlife management and veterinary medicine. Further, the spread of certain mass sociopsychological phenomena (such as new religions) might be sufficiently similar to that of plagues as to be worth investigating by similar methods.

Identification and follow-up of infants at risk of sudden death in infancy

In the past 10 yr infant deaths in the age group 1 week up to 1 yr have levelled off at about 7.5 per thousand. About half these deaths are sudden and unexpected and are consequently referred to a coroner for certification; subsequent *post mortem* investigation reveals evidence of disease likely to cause death in 30% of sudden deaths: in the remainder the cause of death is obscure and such a case may be described as sudden infant death syndrome, SIDS, or more conveniently as cot death. In 1972 a panel, convened by the National Institute of Child Health and Human Development, Washington, to discuss the status of epidemiological research in SIDS considered a prospective study of high risk babies of primary importance, but doubt was expressed as to whether a sufficiently high risk group could be identified to make such a study feasible (P. Froggatt, personal communication). We report the results of the first year of such a prospective study.

To determine means of identifying high risk babies at or soon after birth, detailed obstetric and perinatal histories were abstracted for 119 cases of sudden infant death and 135 live controls born in the same hospitals¹. In this study we excluded cases of sudden infant death associated with serious congenital anomaly, for example, congenital heart defect or Down's syndrome. We intended that the high risk group should include both explained and unexplained deaths. The former group, comprising 29% of the 119 cases, are potentially preventable and their identifying characteristics were found to differ little from those of the unexplained deaths.

From univariate tabulations a set of 40 variables were selected which could be ascertained at or soon after birth and which gave some indication of being of prognostic value. Stepwise discriminant analysis showed that the variables, shown in Table 1 in order of importance, were statistically significant. The sign of the coefficient indicates whether estimated risk increases as the variable increases. For example, the risk decreases as the age of the mother increases and also if her blood group is A and if she intends to breast feed the baby. Conversely, the risk increases as the birth order of the child increases and if the blood group is O, B or AB. Using these variables Mahalanobis' generalised squared distance between the groups is 1.62 and the observed

* $0.005 > P > 0.001$. † $0.05 > P > 0.01$.

discriminant scores were approximately normally distributed. This implied that a high risk group comprising 15% of the population with the highest scores was expected to include 60% of sudden infant deaths and hence have a relative risk 8.6 times the remainder. A similar analysis by Kraus *et al.*² using linked birth and death registration data for white children in California apparently gave a generalised squared distance of 0.8 which would imply that the relative risk of the corresponding high risk group would be 4.5. Shrinkage³ may be expected to reduce the relative risks in practice.

A prospective study was set up as follows. The discriminant scores of all babies born in a defined area to be evaluated within 24 h of birth; scores larger than 85% quantile defined group A and the remainder group B. Half group A, selected at random, together with samples of group B were invited to participate in the study. This comprised an initial clinical examination made within 48 h of birth, a second at 5 weeks, together with 10 visits to the home spread over the first 20 weeks of life by specially appointed health visitors. The study started in January 1973.

During 1973, 6,003 births were screened, 19 more than the number of births registered in the area for the year. The results were as shown in Table 2. The observed relative risk for those in group A not selected for study is 6.1 which is significantly greater than 1.0, $0.005 > P$. The risk of the group who did not participate is higher and also significant. There are encouraging indications that the study may be preventing some deaths. This agrees with case reports. Hospital admission rates confirm that group A is a high risk group.

We conclude that a large scale study of all forms of post-neonatal infant mortality along these lines is feasible, and offers the best method of reducing these deaths. Meanwhile our study continues.

This study is being supported by the Foundation for the Study of Infant Death, and the Public Health Department, Sheffield.

Thegosis in herbivorous dinosaurs

The name thegosis was coined by Every and Kühne¹ for the short and powerful process of tooth sharpening which is accomplished in mammals by the grinding of one tooth against another. Thegosis produces sharp-edged, planar (or curved planar) wear surfaces on the teeth. The thegosis wear

facets cut straight across boundaries between dentine and enamel and are typically marked with deep parallel striations (not necessarily coincident with the maximum slope of the wear facet). In some mammals thegosis keeps certain teeth sharply honed for use as weapons (as with the canines of suids and hippopotamids); in others thegosis sharpens the teeth which deal with food (as with the carnassial apparatus in felids).

In mammals thegosis wear is accompanied by a second type of tooth wear, dental abrasion, which occurs at food/tooth interfaces during mastication. Areas worn by abrasion are not sharply defined and have an irregular topography which more or less follows the original form of the tooth. In abraded areas the dentine is excavated to leave the more resistant enamel as a rounded wall and there are deep and shallow scratches without preferred orientation. During mastication the thegosis wear facets suffer abrasion; eventually they need to be recut by thegosis.

Tooth sharpening is not exclusive to mammals. Some herbivorous reptiles (notably ornithischian dinosaurs) seem to have sharpened the teeth by thegosis-like grinding, in spite of the fact that there was rarely any consistent pattern of occlusion. Two types of tooth wear in ornithischians are counterparts of thegosis wear and abrasion wear in mammals. Though the thegosis wear facets of ornithischians seem to differ from those of mammals in lacking deep parallel striations, it is evident that a process of tooth sharpening which closely resembled mammalian thegosis did operate in ornithischians and in some other herbivorous reptiles. Lack of striations from the thegosis wear facets of reptiles might be explained by assuming that active thegosis was a relatively infrequent occurrence. Then, in the long intervals between episodes of tooth sharpening, any striations would have been obliterated by abrasion wear. This is exactly the system of tooth wear which Every and Kühne describe¹ in the Eocene tapiroid *Lophiodon*. Tooth sharpening in herbivorous reptiles may not have been exactly comparable with tooth sharpening in mammals (particularly in view of reptilian polyphyodonty), but the mechanisms produce such similar patterns of tooth wear that I feel justified in referring to both as thegosis.

Before examining dental abrasion and thegosis in reptiles it is necessary to mention a third type of tooth wear which occurs in some ornithischians. This is wear caused by interdental pressure (Fig. 1a). Wear facets produced by interdental pressure are sharply defined, small in area, rounded in shape, and have flat or slightly irregular surfaces. These facets of this type are developed where the teeth in juxtaposition of the tooth crown, though they may sometimes be found on the lateral or medial surface. Wear facets of this type are developed where the teeth in adjacent alveoli are in contact and they are commonest where the teeth are crowded into the jaw bones and have an overlapping arrangement¹. Wear facets produced by interdental pressure are concealed in the intact dentition and can be seen only when the teeth are separated.

Blunting of the tips, edges, denticles, cingula and wear facets of the teeth in ornithischians is evidently the product of abrasion (Fig. 1b). Comparable tooth wear is doubtless universal among reptiles.

The literature dealing with the teeth in living and fossil reptiles gives the impression that thegosis wear is best developed (or at least best documented) in the ornithischian dinosaurs. Thegosis wear (though not identified as such) definitely occurs in some other herbivorous reptiles—in sauropods³ and in certain lizards⁴—and might well be expected to occur in some of the prosauropods, therapsids and pareiasaurs. I can find no evidence that the teeth were ever sharpened by thegosis-like grinding in omnivorous and carnivorous reptiles.

Few herbivorous dinosaurs used the teeth as sabre-like slashing weapons, analogous to the canine teeth of suids,

Fig. 1 Outline sketches of ornithischian teeth to show different types of tooth wear. a, Small, rounded and sharply-defined facets produced by interdental pressure; b, ill-defined areas of abrasion wear (stippled); c, single, large and sharply-defined facet produced by thegosis; d, pair of large sharply-defined facets produced by thegosis. Loosely adapted from illustrations in Thulborn^{2,13}.

tayassuids and tragulids, but this is almost certainly the function of the caniniform tusks in heterodontosaurid ornithopods⁵. In heterodontosaurids the tusks could not have been honed by tooth-on-tooth wear⁵ and their slashing edges are finely serrated instead⁶⁻⁸. No reptiles, living or extinct, seem to have employed thegosis to maintain dental weapons in fighting trim, and I conclude that herbivorous dinosaurs used thegosis solely to sharpen the edges of those teeth which dealt with food materials.

In some ornithischians thegosis wear (or a very similar type of tooth wear) was developed on a large scale: planar wear surfaces were formed along entire sections of the cheek dentitions in heterodontosaurids⁵⁻⁸, hadrosaurs⁹, ceratopsians¹⁰⁻¹² and some protoceratopsians¹²⁻¹⁴. In most ornithischians, however, thegosis wear facets were developed on individual teeth: single or paired facets (Figs 1c, d) are found in the teeth of fabrosaurids¹⁵, hypsilophodontids^{2,12,16}, pachycephalosaurids^{13,17}, some protoceratopsians^{13,18}, iguanodontids (*sensu lato*)^{13,19-21}, psittacosaurids^{13,22}, ankylosaurs^{13,23} and stegosaurs^{13,24}. A single wear facet (Fig. 1c) indicates that the tooth was sharpened directly against a single counterpart tooth in the opposing jaw; paired wear facets (Fig. 1d) were produced when the tooth interlocked with a pair of teeth in the opposing jaw¹³. Both single and paired facets may occur in members of a single species¹³.

Recognition of thegosis (or, at least, of a process closely akin to mammalian thegosis) in herbivorous dinosaurs warrants some reconsideration of tooth function in these animals. Evidently the sharp tooth edges and the planar wear surfaces produced by thegosis played important parts in mastication. The planar wear surfaces effectively reduced the tooth crowns to wedges, and as these were driven into the food they splayed it open and, eventually, divided it into two pieces. By sharpening and re-sharpening the leading edges of the wedge-like teeth thegosis enhanced and maintained the food-cutting action of the dentition. Any grinding of food between the thegosis wear facets of opposing teeth would have been incidental to this food-cutting process. It cannot be emphasised too strongly that thegosis was not directly involved in mastication: the process of thegosis merely shaped the teeth for use as tools

in mastication. In short, the cheek teeth of many herbivorous dinosaurs might best be envisaged as chopping or cutting tools, rather than as grinders.

Echolocation of insects by horseshoe bats

MOST bats of the Suborder Microchiroptera use echolocation during the pursuit of insect prey¹. This conclusion was originally based on observation that bats emitted high frequency orientation sounds during pursuit of insects and that their repetition rate increased sharply during close pursuit manoeuvres. Experiments in controlled laboratory conditions later demonstrated that little brown bats (*Myotis lucifugus*) could capture fruit flies (*Drosophila* sp.) by echolocation when vision and passive hearing of insect flight sounds were not possible².

This does not mean, however, that all insectivorous bats necessarily employ echolocation to the exclusion of other methods for locating insect prey. Indeed, Moehres³ observed that bats were attracted by the buzzing sound of insects which were not visible and probably not detectable by echolocation. Kolb⁴ has demonstrated experimentally that the European *Myotis myotis* commonly detects non-flying insects by passive hearing. Recently, Kolb⁵ suggests that olfaction plays an important role in food location, and that pulses of high frequency sound are accompanied by air currents which stir up odours. But the data Kolb presents do not conclusively show whether the bats located the food by scent or by echolocation.

Airapetjantz and Konstantinov⁶ have recently reported that in a large outdoor flight cage horseshoe bats of the genus *Rhinolophus* used echolocation to detect only stationary insects suspended by threads. The bats seemed to cease emitting high frequency orientation sounds when a tethered moth moved its wings and made limited flights within the cage. This report is so sharply at variance with extensive observations of many species of bats in both temperate and tropical latitudes that further investigation is clearly necessary.

Although horseshoe bats have been intensively studied in the laboratory, their insect pursuit behaviour has not been observed in natural conditions with appropriate acoustic apparatus. We were able, however, to study a small colony of *Rhinolophus ferrum-equinum* which has roosted for many years in the principal buildings of the Cimiterio Suburbano in Pisa. Thanks to special permission from the municipal authorities we were able to observe and record these bats during many evenings in June 1973 as they flew out of one building and hunted insects along the pathways of the cemetery and close to the walls of several other structures.

Our portable, battery-operated apparatus consisted of plastic dielectric microphones and the amplifier-detector circuit described by McCue and Bertolini⁷. The amplified ultrasonic signals were recorded on a Pemco Model 110A instrumentation tape recorder and monitored with a small battery-operated oscilloscope (Tektronix type 323). Almost all of the horseshoe bats disappeared after the first 20–30 min of each evening's foraging flights. We could not ascertain whether they flew away from the cemetery or landed, possibly with full stomachs as is frequently the case with insectivorous bats during the summer months when food is plentiful. Most flew along a predictable flight path each evening between vertical stone walls and rows of cypress trees whose branches were about 0.5–2 m from the walls. On most evenings we placed a Holgate ultrasonic detector⁸ 20–30 m 'upstream' from the position we had selected for tape recording. The audible beat notes from this heterodyne detector alerted us as horseshoe bats approached and allowed us to concentrate attention on them rather than the numerous vespertilionid bats (probably *Pipistrellus pipistrellus*) which were also abundant in the vicinity.

While many horseshoe bats flew rapidly past our position without slowing or turning, and thus were probably not hunting, many others seemed clearly to be pursuing insects such as moths of 1 to 2 cm wingspread which were often present. On several occasions a bat would circle very rapidly around a cypress tree, flying within a few centimetres of its outer branches, and we strongly suspect that at these times they were pursuing and sometimes capturing insects that had been resting on the outer twigs. These trees were 0.5–1.5 m in diameter at the altitudes where this circling behaviour occurred.

On some evenings we attempted to elicit more insect pursuit manoeuvres within range of our microphones by presenting small tethered insects attached by light threads to a fishing pole. These were manoeuvred into the customary flight path of the bats and caused to move as nearly as possible in a normal fashion. Two or three were repeatedly attacked.

On several dozen occasions during the last two weeks of June we were able to observe flight manoeuvres that resembled insect pursuit, although it was not possible to be certain in all cases that it was an insect rather than the cypress twigs or our poles and thread that was attracting the bats' attention. Many of these were spontaneous manoeuvres when no pole or tethered insect was present while others seem directed at our tethered insects. In none of these cases was there the slightest sign that emission of orientation sounds ceased. On the contrary, their repetition rate increased as has been repeatedly observed with other insectivorous bats both in the laboratory and in natural conditions. Every time a horseshoe bat flew within reasonable range of the microphone, typical orientation sounds were emitted at characteristic repetition rates. When the bats made rapid turns, dodged our poles, or seemed interested in insects, there was always a marked increase in repetition rate.

Preliminary analysis of our tape recordings shows approximately the same physical properties of the orientation sounds as have been described for the same species dodging

wires in a relatively small laboratory room. Whenever the signal-to-noise ratio was reasonably adequate both rising and falling frequencies were distinctly visible at the beginning and end of each pulse when the output of a period meter was displayed on a cathode ray oscilloscope^{9,10}.

It seemed worthwhile to analyse in some detail pulse durations and interpulse intervals in four cases when a single horseshoe bat yielded good recordings continuously for a few seconds and during that time engaged in what seemed to be an insect pursuit. Typical pulse durations when flying reasonably straight without apparent pursuit manoeuvres were 50–75 ms, but occasional pulses had clearly defined durations as long as 85 or 90 ms. These were single pulses at reasonably high signal-to-noise ratios without any interruptions. During 'buzzes' on close approach to an insect or other small object pulse durations dropped to about 10 ms and in one case to 7–8 ms. The short series of pulses, having durations of 10–15 ms, lasted for only about 0.1–0.2 s. Interpulse intervals were almost always shorter than pulse durations, and they decreased to approximately 5 ms during the buzzes. Occasionally relatively long pulses were interrupted by intervals as short as 2 or 3 ms. Similar patterns have often been observed in the laboratory.

Thus all the greater horseshoe bats we were able to observe closely while apparently hunting insects under natural conditions emitted intense and rapidly repeated orientation sounds and gave every evidence that they were employing echolocation to locate and intercept their insect prey.

We thank Professor F. Papi and Dr E. Ferrera of the University of Pisa for hospitality and help in locating the colony. Support from the National Science Foundation is gratefully acknowledged.

Olfactory imprinting resulting from brief exposure in *Acomys cahirinus*

RECENT experimental studies of olfactory 'imprinting' in infant mammals have typically utilised relatively long term exposure to the training odour, during which that odour could become associated with such conventional reinforcers as food and warmth^{1–6}. Here we report an instance of mammalian olfactory imprinting which is truly analogous to classical avian imprinting, that is, the imprinting exposure being of a relatively short duration with no readily identifiable conventional reinforcer being present at the same time with the imprinted odour. The subject species, *Acomys*

cahirinus (spiny mouse), is a murid rodent whose precocial infants possess functional motor and sensory capabilities within hours of birth^{7,8}.

An initial experiment was conducted to ascertain whether infant *Acomys* would become attached to artificial olfactory cues associated with their cage—their home environment. As soon as a newly-born litter was discovered (about 1–12 h after birth), the parents and infants were placed together in a clean cage containing a shallow layer of bedding material overlying a level teaspoon of either ground cinnamon (Cin) or ground cumin (Cu) which had been evenly sprinkled over the bottom of the cage before the introduction of the bedding material. The animals remained in this cage in an isolation room until testing 24–26 h later—separate rooms being used for the two exposure odours. A total of 12 litters (34 young) were randomly assigned to the two exposure conditions; with seven litters (18 young) exposed to Cu, and five litters (16 young) exposed to Cin. An earlier control study had indicated that naive 1-d-old *Acomys* young show no inborn preferential response to either of the test odours.

After the 24–26 h exposure period (at 26–36 h old), the young were individually tested in a series of two-choice preference tests with Cin and Cu soiled bedding simultaneously present at opposite ends of the test cage. A young mouse was placed on a clean starting strip centred between the two areas of odourised bedding material and observed until moving entirely onto one of the areas of bedding, or until a maximum of 300 s had elapsed without a choice being made. Each young was given 10 successive two-choice preference tests in this manner.

A preference score was calculated for each subject by subtracting the number of positive responses to Cu from the number of responses to Cin. Thus, a positive score would indicate a preference for Cin over the 10 consecutive choice tests, while a negative score would indicate a preference for Cu. The 18 young that had been exposed to Cu had a mean preference score of –2.61. A Wilcoxon matched-pairs signed-ranks test on the individual preference scores indicated that the preference for Cu (the training odour) was significant $P < 0.02$ (two-tailed test). Likewise, the 16 young exposed to Cin showed a subsequent preference for that odour during the choice tests—mean preference score = +4.50 ($P < 0.01$, two-tailed Wilcoxon test).

Having ascertained that infant *Acomys* young prefer a chemical stimulus to which they had been exposed for 24 h (in their home cage) over a novel chemical stimulus, we next wished to determine whether conspecific young would show similar preferences as a function of a relatively brief exposure period during which the chemical stimulus would not be associated with any conventional reinforcer. This was investigated by exposing *Acomys* young 2–12-h-old to the odour of either Cin or Cu for a single period of 1 h, and individually testing them in a series of two-choice preference tests (as above) 24 h after the exposure period.

During the exposure session, all of the young from a given litter were removed from the home cage and parents and placed together into an acrylic cylinder (exposure chamber). A second cylinder (odourant chamber) containing a teaspoonful of the appropriate training substance (either Cin or Cu) was linked to the exposure cylinder by neoprene tubing (18 inches long) with a filter placed over the end entering the odourant chamber. Air was forced from the odourant chamber, through the filter and tubing, and into the exposure chamber; thereby exposing the young to the airborne odour of either Cin or Cu. The young were returned to the home cage immediately following the exposure period, where they remained until testing 24 h later. A total of 29 young mice (from 12 litters) were used in this experiment, with 15 being exposed to Cin and 14 to Cu.

A statistical analysis of the preference scores for all 29

young indicated that the exposure odour was preferred significantly over the novel odour during the choice tests ($P < 0.01$, two-tailed Wilcoxon test). Further analyses indicated that the mean preference score of the 15 young exposed to Cin was $+2.13$ ($P < 0.025$, one-tailed test) and -1.86 for the 14 young exposed to Cu ($P < 0.025$, one-tailed test). Thus, the exposure odour was preferred over the novel odour—regardless of whether the young mice had been exposed to Cu or Cin.

The survival value of such rapidly acquired stimulus preferences in this precocial murid rodent would seem to be similar to that of imprinting in avian species. In each instance, early attachment to a specific stimulus complex would serve to decrease the likelihood of the neonate wandering away from the parental figure or home area, and thereby decrease the possible risks of predation, starvation, or exposure to the elements. While precocial avian species tend to rely primarily upon visual cues for early stimulus attachments⁹ precocial species of macrosomatic mammals (such as *Acomys*) might be expected to rely primarily upon olfactory cues to mediate early attachments^{1,6,10,11}. There is, however, some evidence to suggest that other sensory modalities may function to some extent in attachment formation of both precocial avian and macrosomatic mammalian species. Gottlieb¹², and Porter and Stettner¹³, for example, report that hatchlings of several species of precocial birds become attached to specific auditory signals as well as visual cues; while Sluckin¹⁴ has found that visual imprinting may occur in guinea pigs. Thus, even during the first few days of life, stimulus attachments and preferences in these species are possible in other than the most salient sensory modality.

Evidence for a dual central role for angiotensin in water and sodium intake

ANGIOTENSIN II induces short-latency water intake when infused intravascularly or injected into certain brain regions of mammals^{1,2}. But conceptual difficulties arise if one asks why this should be so, and whether the data reflect real physiological actions. For example, angiotensin is a pressor hormone formed from kidney-based renin in response

to challenge such as hypotension and hypovolaemia^{3–7}. Water ingestion, in itself, is not an adaptive response to such challenges, since most ingested water is distributed intracellularly and will not relieve a vascular crisis. An adaptive response to hypotension or hypovolaemia would involve ingestion of an isotonic mix of fluids, since this would most rapidly and effectively increase vascular volume. In fact, hypovolaemia does result in an immediate increase in preference for isotonic saline over water and a delayed (6–10 h) acceptance of unpalatable hypertonic salt solutions^{8,9}. But, a possible involvement of angiotensin as a rapid and direct facilitator of sodium intake (apart from a slow and indirect role through stimulation of aldosterone release) has not yet been reported and some evidence suggests that angiotensin may not play any significant role in regulating sodium intake in the rat^{10–12}.

We now present data indicating that angiotensin can rapidly facilitate Na^+ intake, resulting in selection and ingestion of a mix of water and electrolytes best suited to overcome deficits in circulatory volume or pressure.

Adult male rats of the Long-Evans strain, weighing 225 to 300 g, were anaesthetised with Nembutal and stereotactically implanted with 23 gauge cannulae in lateral preoptic nucleus, nucleus accumbens, or lateral cerebral ventricles. One week was allowed for recovery from surgery; during this time animals were individually housed with free access to food pellets and deionised water as well as the saline solution with which they would later be tested. Testing was conducted in the home cages with the positions of the water and saline drinking bottles kept constant. Angiotensin and carbachol (another central dipsogen¹³) were prepared with isotonic saline vehicle to a concentration of $500 \text{ ng } \mu\text{l}^{-1}$ and $1 \text{ } \mu\text{g } \mu\text{l}^{-1}$ respectively. Intracranial injections were of $1 \text{ } \mu\text{l}$ volume and ventricular infusions of angiotensin were carried out at a rate of $500 \text{ ng } \mu\text{l}^{-1}$ per 8 min over an 8 h period.

The effects of several thirst-inducing stimuli on intake of water and 1.8% saline (two-bottle choice tests) were observed in rats in normal water and sodium balance during a 1 h test period. In 32 rats, intracranial injection of angiotensin resulted in an average intake of 9.6 ml of water and 6.8 ml of 1.8% saline. Following carbachol, 15 animals ingested an average of 9.5 ml of water and only 0.5 ml of 1.8% saline. In 14 other rats, thirst was induced by subcutaneous injection of 5 ml of 1.5 M NaCl. Average fluid intakes after this intracellular dehydration were 21.7 ml of water and 0.9 ml of 1.8% saline. Thus, thirst induced by intracellular dehydration or by central cholinergic stimulation resulted in substantial intake of water only, with minimal intake of the normally non-preferred 1.8% saline, whereas central injections of angiotensin resulted in substantial intakes of both water and 1.8% saline.

If a potentiation of sodium as well as water intake is characteristic of angiotensin action, this should remain evident when animals that are deprived of water or sodium are stimulated with angiotensin. Intake of water and 1.8% saline was observed in 13 rats (1 h tests) when deprived of fluid for 24 h and when deprived of fluid for 24 h plus receiving central injections of angiotensin. Following deprivation alone, the rats consumed an average of 17.1 ml of water and 3.0 ml of 1.8% saline; following deprivation plus angiotensin, the rats consumed an average of 23.9 ml of water and 11.7 ml of 1.8% saline. Increased intake of water and saline noted with angiotensin was significant ($P < 0.01$, paired sample t test). A similar study was carried out on 10 animals, but with a 48 h period of fluid deprivation and a choice test between water and 2.7% saline. After 48 h of fluid deprivation, the average intake of water was 22.4 ml, and the average intake of 2.7% saline was 2.2 ml. After deprivation plus angiotensin, intake of water increased to 25.7 ml, while intake of 2.7% saline

suggest that angiotensin is one of the factors directly influencing the intake of sodium as well as water.

Exchange of neurotransmitter amino acid at nerve endings can simulate high affinity uptake

AXELROD¹ found that released noradrenaline is recaptured by presynaptic nerve terminals, and proposed reuptake as a mechanism for rapid neurotransmitter inactivation. Subsequent studies led to the identification of high and low-affinity components in the uptake of several putative neurotransmitters by nerve terminals²⁻⁷. Although the apparent K_m values reported for the high-affinity uptake of some neurotransmitters (notably amino acids) are comparable to those reported for the low-affinity uptake of other neurotransmitters, it is generally thought that the inactivation of most neurotransmitter amino acids is obtained through high-affinity uptake systems having a K_m of the order of 10^{-5} M. Indeed, the existence of a high-affinity uptake for a given substance is often considered to favour its being a neurotransmitter.

High-affinity uptake systems for neurotransmitter amino acids have been demonstrated by methods in which high tissue: medium ratios of radioactivity, simulating net uptake, might have been obtained by homoexchange^{8,9}. So far this possibility has been investigated, by ourselves, amongst others¹⁰⁻¹², by methods that could not give a satisfactory answer.

We have now explored the possibility that GABA, at concentrations used for studies on high-affinity uptake, can release GABA from the endogenous pool.

It seems that exchange can largely account for what has previously been interpreted as uptake. Purified synaptosomes¹³ were incubated in the presence of a very low concentration of ³H-GABA to label the endogenous pool, without altering its size significantly. Aliquots were then superfused with regular medium, which was replaced after few minutes by identical medium containing varying concentrations of GABA. The superfusion apparatus, which largely

Fig. 1 Stimulation of ³H-GABA release from synaptosomes by different concentrations of unlabelled GABA. Purified synaptosomes¹³ from adult rat cerebrum were resuspended in 0.32 M glucose, at a protein concentration of 5 mg ml⁻¹. Aliquots were diluted 1 : 10 in Krebs-Ringer medium²⁶; after 15 min equilibration at 37° C in a rotary waterbath, a small volume (1/100 of the final volume) of a solution containing 50 μM 2, 3-³H-GABA (New England Nuclear Corporation, specific activity 10 Ci mmol⁻¹) was added to the incubation flasks. After an additional 10 min, 1 ml aliquots of the suspension were placed on Millipore filters (0.65 μm pore) lying at the bottom of six parallel superfusion chambers¹⁴, the filters were washed, 3 ml of prewarmed, oxygenated, glucose-containing medium were added to each chamber, and the superfusion was started, at a rate of 0.47 ml min⁻¹ (ref. 14). After 5.5 min, 20 ml of medium containing varying concentrations of GABA were added to the chambers (arrow) and superfusion was stopped at 15 min. Fractions were collected every minute; the radioactivity of the effluent and that remaining on the filters was measured by liquid scintillation. All the solutions contained 0.1 mM amino-oxycetic acid to prevent GABA metabolism. In these conditions, over 90% of the radioactivity was recovered as unchanged ³H-GABA. These and subsequent experiments run without amino-oxycetic acid gave qualitatively similar results, but a significant amount of ³H-GABA metabolites was recovered. The radioactivity recovered in the first three fractions was at times more erratic, and is not presented. The radioactivity found in each fraction is given as a percentage of the total radioactivity recovered (filter plus total fractions). Each curve is the average of three experiments. ▲, 1 mM GABA; △, 100 μM GABA; □, 50 μM GABA; △, 10 μM GABA; ○, 1 μM GABA; ●, control.

Fig. 2 Effect of sodium deprivation on the release of ^3H -GABA from synaptosomes. Experimental conditions as described in the legend for Fig. 1, except that the medium used for superfusion contained 0.256 M sucrose instead of 0.128 M NaCl. The figure shows the radioactivity recovered in all the 15 fractions collected. The addition of 0.5 mM GABA to the Na^+ -free superfusion fluid had no appreciable effect on the release of ^3H -GABA. Other concentrations of GABA that were tried (10, 100 and 1,000 μM) were also ineffective. Each curve is the average of two experiments. \circ , Na^+ -free, 0.5 mM GABA; \bullet , Na^+ -free; \triangle , control.

prevents reuptake, is described elsewhere¹⁴. Superfusion with unlabelled GABA caused an immediate, dose-dependent increase in the efflux of ^3H -GABA (Fig. 1). The release was about doubled by 1 μM GABA and was increased several fold by a concentration of 10 μM ; both concentrations are in the range of the high-affinity uptake system^{4,6}. The radioactivity released reached a peak after a few minutes and then

decreased, because of dilution of the synaptosomal ^3H -GABA by unlabelled GABA entering the tissue. The stimulation of ^3H -GABA release showed a substrate specificity similar to that described for uptake. Among the various compounds tested, only γ -amino- β -hydroxybutyric acid was a strong stimulator of ^3H -GABA release (Raiteri *et al.*, unpublished). Homoexchange and heteroexchange of amino acids at millimolar concentrations has already been shown in brain slices^{15,16}.

On the basis of an endogenous GABA level of 19 ± 4 nmol per mg synaptosomal protein (G. L., and M. R., unpublished) and assuming that the ^3H -GABA is homogeneously mixed with the endogenous pool, the rates of ^3H -GABA release can be calculated from the percentage of radioactivity released at the peak of the curves (taking the immediate prestimulation level of radioactivity as 100%). These rates are comparable with the initial rates of GABA high-affinity uptake obtained in a previous study⁶. In particular, the release rate at a saturating GABA concentration (1 mM) was similar to the apparent V_{max} of the high-affinity uptake system. In some experiments, in which ^3H -GABA release was stimulated by adding 1 or 10 μM ^{14}C -GABA to the superfusion fluid, to measure the uptake of ^{14}C and the release of ^3H simultaneously, the calculated ^3H -GABA efflux was similar to the influx of ^{14}C -GABA. Even considering the approximation introduced by the calculation, these data suggest that homoexchange accounts for at least a large part of the radioactive GABA entering synaptosomes by the so called high-affinity uptake system. In the concentration range of the low-affinity system, however, the influx of ^3H -GABA (ref. 6) was greater than its calculated efflux, indicating that a net uptake of the amino acid took place.

It is known that GABA uptake is sodium-dependent¹⁷⁻¹⁹. We previously showed that the high-affinity uptake of GABA detectable in embryonic chick brain slices is more sodium-dependent than the low affinity uptake¹⁹. Sodium deprivation also seems to inhibit the high-affinity more than the low-affinity synaptosomal uptake of glutamate, aspartate, glycine⁷ and GABA (G. L., and M. R., unpublished). Figure 2 shows a rapid depletion of synaptosomal GABA content upon superfusion with sodium-free medium. Over 50% of ^3H -GABA present was released in 2-3 min and the addition of GABA (10-1,000 μM) to the superfusion fluid did not appreciably alter the release pattern. Extensive release and absence of any detectable homoexchange could well account for what looks like an almost complete inhibition of the high-affinity uptake of GABA.

If glycine behaved like GABA, then the exchange of glycine at low concentrations should be detectable in synaptosomes from the spinal cord, medulla and pons (where a high-affinity uptake system for glycine was described^{5,7} and where this amino acid acts as a neurotransmitter^{20,21}), but not in synaptosomes from the cerebral cortex (where only a low-affinity uptake system for glycine was detected^{5,7}). Figure 3 shows that synaptosomes from spinal cord and brain stem do indeed exhibit a dose-dependent increase in the release of ^3H -glycine upon superfusion with 10, 25 and 100 μM glycine. In contrast, cortical synaptosomes did not respond to the addition of glycine at concentrations of 10 and 25 μM , which are both in

Table 1 Changes in the levels of GABA and of radioactivity in media after incubation

Original concentration (μM)	0	1	5	10
% change in radioactivity		-49 (2)	-46 (2)	-36 \pm 5 (6)
Concentration expected (μM)		0.5	2.7	6.4
Concentration found (μM)	1.3 \pm 0.3 (6)	2.1 \pm 0.3 (5)	5.5 \pm 0.3 (6)	9.6 \pm 0.9 (12)

Synaptosomes from rat cerebrum, resuspended in 0.32 M glucose at a protein concentration of 4 mg ml⁻¹ were diluted 1 : 10 in Krebs-Ringer medium and equilibrated at 37°C for 15 min in a rotary waterbath. Then, a small volume (1/100 of the final volume) of a solution of ^3H -GABA was added, to give the final concentration reported in the first line. After 10 min incubation, the suspension was either filtered through 0.45 μm Millipore filters or centrifuged for 10 min at 10,000g. The radioactivity was measured in the filters (or pellets) and in the filtered medium (or supernatant). The concentration of GABA present in the medium after incubation was measured by an assay to be described elsewhere. Some data obtained by this assay were checked by a double isotope dansyl derivative method²², which gave essentially identical results.

Means \pm s.d. are presented. The number of experiments is given in parentheses.

the range of the high affinity uptake system^{5,7}, and responded only weakly to a concentration of 100 μ M.

In a set of typical uptake experiments run at low amino acid concentrations, we measured concentration and radioactivity of ³H-GABA in incubation media before and after incubation. In the presence of exchange, the decrease of concentration observed after incubation should be less than that of radioactivity. Table 1 shows that a large part of the radioactivity originally present in media containing 1, 5 or 10 μ M ³H-GABA was taken up by synaptosomes. Changes in concentration of GABA showed a different pattern. With 1 or 5 μ M GABA there was an actual gain in concentration, and with 10 μ M GABA a barely detectable, not significant decrease in concentration was observed. If one takes into account the 1.3 nmol ml⁻¹ of GABA appearing in the medium in the absence of added GABA, the net removal of GABA which seems to take place is much lower than that expected from radioactivity measurements.

In conclusion, homoexchange seems to be a major mechanism by which radioactive GABA is transported into synaptosomes when low substrate concentrations are used. A net uptake, which may or may not be of high affinity component, could be computed only after subtracting the large contribution of homoexchange; therefore the problem of the existence and function of the high-affinity net uptake of GABA and, possibly, of other neurotransmitter amino acids in synaptosomes should be re-evaluated.

Fig. 3 Effect of different concentrations of unlabelled glycine on the release of ³H-glycine from synaptosomes. Experimental conditions as described in the legend for Fig. 1, except that 0.5 μ M 2-³H-glycine (New England Nuclear Corporation, specific activity 11.1 Ci mmol⁻¹) was used to label the synaptosomal glycine pool. *a*, Synaptosomes from spinal cord, medulla and pons; *b*, synaptosomes from cerebral cortex. \square , 100 μ M Gly; \triangle , 25 μ M Gly; \circ , 10 μ M Gly; \bullet , control.

Interestingly, several properties (such as saturability and sodium-dependence) thought to be typical of GABA high-affinity uptake seem also characteristic of exchange. The utility of sodium-free media to characterise high-affinity uptake is questionable, because of the large loss of endogenous amino acid determined by this condition.

In view of our findings, it is possible that the specific labelling of certain populations of nerve endings by a given amino acid, observed in various experimental conditions^{7,24}, may occur through an exchange process. The data obtained with glycine seem to support this interpretation.

It should be noted, finally, that if reuptake by presynaptic terminals were the main mechanism of inactivation of the liberated neurotransmitter, an uptake system with a K_m of the order of 10⁻³ M (low affinity) might be as effective as one with a K_m of about 10⁻⁵ M. The possible contribution of post-synaptic areas and of glial cells^{22,23} to the reuptake process should also be considered.

We thank A. Coletti for assistance and U. Poce for the dansyl derivative determinations. This work was partly sup-

ported by a grant from the Italian National Research Council to M. R.

Stimulation of synaptosomal dopamine synthesis by veratridine

ISOLATED synaptosomal preparations maintain many of the functional properties of intact neurones¹ and the uptake of putative biogenic amine neurotransmitters such as noradrenaline, dopamine and serotonin, is well documented²⁻⁵. In addition, stimulation of synaptosomal catecholamine release has been demonstrated in response to depolarising concentrations of potassium^{4,6} or veratridine⁶, an alkaloid able to produce depolarisation in intact neurones by increasing sodium permeability^{7,8}. In intact adrenergic neurones stimulation of transmitter release is often accompanied by a concurrent increase in the rate of transmitter synthesis, possibly through a reduction in feedback inhibition of tyrosine hydroxylase⁹⁻¹³. The demonstration of a link between stimulated neurotransmitter release and stimulated synthesis in synaptosomes would be an important indication of the validity of studies of synaptosomal processes in order to gain insight into the functioning of intact neurones. We report here that striatal synaptosomes maintain the ability to respond to depolarising concentrations of veratridine with a calcium-dependent tetrodotoxin-sensitive increase in dopamine synthesis.

Male Sprague-Dawley rats (200–250 g) were decapitated and the striatum was dissected out and placed in polyethylene tubes in ice. The P_2 fraction (containing synaptosomes, mitochondria and myelin) was prepared essentially as described by Gray and Whitaker¹⁴. Most of the tyrosine hydroxylase activity in the P_2 fraction has been shown to be associated with the synaptosomal of this fraction after sucrose density gradient centrifugation¹⁵. The P_2 fraction was resuspended in a Tris-buffered incubation medium, with 15%–20% of the P_2 from one rat used for each incubation. Dopamine synthesis was measured by incubating the tissue with L-1-¹⁴C-tyrosine and monitoring the production of ¹⁴CO₂, as previously described¹⁶. Essentially all newly formed dihydroxyphenylalanine is converted to dopamine under these conditions¹⁶. Synthesis was proportional to tissue and time for at least 30 min. The uptake and efflux of L-3,5-³H-tyrosine was measured by separating the tissue from the medium on a Millipore filter, as previously described¹⁶.

To measure the effect of stimulated catecholamine release on the rate of dopamine formation, synthesis was measured during exposure to veratridine. Blaustein *et al.*⁶ have demonstrated that synaptosomal catecholamine release is increased by exposure to veratridine. As Table 1 shows, veratridine produced a 50% increase in synthesis of dopamine. In intact neurones veratridine-induced depolarisation is prevented by treatment with tetrodotoxin, which seems to block sodium entry¹⁷. Blaustein *et al.*⁶ have shown that tetrodotoxin blocks the veratridine-induced increase in synaptosomal amine release. Similarly, Table 1 shows that the veratridine-induced increase in synthesis is prevented by earlier treatment with tetrodotoxin. Tetrodotoxin alone has no effect on dopamine synthesis.

The uptake of labelled tyrosine was inhibited by veratridine—the percentage control uptake 2 and 5 min after exposure to veratridine was 67%±2% and 60%±2% respectively ($N=6$). Veratridine also stimulated the efflux of labelled tyrosine after *in vitro* labelling. The amount of labelled tyrosine remaining in the tissue 2.5 and 5 min after exposure to veratridine was 70%±3% and 65%±4% of controls, respectively ($N=6$). That both the decrease in uptake and increase in efflux of tyrosine seem to be equally affected by veratridine suggests that the specific activity of tyrosine in the tissue is not increased by veratridine; but since this preparation consists of synaptosomes from several different transmitter systems (as well as free mitochondria), measurements of labelled tyrosine uptake and efflux in the total preparation may not reflect alterations that might occur in tyrosine-specific activity in the dopaminergic synaptosomes.

It has been shown repeatedly that for transmitter release to occur from nerve endings, the presence of extracellular calcium is necessary¹⁸. This is also true for veratridine-induced synap-

Table 2 Calcium-dependence of the veratridine-induced increase in dopamine synthesis

	–Ca ²⁺ _o	Dopamine synthesis (nmol L ⁻¹ g ⁻¹) –Ca ²⁺ + EGTA	–Ca ₃₃
Controls	13.8±0.22 (18)	13.8±0.41 (18)	12.8±0.72 (10)
Veratridine	18.1±0.30 (18)*	14.4±0.44 (18)	12.0±0.82 (10)

Aliquots of the striatal P_2 fraction were incubated for 5 min at 37°C either in control medium, Ca²⁺-free medium containing 1 mM EGTA, or simply Ca²⁺-free medium, followed by the simultaneous addition of veratridine (7.5×10^{-5} M) plus L-1-¹⁴C-tyrosine (1×10^{-5} M) or by the addition of tyrosine alone, and incubated for an additional 5 min. Values represent the mean ± s.e.m. The number of observations is in parentheses.

* $P < 0.001$ controls.

somal amine release⁶. Table 2 shows that the increase in dopamine synthesis that usually occurs in response to veratridine was prevented when calcium is omitted, with or without the chelating agent ethyleneglycol-bis- $[\beta$ -aminoethylether]NN'-tetracetic acid (EGTA). It is important to note that in order to demonstrate a consistent increase in synthesis, it was necessary to measure synthesis during the initial 5-min exposure to veratridine. For example, if the tissue was preincubated for 10 min with veratridine and then labelled tyrosine was added and synthesis measured during the next 10 min, a significant increase was not observed. A similar time-dependency has been observed with the increase in synthesis produced by increased potassium¹⁶. Whether or not this time-dependency of the increase in synthesis is related to a similar time-dependency of transmitter release has yet to be determined.

These results demonstrate that isolated synaptosomes can respond to depolarising concentrations of veratridine with a calcium-dependent increase in the rate of catecholamine synthesis. These findings show that the interact neurone is not necessary for the production of a stimulation-induced increase in neuro-transmitter synthesis, and are consistent with the suggestion that synaptosomes are capable of a depolarisation-induced transmitter release⁶. These observations may be relevant to studies of neurotransmitter synthesis not only in adrenergic, but also in serotonergic and cholinergic synaptosomes.

Table 1 Effect of tetrodotoxin on the veratridine-induced increase in dopamine synthesis

	Dopamine synthesis (nmol h ⁻² g ⁻¹)
Controls	9.54±0.53 (12)
Tetrodotoxin	9.50±0.57 (12)
Veratridine	14.7±0.46 (12)*
Tetrodotoxin + veratridine	10.5±0.43 (12)

Aliquots of the striatal P_2 fraction were incubated for 5 min at 37°C either without further additions or in the presence of tetrodotoxin (2×10^{-7} M), followed either by the simultaneous addition of veratridine (7.5×10^{-5} M) plus L-1-¹⁴C-tyrosine (1×10^{-5} M) or by the addition of tyrosine alone, and incubated for an additional 5 min. The apparent rate of synthesis was calculated by dividing the d.p.m. of product formed per hour per gram of original tissue by the specific activity of the tyrosine added to the medium. The normal incubation medium had the following composition: NaCl, 125 mM; KCl, 5 mM; CaCl₂, 1 mM; MgCl₂, 1 mM; glucose, 10 mM; ascorbic acid, 1 mM (made fresh daily); and Tris-HCl, 50 mM pH 7.4. Values represent the mean ± s.e.m. The number of observations is in parentheses.

Suppression of fibrinolysin T activity fails to restore density-dependent growth inhibition to SV3T3 cells

SMALL quantities of proteolytic enzymes added to cultures can cause untransformed fibroblastic cells to manifest transiently the altered growth potential^{1,2}, enhanced lectin-mediated agglutinability³ and enhanced glucose transport⁴ characteristic of fibroblast cultures transformed by oncogenic viruses. Thus, the enhanced proteolytic activity of cells transformed by both oncogenic DNA viruses^{5,6} and RNA viruses⁷ may play an important role in the loss of density-dependent growth inhibition exhibited by virus-transformed cells. In particular, Reich *et al.* have shown that cells transformed by simian virus 40 (SV40) or Rous or murine sarcoma virus produce increased levels of a proteolytic activity (fibrinolysin T) which hydrolyses ¹²⁵I-fibrin^{8,9}. This fibrinolysin T activity is the result of the conversion of serum plasminogen to plasmin by a plasminogen activator (cell factor)^{10,11}. In addition, using plasminogen-deficient serum prepared by affinity chromatography, Reich *et al.* have demonstrated plasminogen dependence of several phenotypic parameters associated with viral transformation¹². We have used ε-aminocaproic acid (EACA), an inhibitor of plasminogen activation¹³ and fibrinolysin T activity⁸, and found that suppression of the fibrinolysin T activity of SV40-transformed 3T3 (SV3T3) cell cultures does not restore density-dependent growth inhibition to these cells. This suggests that the enhanced plasmin level in SV3T3 cell cultures is not responsible for loss of density-dependent growth inhibition in this cell line.

We added medium containing 10 mg ml⁻¹ (76.3 mM) EACA (Sigma) to Swiss SV3T3 cells after plating them on ¹²⁵I-fibrin coated dishes⁸, and simultaneously determined the effects of EACA on cell growth and release of ¹²⁵I-fibrinopeptides. The results (Fig. 1 and Table 1) show that fibrinolysin T activity was relatively low on the first and second days after plating the SV3T3 cells, but by the end of the third day in culture extensive hydrolysis of the ¹²⁵I-fibrin was apparent. (Because the cell sheet peeled off the Petri dish at cell densities greater than 12 × 10⁶ per dish, fibrinolysin T could not be assayed on untreated SV3T3 cells after day 4.) In contrast, fibrinolysin T activity in EACA-treated cultures remained low and relatively constant for at least 7 d after plating. The inhibitory effect of EACA on fibrinolysin T activity was rever-

Fig. 1 Growth and fibrinolytic activity of Swiss SV3T3 cells treated with ε-aminocaproic acid. At time zero, 5×10^6 Swiss SV3T3 cells in 5 ml of Dulbecco's medium + 10% foetal calf serum were seeded into 60-mm Falcon plastic Petri dishes coated with ¹²⁵I-human fibrinogen ($10 \mu\text{g cm}^{-2}$; total radioactivity 1.17×10^6 c.p.m. per dish) which was converted to fibrin before plating cells according to Unkeless *et al.*⁸. Five hours later, the medium was removed and 5 ml of fresh Dulbecco's medium + 10% foetal calf serum with or without 10 mg ml^{-1} EACA was added (↓). At 24-h intervals thereafter, the cell culture medium was removed, aliquots were assayed for released ¹²⁵I-fibrinopeptides as described⁸, and replaced with 5 ml fresh medium with or without EACA. The amount of released ¹²⁵I-fibrinopeptides on appropriate control plates without cells and with or without EACA has been subtracted. The activity detected represents the accumulated radioactivity during a 24-h incubation period. Each point represents the mean value (\pm s.d.) of the average of duplicate counts of replicate determinations on separate plates. Cell growth was determined on ¹²⁵I-fibrin-containing plates which were seeded in parallel with those used for enzyme assays. In each case the medium was changed at 24-h intervals. Cell counts were determined on trypsinised cell suspensions using a laser beam cell counter (Cytograph). Fibrinolysin activity: ○, control; ●, EACA-treated. Cell number: □, control; ■, EACA-treated. After removal of EACA, both fibrinolysin activity (●, ○) and cell number (■, □) increased during the next 24 h.

sible, since changing to medium without EACA on day 6 resulted in extensive release of ¹²⁵I-fibrinopeptides during the next 24 h (Fig. 1). Most important, under conditions where fibrinolysin T activity had been suppressed 83-98% by EACA, Swiss SV3T3 cells continued to grow and eventually reached the same cell density as the untreated control culture. Thus, essentially complete suppression of the fibrinolysin T activity of SV3T3 cell cultures failed to restore density-dependent growth inhibition to these cells.

As Fig. 2 shows, the fibrinolytic activity of untreated Swiss 3T3 cells was also relatively low for the first 2 d after plating, increased sharply on days 3 and 4, and then decreased on days 5 and 6. We have evidence from other experiments (unpublished data) that elaboration of cell factor depends on the growth state of the culture and is decreased when 3T3 cells become confluent. This may account for the diminution of fibrinolytic activity on days 5 and 6 (Fig. 2), although depletion of the ¹²⁵I-fibrin substrate may also be responsible in part. EACA (10 mg ml^{-1}) treatment of 3T3 cultures leads to 92-100% inhibition of their fibrinolysin T activity (Table 1). In addition, EACA treatment caused 3T3 cells to cease increasing in cell number about 2 d earlier than untreated cells and at a lower final cell density (EACA-treated: 8.7×10^5 cells per dish; untreated: 1.5×10^6

† Activity of cells 24 h after removal of EACA from growth medium.

Fig. 2 Growth and fibrinolytic activity of Swiss 3T3 cells treated with ϵ -aminocaproic acid. Experimental details and symbols are as described for Fig. 1. Swiss 3T3 cells were seeded at 5×10^5 cells per dish.

cells per dish). The inhibitory effects of EACA on the final cell density and fibrinolytic activity of 3T3 cells were also partially reversed within 24 h after removal of EACA (Fig. 2).

Treatment of 3T3 and SV3T3 cells with 10 mg ml^{-1} EACA for 45–48 h inhibited incorporation (c.p.m. mg^{-1} protein) of a mixture of radioactive amino acids into acid-precipitable material by 40% and 45% respectively. Similarly, incorporation of ^3H -uridine into acid-precipitable material was inhibited 21% (SV3T3) and 15% (3T3), and incorporation of ^3H -thymidine was depressed 10% (SV3T3) and 40% (3T3). Since we have previously shown that treatment of these SV3T3 cells with low doses of cycloheximide depresses protein synthesis and leads to a dose-dependent growth inhibition¹⁴, the decreased growth rate of EACA-treated SV3T3 cells was probably a consequence of the inhibition of protein synthesis in EACA-treated cultures. Inhibition of protein synthesis by EACA may also have been responsible for reducing the final cell density of EACA-treated 3T3 cells (Fig. 2)¹⁴.

Studies on the metabolism of ^{14}C -EACA (New England Nuclear Corp.) have demonstrated (1) that EACA is taken up into a trichloroacetic acid (TCA)-extractable pool by both Swiss 3T3 and SV3T3 cells to approximately the same extent on a per cell basis and (2) that EACA is quite stable in cultures of both cell types since less than 0.2% of the input ^{14}C -EACA was broken down and reincorporated into TCA-insoluble cellular material during a 24 h incubation (R.O.R., B.Ash and P.H.B., unpublished data). The high anti-fibrinolytic activity and metabolic stability of EACA, coupled with its low cytotoxicity, thus make it a useful agent with which to probe the involvement of fibrinolysis in viral transformation.

Our results demonstrate that extensive fibrinolysis takes place under normal growth conditions in cultures of both untransformed 3T3 and transformed SV3T3 cells. This is so, even though the cells were cultured in medium containing foetal calf serum, which contains relatively high levels of inhibitors of fibrinolytic activity^{8,9}. Our assay for fibrinolytic activity differs from others, however, in that it measures cumulative proteolytic hits over a prolonged period. Prolonged incubation may be required to detect low levels of fibrinolytic activity since the ^{125}I -fibrin substrate is a complex, multi-stranded, cross-linked molecule and more than one proteolytic cleavage may be required to liberate ^{125}I -fibrinopeptides into the medium.

It is also interesting that the untransformed 3T3 cell line exhibited greater fibrinolytic activity per 10^6 cells during the growing phase than did its SV3T3 counterpart (Table 1). Thus, SV40 transformation of 3T3 cells did not appear to lead to increased levels of intrinsic fibrinolytic activity in SV3T3 cells.

Removal of EACA from SV3T3 cultures, however, resulted in considerably more fibrinolytic activity per 10^6 cells than was observed when EACA was removed from 3T3 cell cultures. Thus, there appeared to be a relative reduction of fibrinolytic activity in dense cultures of 3T3, but not SV3T3 cells. The nature of this density-dependent reduction of fibrinolytic activity is under investigation.

At the concentration used in these experiments (0.076 M), EACA probably interferes with fibrinolytic activity in several ways. It can inhibit activation of plasminogen to plasmin by cell factor^{8,13}, probably by binding to and altering the conformation of plasminogen¹⁵. EACA may also interact with fibrin and thus directly inhibit the hydrolysis of fibrin by plasmin¹⁶. Finally, EACA may reduce the amount of available cell factor through its inhibition of protein synthesis. Ambrus *et al.*¹⁷, however, have reported circumstances under which EACA almost completely inhibited the fibrinolytic activity of plasmin while it failed to reduce the caseinolytic activity of similar plasmin preparations. Thus, in our experiments, although the fibrinolytic activity of the EACA-treated cultures was almost eliminated, residual plasmin activity for other substrates may have remained. We are investigating whether such residual plasmin activity exists and whether it plays a role in loss of density-dependent growth inhibition.

Our results show that essentially complete suppression of fibrinolysis T activity failed to restore density-dependent growth inhibition to SV3T3 cells. In addition, we observed high levels of fibrinolytic activity in growing cultures of both 3T3 and SV3T3 cells and only when confluent 3T3 cells were compared with growing SV3T3 cells did the SV3T3 cell cultures exhibit higher fibrinolytic activity per 10^6 cells than the 3T3 cell cultures. Thus, the enhanced fibrinolysis T activity of SV3T3 cells is unlikely to be the cause, but may rather be a consequence of unrestrained cell growth. Our results are consistent with those of Ossowski *et al.*¹², who showed that while complete expression of several phenotypic properties of transformed cells (such as growth in agar, and morphology) required the presence of a serum plasminogen fraction, SV40-transformed hamster cells grew to high cell densities in plasminogen-depleted serum.

Human fibrinogen was provided by the American Red Cross National Foundation Center with the partial support of a grant from the National Institutes of Health. This research was supported by a grant from the National Institutes of Health. I.N.C. holds a postdoctoral fellowship from the National Cancer Institute and R.O.R. is a faculty research associate of the American Cancer Society.

Activation of guanyl cyclase and intracellular cyclic GMP by fibroblast growth factor

THE induction of cell growth by animal serum in quiescent cultured fibroblasts is preceded by a sequence of regulated steps¹. These steps include stimulation of cellular transport systems¹, protein synthesis¹, ribosomal and tRNA synthesis² and eventually the induction of DNA synthesis followed by cell division^{3,4}. Two of the earliest changes observed after growth induction by serum are a transient increase in intracellular cyclic GMP⁵ (10-fold) and a decrease in cyclic AMP (two-to-threefold)^{5,6,7}. It has been suggested that cyclic GMP acts as a positive intracellular signal for cell growth since intracellular cyclic GMP concentrations showed an early transient increase upon growth induction by phytohaemagglutinin whereas no changes were observed in cyclic AMP concentrations⁸, and additions of high, non-physiological (10^{-6} to 10^{-4} M) concentrations of cyclic GMP can induce substantial increases in DNA synthesis in resting fibroblasts⁵. Recently a new polypeptide hormone, fibroblast growth factor (FGF), was isolated from bovine pituitary glands⁹. FGF in combination with the glucocorticoid, hydrocortisone, and a nonspecific carrier protein, bovine serum albumin (BSA), can completely replace exogenously added serum in bringing about all the steps leading to the initiation of DNA synthesis and cell division in some lines of BALB/c 3T3 cells¹⁰. Hydrocortisone, as it fails to initiate DNA synthesis alone in the absence of serum¹¹ is considered to potentiate the action of FGF⁹ (permissive effect).

Here we show that physiological concentrations of FGF with hydrocortisone cause the same transient increase in intracellular cyclic GMP concentrations of quiescent cultures as those caused by serum. Little or no alteration, however, is observed in cyclic AMP concentrations. Furthermore FGF specifically activates the membrane-bound guanyl cyclase, but not the adenylyl cyclase system. We suggest that growth-initiating polypeptide hormones interact with a guanyl cyclase system bound to the plasma membrane, in a way similar to that of the well known interaction between polypeptide hormones and the adenylyl cyclase system¹².

When FGF was added to resting BALB/c 3T3 cells maintained in the presence of serum² the concentrations of cyclic GMP rose after 10 to 20 min by a factor of 10- to 15-fold over the value in unstimulated cultures. Thereafter the concentration rapidly declined reaching approximately twice the value in resting cultures within 1 h (Fig. 1a). Cyclic AMP concentrations showed a reduction of only 20%, much less than the two-to-threefold decrease observed after addition of serum⁵. The concentrations of cyclic GMP approached those of cyclic AMP for a short time—a result similar to that obtained by adding serum to these cultures⁵ and by adding phytohaemagglutinin to human peripheral blood lymphocytes⁸. It was not possible to maintain non-degenerating cultures of BALB/c 3T3 cells with only BSA in the absence of serum, but addition of low concentrations (0.1 ng ml^{-1}) of FGF could prevent deterioration of the cultures for at least 7 d (ref. 5). Addition of

Fig. 1 Kinetics of cyclic nucleotide changes. BALB/c 3T3a cells¹¹ were grown as previously described⁵. For *a*, (FGF) cultures were allowed to become quiescent at a final cell density of 1.2×10^6 per plate before addition of 50 ng ml^{-1} FGF. For *b*, (insulin) BALB/c 3T3b cells², 6-d cell monolayers, washed with DEM, were incubated for 16 h in Dalbec's modified Eagle's Medium containing $250 \mu\text{g ml}^{-1}$ BSA and $0.5 \mu\text{g ml}^{-1}$ hydrocortisone (final cell density as *a* before addition of $5 \mu\text{g ml}^{-1}$ insulin (bovine pancreas, Calbiochem B grade). At the times indicated 10 plates were isolated as previously described⁵ and the cyclic GMP (—●—, —▲—) and cyclic AMP (—○—, —△—) were determined by a radioimmuno assay¹⁸. After centrifugation and ether extraction half the samples were digested with 3' - 5' cyclic nucleotide phosphodiesterase and all the samples were purified over Dowex Columns⁹ prior to assay. Results for digested samples (0.1 and 0.5 pmol for cyclic AMP and cyclic GMP respectively) were deducted to yield the final results expressed in $\text{pmol per } 10^6$ cells. Duplicate experiments agreed to within 15%. Parallel cultures radioactively labelled with ^3H -thymidine (Fig. 2) from 10 to 28 h after addition of FGF, insulin, or nothing incorporated 22, 10, or 0.6×10^3 c.p.m. into DNA, and 89%, 44% or 1.5% of the cell nuclei became labelled with radioactivity.

FGF was purified from bovine pituitary glands as previously described⁹. The possibility that FGF was acting on the cells to potentiate the action of trace amounts of other growth factors adsorbed to BSA was excluded by obtaining the same results as in Fig. 2 after replacing BSA by gelatin and completely synthetic polypeptides. It was also unlikely that minor growth-promoting impurities in the insulin preparations²⁴ were responsible since similar results were obtained from commercial preparations of insulin which were further purified by column chromatography.

increasing concentrations of FGF in the presence of hydrocortisone caused concomitant increases in both the cyclic GMP concentrations measured at 20 min and the eventual induction of DNA synthesis (Fig. 2) and cell division (not shown). Virtually no changes were observed in cyclic AMP, and the small changes observed in Fig. 1 may be due to other components in serum. Resting cultures were maintained with hydrocortisone long enough for the glucocorticoid to exert

its permissive effect¹³. Omission of hydrocortisone caused a four-fold drop in both DNA synthesis and cyclic GMP concentration and hydrocortisone alone did not induce early changes in cyclic nucleotide concentrations (Fig. 2).

High, non-physiological concentrations of insulin (10^{-7} M to 10^{-6} M) can also increase DNA synthesis and cell multiplication¹⁴ after addition to quiescent fibroblasts. At these high concentrations (100 to $1,000 \times$ physiological) both the early transient increase in intracellular cyclic GMP and the depression in cyclic AMP were observed in cultures resting in the presence of serum (not shown), or in medium free of exogenously added serum with hydrocortisone (Fig. 1b). Maximal increases in DNA synthesis and in cyclic GMP concentrations were only approximately 35% to 40% of those observed for FGF in Fig. 2. The concentration dependence for the increases in cyclic GMP concentrations and for the stimulation of DNA synthesis were roughly parallel (maximal from 10^{-7} M to 10^{-6} M; not shown), perhaps suggesting a correlation. Conversely, the initial depressions in cyclic AMP occurred at much lower insulin concentrations, in the normal physiological range (10^{-10} M to 10^{-9} M; not shown). Without hydrocortisone the changes in cyclic nucleotides and the eventual stimulation of DNA synthesis were reduced two- to threefold.

Fig. 2 Variations of cyclic GMP with FGF concentrations. Cell cultures were grown as in Fig. 1 except that 6 d after plating (confluent cultures) cell monolayers, washed with DEM containing 0.12 ng ml^{-1} FGF and $250 \text{ } \mu\text{g ml}^{-1}$ BSA, were then incubated for 2 d in this medium. Then $0.5 \text{ } \mu\text{g ml}^{-1}$ cortisol (hydrocortisone, Calbiochem) was either added (circles, triangles) or omitted (squares, lozenges). After 10 h (final cell density 1.1×10^6 per plate) varying amounts of FGF were added. *a*, Ten Petri dish cultures for each concentration were isolated 20 min later for cyclic nucleotide determinations (Fig. 1). Results are expressed in pmoles of cyclic AMP (open circles, squares) or cyclic GMP (black circles, squares) per 10^6 cells. *b*, Parallel cultures were also radioactively labelled with $3 \text{ } \mu\text{Ci ml}^{-1}$ ³H-methyl-thymidine at $3 \text{ } \mu\text{M}$ (for DNA synthesis) or $1 \text{ } \mu\text{M}$ (for autoradiography) from 8 to 26 h after additions. The c.p.m. of ³H-thymidine incorporated into DNA per culture (black triangles, lozenges) or the percentage of radioactively labelled cell nuclei (open triangles, lozenges) was recorded as before². Control additions of cortisol alone showed no changes in the intracellular cyclic nucleotide concentrations after 20 min or detectable increases in DNA synthesis.

Hitherto guanyl cyclase in a variety of tissues was thought to occur primarily in the membrane-free cytoplasm of the cell^{15,16}, unlike the adenylyl cyclase which is attached to the plasma membrane¹². Recently, however, a large increase in guanyl cyclase activity was obtained after treatment of particulate (membrane-containing) cell fractions with non-ionic detergents¹⁷. This finding was confirmed for 3T3 fibroblasts by the results in Table 1, where a ten-fold stimulation of guanyl cyclase activity in the particulate (microsomal) cell fraction was observed after Triton treatment, little or no increase being seen in the membrane-free cytoplasmic activity. The guanyl cyclase in the particulate fraction was also stimulated nearly three-fold by additions of FGF. No activation of the soluble cytoplasmic activity was observed, and the greatly enhanced activity in the particulate fraction after Triton treatment could not be increased by subsequent addition of FGF. Isolation of the plasma membrane fraction also confirmed these results: FGF stimulated the guanyl cyclase activity approximately sixfold whereas insulin had little or no effect (Fig. 3a).

The production of cyclic GMP during this reaction was measured by a radioimmune assay¹⁸. Even larger stimulations (eight- to tenfold) were achieved when radioactive cyclic GMP was isolated by chromatographic procedures from reaction mixtures containing ³²Pα-GTP, at higher GTP concentrations (0.001 M) (not shown). FGF, unlike insulin^{19,20} failed however to reduce the adenylyl cyclase activity of the plasma membrane (Fig. 3b). All incubation mixtures contained 3'-5' nucleotide phosphodiesterase inhibitors (theophylline and caffeine) to minimise phosphodiesterase cleavage of the newly synthesised cyclic nucleotides, as production of small quantities of one cyclic nucleotide could possibly affect rates of breakdown of the other²¹.

In a system uncoupled from other intracellular events FGF directly stimulates the guanyl but not the adenylyl cyclase of plasma membrane; presumably through a similar mechanism to that of the known hormonal stimulation of the adenylyl cyclase system¹². This is manifested in intact cells maintained in culture without added serum by a rapid, transient increase in intracellular cyclic GMP shortly after addition of FGF, little or no early changes being observed in cyclic AMP. Physiological

Table 1 Subcellular distribution of guanyl cyclase

Cell fraction	Cyclic GMP synthesised (pmol/min/mg extract)				
	Control	+ FGF	+ Triton	+ FGF	+ Triton
Supernatant	23	20	27	31	
Microsomal	9.4	27	97	108	

BALB/c 3T3a cells were grown in 10% serum as described (Fig. 1a). Cell monolayers were washed with Tris-buffered saline detached and centrifuged. This and subsequent operations were at 4°C . Cells, resuspended at 10% to 15% v/v in Buffer A (0.005 M Tris-HCl ($\text{pH } 7.4$), 0.0002 M MgSO_4 , 0.25 M sucrose) plus 0.00025 M dithiothreitol (DDT) were homogenised by douncing. The homogenate was made 0.001 M in EDTA Na_2 and centrifuged at $2,000g$ for 5 min. Then the supernatant was made 0.005 M in MgCl_2 and centrifuged at $150,000g$ for 2 h. The microsomal pellet was resuspended in Buffer A + 0.00025 M DTT and stored with the microsomal-free supernatant at 4°C . Reaction mixtures (0.5 ml) contained 0.04 M HEPES ($\text{pH } 7.6$) (N-hydroxyethylpiperazine-N'-2-ethane sulphonic acid), 0.009 M MgCl_2 , 0.0001 M GTP, 0.0005 M EDTA Na_2 , 0.0005 M DTT, 0.12 M sucrose, 0.01 M theophylline, 0.02 M caffeine $200 \text{ } \mu\text{g}$ of supernatant protein or $110 \text{ } \mu\text{g}$ of microsomal protein and where indicated 100 ng of FGF and 1% Triton X100. Reactions were incubated at 37°C for 15 min, terminated by boiling for 3 min, followed by centrifugation at $1,000g$ for 10 min, and the extracts stored frozen. Duplicate $20 \text{ } \mu\text{l}$ samples were assayed for cyclic nucleotides by the radioimmune assay (Fig. 1), and results are expressed as pmol cyclic GMP synthesised per min per mg protein. Blank values at zero time (5.3 and 2.7 pmol for supernatant and microsomal fractions) were deducted. The blank cyclic GMP values may be in part due to non-enzymic synthesis of cyclic GMP from GTP during the boiling step which nevertheless would be less than 2 pmol per reaction mixture, whereas non-enzymic synthesis at 37°C would be negligible²². In control reactions the cyclic GMP synthesised was fully digested with 3'-5' cyclic nucleotide phosphodiesterase, synthetic reactions were linear with time up to 30 min, and there was no interference of FGF or Triton at concentrations used in the radioimmune assay.

It has been possible in recent years to look at the British Association for the Advancement of Science from a slightly lofty viewpoint and wonder whether it is worth preserving. The annual meeting, the only occasion on which the association has surfaced, has also become a fairly regular occasion for pointed editorialising about an organisation that had outgrown its usefulness. No longer is this a reasonable line to take, and for that great credit above all to Magnus Pyke whose unique qualities have done much to breathe life into the body. If we talk here about the way ahead it is not without feeling admiration for the achievements of the recent past.

What, if anything, do scientists, those interested in science, and indeed those confronted with science need from a national organisation with a wide potential membership? Clearly not another forum for technical discussion; there are enough of these as it is, and why would a scientist take his latest results to Stirling when he could ride them to Stockholm, San Francisco or Sydney. Nor is it obvious that mere presentation and explanation of science to an enthusiastic audience will be other than an activity of moderate interest to scientists, particularly as the quality of science presentation by other media is often high.

There remains, however, a field which is as yet almost unexplored—the study of science itself. In this supplement we have tried to draw attention to some facets of science to which any scientist could contribute and from which he could draw some intellectual satisfaction. The history, sociol-

ogy, philosophy and way of going about science; the borderlands where science meets other disciplines; the morality of science; the way that science is presented to the public—there is much fertile ground here for regular discussion. To which we could add the deployment of scientists, science in defence, science in the Third World, education for scientists, government policy for science, nationalism in science. These are all subjects that scientists should have special knowledge of without needing to integrate a differential equation or operate a microscope. They emphasise common experiences, and may be the way towards bridging the gulf, both personal and professional, between teachers, academics, and scientists in government and industry. Here is also scope for the amateurs of science to make significant contributions to the world of learning.

The British Association is the ideal vehicle for all this, with its potentially very broadly based membership and its lack of political colour. It can point already to the increase in throughout-the-year activities both of its younger members and of its *ad hoc* committees. What is needed now is more nation-wide activity amongst its general membership and a vigorous campaign to persuade scientists that the study of science itself makes them a better practitioner. Cells of mutual instruction and discussion, rather like the Mechanics Institutes of the nineteenth century, could do the scientific community, in its broadest sense, much good and are well worth the serious attention of the association in the coming years. □

Stirling University, host to the British Association

Tom Willoughby

Flat 3, 16 North Side, Clapham Common, London SW4, UK

In this article an architect examines how the university campus at Stirling was planned. He also describes a computer study of the site carried out at the University of Strathclyde as part of a project on computer-aided design of large building complexes.

THOSE lucky enough to go to the British Association conference at Stirling this September will find one of the most beautiful campuses in Britain, sited near the citadel of Stirling Castle, the anvil on which much of Scottish history was hammered out. For Stirling is a town over which England and Scots battled for centuries, and where, in the absence of the English, the Scots fought amongst themselves. The almost unscaleable crag on which Stirling Castle stands is the gateway and key to the Highlands. Stirling had the lowest dry crossing of the Forth at the 'auld Brig' and with the resulting trade and patronage of the Scots royal house, the town grew to a prosperous centre.

The Romans under Agricola occupied the rock as a natural defence in 82 AD, legend has it that King Arthur fought the Saxons over the castle, and from 1194, in the reign of King Alexander I, the town became the 'favourite resort for the royal house'. The victorious Edward I of England pushed into Stirling in 1296, routing the locals, but Wallace replied by defeating the invaders. The English were down but not out and Edward returned; after a furious siege, they retook the castle. By 1313 the indomitable Scotsman Bruce had the castle under siege, and the following year Edward II marched to its relief but was blocked fair and square at Bannockburn where Bruce won a much hailed victory. Bruce then dismantled the castle to prevent its misuses by the dreadful English but Edward III was soon back and so the battles continued. The Scottish kings from Richard III to James VI resided with the court at Stirling. The uncertain form of the Scottish state, with its bloody tribal or clan wars, litters the royal history with assassinations, torture, plots and counter plots but, by the time of James VI, the framework of laws and Parliament were established, although the Western Isles chiefs were never cowed in the same way as the English Barony. The battle of Sheriffmuir in 1715 saw the highlanders and lowlanders fighting it out. In 1745 the castle was strongly held for the protestant crown, but catholic Prince Charles took the town in triumph. The town Stirling reflects the royal patronage with the castle and the magnificent store of buildings such as the 'Argyll Ludging' one of the finest examples of Scottish renaissance extant, built in 1630 by the Earl of Stirling.

New university

Returning to the present day, the 1950s and early 1960s saw the change of government policy towards an expansion of higher education, culminating in the long awaited Robbins report which recommended six new universities of which at least one, if not two, should be located in Scotland. The new university was to be the first for 300 years on Scottish soil, which, interestingly, boasts four ancient universities whereas England has only two.

The burgh of Stirling decided in October 1960 to do all in its power to attract the new university. Its competitors

were six other Scottish towns—Ayr, Cumbernauld, Dumfries, Falkirk, Inverness and Perth—which simultaneously entered the fray to attract the project.

The University Grants Committee (UGC) felt that it wished to found universities in medium sized towns, where people welcomed a new university, where land was cheaply available and the existing town offered prospects for the development of town-grown facilities. An investment in terms of capital, expanded job opportunities and cultural pump priming, provided by a university, would act as a regenerative force, possibly attracting specialised light industry into the bargain.

The lobbying was enthusiastic if not downright aggressive, Inverness arguing the benefits to the Highland economy, Stirling and Falkirk their nearness to the main centres of industry and population. Cumbernauld was felt to be too new, Perth to be near the university towns of Dundee and St Andrews, Dumfries and Ayr to be too isolated. The argument was really between Inverness, Falkirk and Stirling, with leanings towards the latter two.

The Falkirk-Grangemouth area is one of the most rapidly expanding in Europe, even more so with the advent of North Sea Oil. Falkirk could accommodate a university with both technical and humanities faculties and the town was large enough to offer a choice of 'digs' or rented flats. But middle class nonindustrial Stirling offered a magnificent site.

When looking at university planning in the stringent financial climate of 1974, one should not forget those heady days of the 1960s when governments jealously viewed each other's 'graduate count' as an international virility symbol. The euphoric days saw the UGC dispensing rapidly expanding resources and the choice of Stirling related to the general pattern of UGC policy. In Britain, as in many other parts of the world, university planning is as dominated by the Oxbridge ethos as vicars are by Gothic. Universities are in stone towns, in 'nice places'; thus historic York, although surrounded by existing universities, gets a new

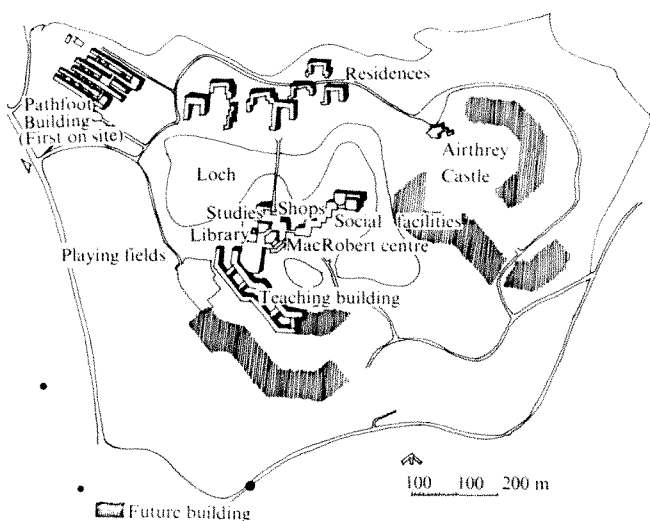

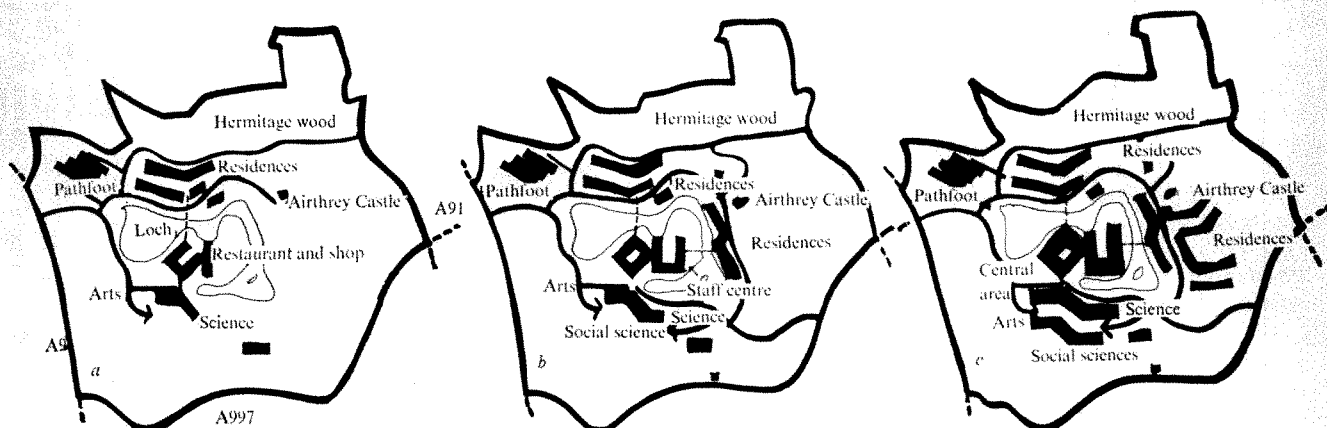

Fig. 1 Present site plan for a campus for 3,000 students.

university, whereas industrial Teesside just to the north, an industrial conurbation three times the size, does not. Almost incredibly, prosperous Bath, a mere 12 miles from the existing and famous University of Bristol, gets a new university; the town, although stone, pretty and small like Stirling, being almost incapable of supporting facilities that allow the word 'universities' to have much meaning. In their more lunatic moments, people were even suggesting Stamford, a town of 10,000 but oh! such a pretty place. The ivory tower concept dominated the pattern of thinking and in this way Stirling was selected while Scotland's fastest growing population centre was passed by.

Fig. 3 An area of the site around the lake.

The decision in favour of Stirling, when announced, was rightly made final, but of course there were howls of anguish from Inverness. In Falkirk where the committee chairman, Andrew Duncan, had made getting the university his life's work, bewildered and bitter comments about 'the snob town' of Stirling were heard.

Stirling is on the new A80 from Glasgow and the M9 for Falkirk and Edinburgh, and this and the sheer magnificence of the site were major factors in its selection. The site of over 300 acres on the Airthrey Estate lies between the west slopes of the Ochills and the wooded area of Abbey Craig on which stands the splendid Wallace memorial, a flamboyant victorian bombastitude from which the view is well worth the climb. The site had an existing maternity hospital in the old castle and of course this had to be closed, the town council thus neatly securing a new university and guaranteeing the building of a new £1 million maternity hospital.

The first vice-chancellor, Tom Cottrell, was appointed in 1965 and set out the main objectives: there were to be three main areas of study, arts or humanities, basic sciences and social sciences. From the start it was intended that there would be minimal boundaries between these, thus continuing the valuable traditional assets of a general education given within the Scottish schools system. In 1967, 1968 and 1969 the university was to take 130 to 200 students, in 1971 a further 603. In 1972 the intake was 640, the intention being to have a steady 3,000-5,000 students by 1975. Although there is room on the university site for further expansion, the present budget will not allow this for the time being.

Buildings

The design and building programme was the responsibility of the architects Robert Matthews, Johnson Marshall and Partners. In 1966, the development plan was published, and has, in its essentials, been followed.

The first building, 'Pathfoot', was rapidly erected and positioned so as not to inhibit future development; it served to get the academic programme off the ground. Temporary buildings were wisely avoided as they have to be upgraded or demolished later, or more likely are still in heavy use 30 years on. Pathfoot, a simple set of parallel blocks following the contours of the site and linked by crossing corridors down the slope, is one of the least obtrusive and most successful buildings; it has won several design awards (Fig. 1).

Fig. 4 Each cell has a value showing ease of building.

The architects took the artificial lake at the centre of the site as the natural focus. The main non-residential buildings to the south are the teaching, research, library and private study buildings. The object, as can be seen on development plans, is to extend southwards as student numbers grow. The level areas of the site are reserved for playing fields. The general proposed expansion can be seen in Fig. 2a, b and c. At the centre of the campus the MacRobert Centre has been built to provide an arts centre for both town and gown. The southernmost of the nonresidential buildings is the teaching block which is designed as a continuous form along the contours, expanding eastwards and southwards. A student may be involved in up to five departments within the broad based course structure and the housing of all teaching under the same roof makes mobility simple.

Although priority has always been given to the academic building programme, several coffee bars and club rooms have now been added or are under construction. The residences are built to the north of the lake and provide accommodation for two-thirds of the students. The UGC does not offer finance for residences and it is quite an achievement for the university to have raised the money by appeal and borrowing to build these blocks. The budget for the architect has obviously been very tight but the spartan interior has merit and is quite adequate. The rooms are arranged in flats or in halls of residence, the flats being generally the more popular though the halls give more seclusion for those wishing to work.

Computer study

The plan for Stirling University by Robert Matthews has made a great deal of the site. The consistency of the external cladding materials (some students say monotony) does not detract from the natural beauty of the setting. As a result of interest in university planning, a computer-aided study of the best development strategy for Stirling University was carried out at the University of Strathclyde. It was suggested that both the residential and teaching blocks should be south of the lake initially and the northern areas developed later. In addition, it was contended that with a compact development the site could accommodate a university of 12,000 students with all necessary facilities excepting some sports fields. The study attempted to develop a computer-aided design tool to assist in the laying out of large complexes of buildings. For illustrative purposes an area of the site was taken around the lake (Fig. 3).

To develop a layout plan or zoning for functions on this

The University of Stirling. With the lake as a centrepiece the site is an unusual one for a University.

site the strength of the relationships between different functions of the university was expressed on a scale from 1 to 10, a relationship of 10 being the essential need for immediate contact. Thus each department of the community, such as administration, arts, chemistry, was assigned a number describing how strongly it was connected with each of the others.

In addition, to allow for the difficulties of building on the site, a grid was drawn on the plan (Fig. 4) and in each square a number was assigned which reflected how 'buildable' that part of the site was. Plainly the lake has zeros whereas the areas to the south with gentle slopes and good foundation conditions are easily and cheaply built on and score highly.

In this way a numerical picture of what the site was like and how the university functions were interrelated could be presented to the computer. In principle, the function, faculty or department needing to have access to all others is placed on the site by choice of the designer and the others are located after this by a simple computer algorithm, to minimise the dislocation expressed in the need for proximity on the 1 to 10 scale. Rather than an actual building layout, the result is a series of zones on the plan indicating in which area a new building should be located from the point of view of easy communication and planning efficiency (Fig. 5). Various experimental computer routines were developed for three-dimensional zones and graphic outputs. The study, although simple, does provide another point of view and certainly the suggestion of a compact development, leaving larger areas of the site unspoilt, would have produced a completely different character on campus; whether it would have been better is a matter for argument.

Relationships

The University of Stirling, like any other new institution in a town, needs time to get to know its environment and to win over the town people. Its position on an isolated campus, without any substantial residence in the town, does not help. Certainly the MacRobert Theatre has been used by local dramatic societies and visiting theatre companies to the benefit of Stirling and the whole region but, as yet, there seems little use by the town of the university sports facilities; recently the university refused to go part way with the town on financing a joint swimming pool, preferring to build a small one of its own while the town built another.

It was hoped that the new employment brought by the university would encourage industry but this has not, as yet, occurred. Of course the university now employs over

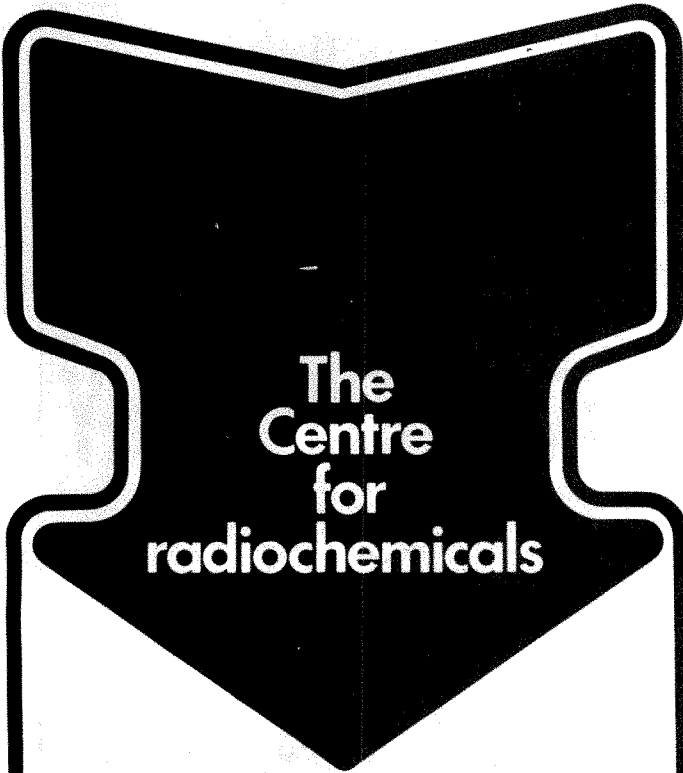

Fig. 5 The zones for a student population of 3,000.

1,000 people, which is in itself a boon; yet conversely, while more clerical and other jobs have been created so the number of people coming to Stirling expecting to find such work has increased and the availability of jobs for the local people does not seem to have markedly improved. Perhaps the most difficult point with a separate campus is the provision of all facilities on the spot—bookshops, banks and supermarkets. This is a great pity, for surely a university bookshop located in the town would provide an invaluable specialist service a small population cannot support. Perhaps if residences can be built in town in future these things may come about. A good example of how a university can generate new shops can be seen in the streets around the University of Glasgow.

The University of Stirling and the town should start thinking now about the effect of future growth of the campus; after all, a student population of 6,000 would give the campus a daytime population of about 1,000, which in a town of 28,000 will have a significant impact. The road programme and problems of general access may well have to be reassessed, as well as a monumental parking problem.

The university authorities, students and architects have done well to achieve a rapid build-up to the present almost complete campus. This has been done despite problems both logistic and academic. The courses offered are already diverse and include MSc and PhD courses in the pioneering aquatic pathology department, a unique educational degree that combines supervised experience with academic study allowing students to teach immediately on qualifying, and an Institute of Finance and Investment which offers one-year courses.

Stirling University, famous for its student outbursts in the past, now gives the impression of consciously trying to achieve a real community spirit while determined to develop a town-gown understanding. There is undoubtedly an underlying pride and mutual confidence developing between the town of Stirling and its university.

What makes a good science writer?

David Fishlock

Financial Times, Bracken House, Cannon St, London EC4P 4BY, UK.

David Fishlock is Science Editor of the Financial Times.

SOME years ago a friend of mine mentioned to another research scientist that he intended to become a science writer. His colleague commented drily that it meant he would need to know ten times as much as he ever wrote on any aspect of science. That advice sometimes comes to mind when I am writing against a daily newspaper deadline in the late afternoon or early evening, aware that I am stretching my own knowledge of the subject to the limit, with no time to seek further advice. More often, however, I recall it when I am reading reports of other science writers who, whether for lack of knowledge or because their own prejudices have insulated them from the other side of the story, reveal all too plainly that their writing has outdistanced their knowledge.

Accuracy and indignation

The professional scientist's constant complaint against science writers is that they get it wrong; that they imbue with all the authority of Science some observation, opinion or conclusion which at best is open to argument and at worst is factually incorrect or misleading. It is a grievance I hear in many laboratories I visit, as well as in Whitehall and corporate headquarters. It is one of which I was made very firmly aware soon after I joined the *Financial Times* in 1967. A scientist who has since risen to become one of the government corps of scientific advisors told me bluntly that he didn't waste time reading newspaper reporting of science.

More recently the indifference this physicist then showed has changed into a genuine concern at the top of the profession for the damage that misunderstandings, inaccurate reporting and biased comment can do when published by newspapers under the authoritative sounding by-line "Our Science Correspondent". Examples range from an interruption, on wholly spurious grounds, to efforts to clear up

the oil leaking from the Torrey Canyon, to fears unnecessarily aroused by hypothetical representations of the 'hazards' of pesticides, herbicides, drugs, toiletries, nuclear reactors and nuclear by-products, supersonic airliners, and many other products of applied science. Reports that readers might reasonably expect to be written from a standpoint of some knowledge and expertise are all-too-often characterised largely by indignation and prejudice.

Indignation has tended to be the keynote of far too much science writing in the past few years. When, in the second half of the 1960s, it dawned on the public that science and technology did not have pat solutions to man's social ills and if exploited too greedily might even exacerbate them, many science writers joined enthusiastically in the assault on scientists' motives. They competed for space in some journals to the point where it was hard to distinguish their writing from that of a new breed of specialists which emerged at that time, called Environment Correspondents, created by many newspapers to provide 'gloom and doom' stories forecasting the imminence of mankind's destruction. For editors it was a fresh angle on the insatiable public thirst for bad news.

Also deeply infected by indignation at this time was the weekly journal *New Scientist*. Soon after it started in 1956 its founder-editor Percy Cudlipp, who had been one of the most eminent of Fleet Street editors, wrote that his journal was to be a

"link between science and industry. It would report technological innovations and promising lines of research. It would pay careful attention to the scientifically progressive sections of industry and would help, by describing their activities, to create a growing interest in scientific applications among industry as a whole."

In the early years its highly authoritative explanations of every facet of technology and science, written wherever possible by the foremost practitioners in a particular field, yet painstakingly edited—when necessary—for assimilation by the inexpert, were eagerly seized upon by other writers as well as by scientists anxious to keep abreast of progress

in science, if only to see that their interests were not being neglected in the goldrush.

Lest I leave the impression that early *New Scientist* editors hung on to every word, each prediction of the wise men of science and engineering, let me hasten to say that by the start of the 1960s the journal was making its own critical appraisals of projects and plans. Increasingly it was finding flaws in the proposals for harnessing science. In short it was attempting—sometimes with conspicuous success, as in the case of an ill-conceived scheme for large cross-Channel hovercraft-ferries¹—what later became dignified as the new discipline of 'technology assessment'.

Influence

The *New Scientist* has had an important influence on science writing in Britain, and probably elsewhere too. Although I do not think it has bridged the gap between the 'two cultures'—by this I mean that few people who are not professionally concerned with science trouble to read the journal—it has bridged many narrower gaps between the scientists themselves. It has also been invaluable to science correspondents on other journals, as the first stage of breaking down a complex piece of research or 'emerging opportunity' into a simple but lucid newspaper story.

Unfortunately, the influence of *New Scientist* began to wane sharply in the late 1960s. The downturn coincided with a change of publisher, from a small but dedicated company to a large and remote empire. It also coincided with two changes of editor, both of whom interpreted their role not as helping scientists to adapt to the changing attitudes of society towards science and technology, but as lending their weight to the attack. What characterised many of its editorial assaults at this time was not the cool, dispassionate and knowledgeable writing which distinguished so many of its early articles and leaders in the first decade of the journal's life, but the irrational, emotion-laden tirade of the writer who is composing for effect and not going to allow himself to be deflected or confused by facts.

A low threshold of indignation is the *sine qua non* for the successful investigative reporter, of the kind that exposed the Watergate debacle in the *Washington Post*, for example. But as the two Pulitzer prize-winning reporters in this case make so plain in their book *All the President's men*² they also exercise uncommon care in sifting and double-checking their facts and deductions before publication. (The rigorousness of this process may owe much to the fact that Howard Simons, their managing editor, who launched the paper's investigations into Watergate, was for many years its highly respected science correspondent.)

Too many science correspondents in the last few years have assumed that a low threshold in indignation and an input of information from someone, somewhere in science, however obscure, was enough to add up to a story. Too many have been ready to select facts and sources regardless of their intrinsic merit and to overlook a much greater weight of contrary evidence. Too many, in short, have flouted the basic principles of the profession they are being paid to write about, in quest of a story to meet the supposed public taste for gloom and doom.

A science writer who accepted without question claims for perpetual motion would be laughed out of court. But no less improbable assertions are often implied about the explodability of nuclear reactors, the hazards from radioactivity or the damage left in the wake of supersonic transports. The referee system of exposing a man's observations and conclusions to the scrutiny of his peers, who then approve or reject them for publication in an accredited journal, is the science writer's best safeguard against the dubious claim. It may not be perfect but it is much healthier than the activities of those scientists who have tried—sometimes with devastating success—to bypass the

journals and appeal directly to a general public in no way equipped to assess the merits of their claims.

Wit and grace

Scientists, understandably, have been at a loss to know how to respond to assaults from science writers. As that formidable United States physicist, the late Dr Edward Condon, once said ruefully, when assailed by a Congressman for allegedly being a security risk, "If you say I've got a wart on my nose, I can deny it. But if you just say I'm one of the ugliest men in town, all I can do is argue that I'm really quite pretty"³. Aggrieved scientists and technologists, attacked for the 'ugliness' of their discoveries, projects and propositions, sometimes turn for help to a science writer who may lend a more sympathetic ear. It is unfortunate but the impact of a dispassionate appraisal can rarely counterbalance the damage done by the preceding highly dramatised story. One instance where the counter-attack was very successful, however, came after lurid newspaper accounts of the mercury found in fish landed in Britain, when the science correspondent of *The Observer* reported that fish from the Smithsonian Museum, caught in the 1920s, had been shown to contain at least as much mercury when assayed by the same method.

The one real source of redress a scientist has who feels the facts have been ignored or distorted—and I can assure readers that it can be a very effective form of redress—is a brief letter to the Editor. Few newspaper editors will ignore a letter from, say, a professor or research director who says bluntly "your science correspondent was wrong". Fewer still will decline to publish it prominently if the letter puts the facts straight with some leavening of wit or grace.

If I have a general literary complaint about science writing and the reporting of science, technology and medicine, it is that so much of it is so humourless, so lacking in wit and charm. Nowhere is this more evident than in the stories that reek of indignation. Yet science itself is not at all like that. Names that come easily to mind of scientists who can be very witty about the failings and faults of their own profession include Victor Rothschild (as in his 1971 Royal Society of Arts lecture on the need for reorganisation of government science in Britain), Kenneth Mellanby and Magnus Pyke. Most recently, in the pages of *Nature*, we have the splendid example of Erwin Chargaff with a delightfully ironic essay, criticising the validity of much present-day biology and the honesty of such euphemistic evasions as "the results that I reported last year are based on facts that are no longer available"⁴.

Far too often the facts science writers reported last year are 'no longer available', either. Sometimes, inevitably, this is unavoidable, and no fault of the writer, who is simply reporting results, conclusions or claims, formally or publicly stated, that are later overtaken or invalidated by more research or other events. Sometimes it is the result of injudicious selection of 'facts', as was the case in a protracted (but quite unsuccessful) assault on a well known domestic pesticide by a journalist who, when I challenged his motives, simply said "Well, what's wrong with flies?" Sometimes, unfortunately, it is the result of misunderstanding, misinterpretation, or simply miscalculation—as when a prominent story in *The Guardian* of alleged pollution of the English Channel turned out to be based on calculations assuming that the channel had but two dimensions⁵.

Lessons

Seven years of reporting and appraising science, technology and medicine for the *Financial Times* has taught me some harsh lessons about the scope and limitations of newspaper reporting of science, and the pitfalls of taking too freely the word of its practitioners. A background which

includes experience of industrial science and of reporting industrial practice has encouraged, I think, more sympathy for the formidable difficulties of translating the discoveries of science into practice, often dismissed impatiently by science writers as mere parsimony or 'engineering detail'.

But it has also taught that the scope is much greater than the limitations; that given editors with a genuine interest and curiosity about science—its discoveries and opportunities and the people who make them and who take the decisions—the scope is immense. The *Financial Times* enjoys such editors, and has done so certainly since the post-war years when the late Professor Sir Francis Simon, head of the Clarendon Laboratory, Oxford, was also its science correspondent. It is a paper of industry and commerce, specialising in facts and fair interpretation and not dependent for sales on polemics, propaganda or unabashed entertainment.

As Science Editor I am one of about a score of specialised feature writers, mainly writing regular articles of up to 2,000 words—much longer than most newspapers normally accept—sometimes at the Editor's instigation but most of the time as a result of my own quarrying among the papers or people of science. In the past twelve months, for example, it has published over 70 feature-length articles under the by-line of its Science Editor, and many more on such technologies as aerospace and computers by other staff feature writers.

What I cannot claim is that those articles represent a complete spread of science and technology. The reader will find little on astronomy, genetics or sex-change surgery, for example. But he will find a more complete (and I would venture more accurate) coverage of the science, technology and politics of nuclear energy than any other newspaper has carried. He will also find many articles discussing the organisation, management and funding of science, rare indeed outside the pages of specialised journals on research management.

No two national newspapers in Britain produce a similar science coverage. You can take your pick from a wide variety of interests and levels of treatment, of preferences and prejudices. At its best the reporting of science compares favourably with that of such countries as the United States, West Germany or Sweden.

It has recently been proposed quite seriously to me that science correspondents should exercise as much responsibility as the referees of scientific papers. In principle, I agree and would like to see the suggestion developed more fully; but in practice I cannot imagine how such standards could be enforced, when science correspondents must work constantly under constraints called deadlines that no referee would tolerate.

What I think scientists are entitled to ask of those who write regularly about them is that they will exercise the basic tenets of the scientific approach; that they will reject illogical argument, that they will reject stories where the facts do not fit, that they will not suppress facts that conflict with their arguments. Newspapers nowadays employ very bright people as journalists, many of them university graduates. Most of them are perfectly capable of handling in an interesting and accurate way most of the science stories that come to light. If the science correspondent has any claim at all to distinction as a specialist writer it is surely that he is versed in the scientific method—the way scientists approach a situation—and thus better equipped to spot the fallacies for his readers.

The transit of Venus in 1874

A. J. Meadows

Department of Astronomy and History of Science, University of Leicester, Leicester LE1 7RH, UK

Observations of the 1874 transit of Venus seem to have been based on a misguided belief that nineteenth century techniques were superior to those of the previous century. Here A. J. Meadows explains, with the benefit of hindsight, how the expectations of the nineteenth century astronomers were not fulfilled.

THE average distance from the Earth to the Sun is a fundamental astronomical constant: it forms the basis of the scale of distance used both outside and within the Solar System. Outside the Solar System, the Earth–Sun distance acts as the base line for the measurement of the distances of nearby stars, and so, ultimately, of the entire Universe. Within the Solar System, any single estimate of distance can be used to calibrate all remaining distances by using Kepler's third law. For example, if we know the Earth–Sun distance we can work out the Venus–Sun distance:

equally, however, we can derive the Earth–Sun distance from a knowledge of the Earth–Venus distance at any instant.

The classical method for the determination of distance in astronomy has always been by the use of parallax. This requires three things: a relatively nearby object, a distant background, and two observers at either end of as long a base line as possible. When the observers measure the position of the object relative to the background, it does not seem to be in exactly the same place for both. The difference—the parallactic shift—decreases with the distance of the object; so the parallax provides a direct measure of the object's distance. The current value of the solar parallax is 8.794", although in fact, it is known to much better accuracy. Thus, two observers situated at the ends of an equatorial radius of the Earth would see the Sun displaced against the background stars by that amount. Clearly, the direct detection from Earth of so small a displacement of the Sun is virtually impossible. The prob-

lem of determining the solar parallax has, therefore, been one of finding a closer and easier object to measure than the Sun.

Observing Venus to determine parallax

Of all the planets, Venus comes closest to the Earth: its minimum distance from the Earth at conjunction is, on average, only half that of Mars. Unfortunately, the value of parallax measurements for Venus is diminished by its juxtaposition to the Sun when at conjunction, which makes accurate visual observation extremely difficult. The way out of this impasse was suggested by Edmond Halley in 1716. Venus usually passes above, or below, the Sun as seen from the Earth; but on rare occasions, because of the mutual inclination of the orbits of both planets, they are so placed that observers on Earth actually see Venus transiting the solar disc. Under these circumstances, the brightness of the Sun becomes an advantage, rather than a disadvantage, for Venus appears as an obvious and easily measurable, black dot on the Sun's surface. Halley proposed that, during a transit, Venus should be observed from several widely spaced stations on Earth. Observers at points distant from each other would see the planet describe slightly different paths across the solar disc. Therefore, the duration of a transit would depend on the observer's position. Measurements of the times of the beginning and end of the transit could therefore be converted into a value for the parallax of Venus at conjunction and, thus, into a figure for the solar parallax.

At the time the main problem with Halley's proposals was the infrequent occurrence of transits of Venus. At present, the transits occur in pairs separated by a gap of 8 years, but with a delay of over a century between successive pairs. In Halley's time, the next pair were not due until 1761 and 1769: but, to eighteenth-century astronomers, the wait seemed worthwhile, for the method apparently provided much greater accuracy than any other then available. (From his observations of a transit of Mercury in 1677, Halley estimated that a transit of Venus should provide a value for the solar parallax which would be accurate to one part in six hundred—far better than other eighteenth century methods.)

Great preparations were made for the transit in 1761, with expeditions dispatched to distant parts of the world'. But the results were a major disappointment: the extreme values obtained for the solar parallax differed by as much as 20%. It was generally agreed that the main inaccuracy had been introduced by an unexpected 'black drop' effect

Fig. 1 One of the huts erected at Greenwich for testing prior to observations of the transit of Venus in 1874.

Fig. 2 Observers waiting for the transit to begin.

as Venus encroached on to the solar disk. (As the limbs of Venus and the Sun approached they seemed to flow together—an effect that made accurate timing of the beginning and end of the transit very difficult.) Forewarned, the observers at the following transit, in 1769, obtained rather better agreement; but their results were not properly reduced until the 1820s, when the work was undertaken by the German astronomer, Encke. The final figure he obtained for the solar parallax was $8.571''$, a value that was widely accepted for a quarter of a century. By the latter part of the 1850s, however, it became evident that this made the Earth too far away from the Sun. Solar gravitation acts differentially on the Earth-Moon system because the Moon is sometimes closer to the Sun than is the Earth, whereas at other times it is more distant. As a result, the motion of the Moon is dependent on a factor that involves the mean distance of the Sun. By the mid 1850s lunar theory had become sufficiently refined to show that Encke's result could not satisfy the observational data on lunar motion. It therefore became essential to re-determine the solar parallax.

A different approach

In 1857, G. B. Airy, the Astronomer Royal, proposed that arrangements should be made for detailed observations of the next transit of Venus, due on December 9, 1874, to obtain a better value for the solar parallax. Airy was confident that the technical advances since the eighteenth century would permit a much more accurate result to be obtained. His colleagues agreed with him, and he was put in charge of a major British campaign (to be linked ultimately with similar campaigns mounted by a number of other countries).

One of Airy's first decisions was to abandon the use of Halley's method of observation, and to substitute instead one proposed by the eighteenth century French astronomer, Delisle. Halley's method, which involved timing both the beginning and the end of the transit, required that the entire transit should be visible from each observing station. This meant that any change in weather during the course of the transit could vitiate the result. More importantly, it meant that large areas of the Earth's surface, from which only the ingress or the egress could be seen, were ruled out as places for observation. Delisle's method, on the other hand, only required the timing of one contact—either ingress, or egress. To compensate for this, it required—in contrast to Halley's method—a very precise determination of the longitude of the observing station. Which approach was preferable depended on the particular circumstances of the transit; Airy's analysis of the 1874 transit suggested that Delisle's method would be more suitable. He therefore began to search for a series of

Quantimet 720

COMPUTERS THAT SEE ... &

MICRODENSITOMETRY

Using a light pen the operator selects a single cell and microdensitometry provides a measure of the total nucleic acid content of the nucleus plus cytoplasm. The Quantimet 720 can provide individual measurements of the integrated optical density for every cell in the field of view in just one tenth of a second.

MEASURE WHAT THEY SEE

0000006 0000000

PATTERN RECOGNITION

The Quantimet 720 counts only the mature neutrophils in this leukaemic blood sample while automatically rejecting the immature forms. The selection is based on the measurement of the area/perimeter² ratio which gives a measure of the regularity of the nucleus of each cell.

Quantimet image analysing computers measure anything you can see. They:

- ★ Look at anything—photographs, microscope images, cine films macro objects
- ★ Give exact numbers, sizes, assays, densities, shapes and statistics on everything in view
- ★ Recognise selected objects in images and measure them only
- ★ Provide this information at speeds up to 1,000 fields of view a minute.

Finnpipette

The best micropipetting system in the World

- Accurate
- The least expensive
- Has variable volume
- 4 instruments cover the range from 5 μ l to 5000 μ l.

Each unit has a micrometer scale giving a minimum of 45 and (depending on unit size) up to 160 possible settings. Thus one Finn timer is equal to at least 45 fixed volume pipettes.

THE INTERNATIONAL SOCIETY OF DIFFERENTIATION

(President J. Brachet)

announces the

SECOND INTERNATIONAL CONFERENCE ON DIFFERENTIATION

to be held in

Copenhagen, September 2-6, 1975

The conference will include sessions on:

- Cell surface and differentiation.
- Aspects of cell division and differentiation.
- Carcinogenic disorders and differentiation.

Communications on other topics, especially controversial aspects of cell differentiation are invited.

Conference Committee Members:

M. Abercrombie, E. J. Ambrose, R. Auerbach, J. Brachet, A. Braun, D. A. L. Davies, B. Ephrussi, W. Franke, H. Foltzer, F. Jacob, N. K. Jerne, C. Kafani, G. Klein, R. Levi-Montalcini, A. Lwoff, R. G. McKinnell, C. L. Markert, B. Mintz, N. Müller-Bérat, C. Pavan, B. Pierce, C. Rosenfeld, S. Spiegelman, D. Tarin, G. Tocchini-Valentini, S. Toivonen, G. Tomkins, D. Viza, D. Yaffe, T. Yamada.

Further information from:

The Conference Secretariat:
Dr. Nicole Müller-Bérat,
Statens Seruminstitut,
Artager Boulevard 80
Copenhagen S,
Denmark.

or the I.S.D. Secretariat:
Dr. Dimitri Viza,

Faculté de Médecine
Pitié-Salpêtrière,
105 boulevard de l'Hôpital,
105 boulevard de l'Hôpital,
75634 Paris Cedex 13, France.

Deadline for registration: 31st March, 1975.

Deadline for submitting abstracts: 15th May, 1975.

widely spaced stations from which that type of observation of the transit could be made. As the zone of visibility for the 1874 transit was centred on the Pacific, suitable sites necessarily tended to be situated on islands. That forced Airy into extensive consultations with the Hydrographer for the Navy, Admiral Richards; for the charting of Pacific islands still left something to be desired at that time.

Airy outlined his proposals for observations of the transit at a meeting of the Royal Astronomical Society in 1868. In the following year, another prominent member of the Society, R. A. Proctor, attacked Airy's conclusions, claiming, in particular, that Halley's method might well be applied to the 1874 transit, and proposing that a somewhat different set of stations should be selected with that possibility in mind. Airy took no notice, but pushed ahead with his own plans, and during 1869 he obtained a sum of £10,500 from the Treasury to finance them. In 1873, however, Proctor (who had meanwhile become Secretary of the Royal Astronomical Society) once again took up the argument. This time it was pursued before the general public, especially through the columns of *The Times*. At first, Airy resisted any change in the arrangements, but eventually he agreed that additional stations should be sought. This, if anything, only served to enhance the dispute, for Proctor and his friends now entered on a debate with Admiral Richards to discuss which new stations might be occupied. Richards, in exasperation, finally observed²:

"Enthusiasts no doubt there are who, however accomplished they may be as astronomers, are wanting and cannot but be deficient on many subjects which it is as necessary to take into account as astronomy in a question of this kind; and hence we are told to send to the Antarctic Continent and to visit a variety of small rocky islets interspersed over the Southern Ocean at distances from each other varying from 1,000 to nearly 4,000 miles, many of which are actual myths, while on those which do exist it is certain that there is no anchorage for a ship, and that even landing would be generally impossible."

Proctor was not prepared to let Richards have the last word. In a subsequent supplementary issue of the

*Monthly Notices of the Royal Astronomical Society*³ he produced a chart of possible observing stations, together with the annotation:

"The chart requires no explanation beyond perhaps the remark that the islands in the less-known regions have been taken from ordinary atlases (after comparison of several), in preference to the Admiralty charts; because . . . one naturally feels doubtful about Admiralty statements which would appear to be variable according to official requirements. It did not seem well to insert any island, or group of islands, in the chart with some such note as 'Here, if convenient to those in authority, there is an island,' or 'this group of islands can be regarded as a reality or a myth as may be required,' and so on."

There, however, he had overstepped the mark; for, as Editor of the *Journal* at that time, he published without reference to other members of the Society. When Richards complained to the RAS Council, the result was virtually inevitable: by the end of 1873, Proctor had resigned as Secretary, and the controversy over the transit died down.

Airy had begun preparations for the transit on the assumption that the actual times of contacts would be determined visually in much the same manner as in the eighteenth century, although with better instrumentation. It was soon pressed on him, however, that the rapidly developing art of astronomical photography should also be used along with the visual method. Initially Airy was dubious, but was eventually persuaded, more especially because De la Rue, the leading British exponent of astronomical photography, agreed to take charge of preparing the photographic instrumentation. Airy therefore obtained a further £5,000 from the Treasury for this type of work, and British expeditions observing the transit carried out a mixture of visual and photographic measurements.

The raw data from the expeditions was collected together at the Royal Observatory, Greenwich, and Captain Tupman, an army officer, was put in general charge of the reductions. The work dragged on slowly until, finally, Parliamentary pressure began to build up for immediate publication: the expenditure on the 1874 transit made it, after all, one of the most expensive single scientific investigations supported by the state up to that time. When, partly as a result of the pressure, preliminary conclusions were published in 1877, the difficulty facing Tupman and Airy became apparent. The new measures of the solar parallax were no more accordant than the eighteenth century measures had been. Airy, himself, derived a final value for the solar parallax of 876"; but this represented an average from values for ingress and egress that differed by 0.11". Moreover, Stone, HM Astronomer at the Cape, obtained, from the same data a value of 8.88". The photographic results were even worse. From these, Tupman obtained a solar parallax of only 8.08"; and an independent re-examination of the material only improved this to 8.17". Part of the problem was that the type of photographic instrumentation used by most British parties was not particularly suitable for transit measurements. But even American measurements, which were better arranged, did not achieve the expected results⁴. Indeed, the deficiencies apparent in the British observations, both visual and photographic, were to varying degrees, found in the results obtained by all the participating countries.

Looking back, the observations of the 1874 transit seem to have stemmed from a misplaced belief in the superiority of nineteenth century methods and instrumentation over those of the eighteenth century. Certainly, the 1874 transit, together with the much less enthusiastically observed transit of 1882, finally delivered the quietus to this form of solar parallax measurement. Nobody will consider it worth observing the next transit of Venus, in 2004, for this purpose. Yet the idea that the solar parallax can best be

Fig. 3 Photoheliograph observation of Venus near the solar limb.

determined by observation of Venus at inferior conjunction remains valid. The present standard method involves radar observations of Venus near this point in its orbit.

All the photographs used in this article are from the Royal Observatory archives, and have been made available by Lt.-Cdr. H. D. Howse (National Maritime Museum).

'Popularisation' of science

Maurice Goldsmith

Science Policy Foundation, Benjamin Franklin House, 36 Craven Street, London WC2N 5NG, UK

With the increasing dependence of the civilised world on science, the need is not so much for 'popularisation' as for understanding and critical appreciation of scientific advances if alienation from science is to be avoided.

ASTRAY one evening recently in an unfrequented cupboard at home, I came across a copy of that pioneer publication *Penguin Science News*: to be exact, issue number four, dated July 1947. And as I turned the pages to renew with delight this old acquaintance, the editor once again spoke to me—but with words of such innocence that I was obliged to shut him up. From this surprise reunion I came away with an embarrassed feeling of sophisticated guilt, not so much in disturbing the innocent but in realising that his simple views were still held so widely. Although techniques of communication of scientific ideas to the public have developed greatly in these past three decades the philosophy of the communicators has not.

In an editorial the editor claimed that "every scientific subject, without exception, can be made clear to the layman." He added, "All the ideas of science are basically simple and understandable by the average brain," and went on, "Provided an author really understands his subject himself and has enough space to write his expanded discussion in simple words, there is nothing under the sun which he cannot clarify and teach."

In those pioneer days of science writing, I too, had such innocent views. We did not understand then, and I am not sure that many of us have grasped even today, that communication means not only to send out messages but also to receive messages from the world about us. We were concerned then only with the communicator. We assumed that if he wrote simply and well—"Goldsmith," one famous editor said to me, "you must learn to write more compellingly, otherwise your readers will ignore you—and so shall I"—we would be read and understood. O, blessed paradisaical innocence! The final awakening came for me about 1950. I was puzzled because since 1945 we had exuded millions upon millions of words, written and spoken, on the nature of the atom, and I found that most people remained unhappily ignorant on this subject.

We were most successful in scaring them, however, so that fear and prejudice are impeding progress in, for example, the development of nuclear power plants. It is not sufficient to write clearly and well. Literate writing helps but it carries in itself no guarantee that understanding or even reading will follow. Although, I agree it helps.

This is in great part due to the primitive view of the popularisation of science which inspires so much of our thinking. It is as constricting to us as was the veneration of the circle to Galileo. He was neutral about Kepler's thesis that the planets moved in elliptical orbits because he

could not accept as significant any speculation which neglected the axiom that the circle is the perfect curved form. We are in bondage to a concept that I believe has been an important factor in alienating people from science. We have tended to use the term "popularisation of science" loosely to describe what we hope for rather than what actually happens. This is more than an exercise in semantics, for what we are concerned with is the definition of the social phenomenon which has blinded us into believing that we were enlightening the masses when the opposite was more true.

I believe it would be generally accepted that the popularisation of science is designed to make science popular (by which I mean intelligible) among non-scientists. The argument is that science is difficult to understand and that it requires to be translated into terms simple enough for the non-scientist to understand. This view has been expressed almost from the beginning of science itself.

But a certain knowledge of science spread among the public long before that. There have always been scholars and non-scholars, therefore always the need to interpret. We are aware that there was a weakness for the encyclopedic in the literature of the Middle Ages. The general cosmological system of Dante's *Divine Comedy* was based on Aristotelian, Ptolemaic and Christian ideas. The most widely read of mediaeval romances, the *Roman de la Rose* of 1270, contained statements on topics such as philosophy, medicine, physics, astronomy and theology.

In this way, general ideas about nature of the universe, the planetary system and the nature of matter were put into circulation.

The word 'science' began to enter the English language during the Middle Ages (the beginning of the 17th century.) It came from France, and was synonymous with knowledge. But the early Latin translators of Aristotle gave the adjective "scientificus" a technical meaning, and this was transferred to science to mean accurate and systematised knowledge. The Aristotelian theory of knowledge was the guide: you had "scientific knowledge" when you arrived at it demonstratively, not by experiment.

But with the beginning of modern science—first with the Copernican revolution in the mid-16th century, and then with the great age of science inspired by Galileo and Newton in the 17th century—the expression "scientific knowledge" came into use to distinguish this form of knowledge from common knowledge: that is, science and knowledge were coming to be regarded in England as no longer synonymous. Science came to stand for a particular kind of knowledge, whether derived by straight deductive logic (as in Euclid), or whether using observation and experiment (as in Bacon and Harvey.) But the full realisation of this did not come until almost the mid-19th century, as expressed, for example, in Herschel's *Discourse on the Study*

of *Natural Philosophy* in 1830.

In the 17th century, with the emergence of modern science, the new systems of the world began to be part of the education of the well-read person, and the new ideas were made available to the aristocracy and the middle class.

It was at this period that what has been described as "the first systematic written attempts at scientific popularisation" appeared. The first of the great popular expositors was Bernier le Bovier de Fontenelle (1657–1757). He must have been a delightful person. Voltaire considered him the most universal genius he had met. He was a rare person in his combination of scientific knowledge and love of literature. He was a nephew of the great Corneille, and a contributor to the *Mercure Galant*, a paper edited by another uncle, Thomas Corneille. He was appointed secretary of the Académie des Sciences in 1699, and like Oldenburg, the secretary of the Royal Society in London, he had wide contacts bringing him information on the new developments in science throughout Europe.

Fontenelle wrote particularly for the public of the "salons". His *Entretiens sur la pluralité des mondes* (1686) is in the form of a dialogue and is addressed to the needs of an imaginary marquise, "jeune, aimable et ignorante". His intention, he declared, "is to deal with philosophy (he means principally astronomy and physics) in the least philosophical manner possible; I have tried to develop it to a point where it shall be neither too dry for the gentry nor too superficial for the scientists . . ."

For Fontenelle, popularisation was a class matter. The plebs had no place in his dissemination. His works and those of the writers who followed him, such as the *Spectacle de la Nature* (1732) by the Abbé Pluche, were primarily for the aristocracy, the wealthy bourgeoisie, and the ladies of the Court. The story is told of Fontenelle that one day at the Café Procope, the famous intellectual centre of Paris in the 17th century, he declared: "If my hand were cram full of knowledge, I wouldn't open it for the people". And on the sixth evening of his *Entretiens* he advises the marquise: "Let us content ourselves with being a select little band and not disclose our mysteries to the people".

In fact, the popularising of science to a general public could not come about until public forms of education had made literacy more general, until the media of dissemination were more widespread, and until there was a demand. People needed to realise that there was something to know which they were missing.

The *Entretiens* may have been written for a need already expressed: for example, Molière's *Femmes Savantes* was 15 years before the *Entretiens*, and his middle-class women spent evenings in their attics trying with a telescope to see the people on the moon. I do not regard Fontenelle as a populariser of science. He was a gifted propagandist for scientific ideas.

If Fontenelle was not a populariser, then who was? For an answer we need to go to the end of the 19th century when science was becoming established as a full time occupation for professionals.

During the early 19th century there were efforts—following the impetus of the industrial revolution—to make science available to such as mechanics, but the movement led by Henry Brougham, founder of the Society for the Dissemination of Useful Knowledge in 1826, to give working men a scientific education was doomed to failure; scientific knowledge could not be secured by superimposing instruction in the sciences upon a highly inadequate system of State education.

Similarly, the Royal Institution founded in 1799 to train mechanics, within a few years became a centre of scientific "entertainment" for a select few. Thomas Webster, who was Clerk of the Works in the early days of the Royal Institution, wrote to Count Rumford in 1799 with a proposal to found a school for mechanics in the house of the

Royal Institution. Rumford was delighted with the scheme and it was accepted by him—and by the Managers after some hesitations. But, by 1802, Webster had been granted sick leave and the project was abandoned. Why? I shall quote Webster's own words, but we must bear in mind that these were written in 1837, 35 years after the events, and Webster was by then an old and rather frustrated man. He wrote: "But this project for improving mechanics, well intended as it was, which promised to be so useful, and which had already gained for the Institution 'golden opinions' was doomed to be crushed by the timidity (for I shall forbear to speak more harshly) of a few. I was asked rudely (by an individual I shall not name) what I meant by instructing the lower classes in science. I was told likewise it was resolved upon, that the plan must be dropped as quietly as possible. It was thought to have a dangerous political tendency. I was told that if I persisted I would become a marked man."

The popular presentation of science was still designed for a few and not for the masses. The widely popular lectures of men like Huxley and Tyndall were of significance only to those who could read and write, and thus had little effect on the working masses.

Until recently the popularisation of science has been a class phenomenon designed for a privileged minority. Today we must rid ourselves of this concept of "popularisation". It smacks of the condescending, of Victorian do-goodism, of a patronising aloofness irrelevant to today's needs. We do not need to make science popular in a world in which science is of key importance. A single experience of space technology is more educative in this regard than millions of words. Besides, we cannot make science popular in the sense that Huxley and Tyndall wished to. The atom bomb has put an end to that. The catastrophic power of modern science confronts each one of us with profound moral issues. Further, the specialist fragmentation of science and its speed of change renders invalid the view that scientific ideas can be made clear through popular presentation. It was surely easier to popularise science a century ago when physics was largely a study of pulleys, levers and electric circuits; when chemistry consisted of reactions and formulae; and when biology was concerned with classifying different genera and species of plants and animals.

The trouble with most science writing—and in this I include all the mass media—is that we seek still to present science as a collection of facts. The mathematician, Professor Hyman Levy, commented: "The trouble about science and scientific explanation is that it tends to be incomprehensible to anyone except the expert". We must abjure the concept of popularisation in a democratic and rapidly changing society.

What we need then is more public understanding of science, and more public appreciation of the impact of science. This can only be achieved through a continuing education programme. The *raison d'être* of such a programme should be to help us to escape from the shackles of the scientific past; how to deal with new situations and how to find new facts; how to assess facts critically; and how to be one's own 'science critic' as well as football, or jazz, or music critic.

As we become more dependent on science, we become more vulnerable as the thing that has not been, and whose consequence cannot be foreseen, becomes the thing that is. Speedy and planned adaptation is already our need. It will become more, and not less, urgent. The social scientist has a key part to play here. I suggest there may be a law of social vulnerability, that is, a particular stage beyond which people begin to demand action at what seem to them to be "the harmful consequences of the application of science", for example, the social problems of air pollution, land conservation, use of pesticides, and urban development. If such a law can be found, then we shall be able to prevent

much misery, by securing corrective action before consequences become so gross that great quantities of antibodies—pressure groups of various kinds—are generated by the body social.

The populariser of science, as he functions today, cannot disseminate the subtle ideas of science. These really cannot be understood without hard, disciplined effort. It may be said that my reaction against former naive ideas about popularisation has gone too far. Of course, I am not against popularisation. I want a redefinition, a re-examination of the philosophy of popularisation. I believe popularisation of science must give way to wide public understanding and appreciation of science.

Who should be responsible for the necessary programme of activity? Clearly, it should be in considerable part a government responsibility. Just as the nation ploughs back a certain percentage of the gross national product to do scientific research, so it should invest a certain percentage of the research and development budget in public understanding of science, to help society to contend with some of the social problems that the applications of research and development cause.

What I have said are subjective impressions, generalisations for which I apologise. We need desperately in this country a research programme into the communication of scientific ideas to the public. Many millions of pounds are being spent annually for this purpose through press, radio, television, films, books, exhibitions, and museums. I have guesstimated that this sum is at least £20 million a year. Our ignorance about the impact of these media is complete. We know damn all. We have no objective criteria for assessing the social usefulness or effectiveness of these

media. We have only box-office and subjective generalisations. These are just not good enough.

I am happy that Glaxo is awarding, in collaboration with the Association of British Science Writers, four annual prizes of £500 each for popular science writing. I had hoped that from its inception there would be built into it a research programme. I say this because the American Westinghouse Awards for Science Writing, which have been running since before the Second World War, are useless in this respect. Their records are incomplete, and no one can say whether the Awards do more than put dollars into the pocket of some science writers each year—and provide publicity for Westinghouse. I would like to know how science writing and the communication of scientific ideas have benefitted. I apply the same criticism to the annual Kalinga prize for science writing administered by UNESCO—incidentally, an award I was proud to help into being when I worked at UNESCO.

The communication of scientific ideas needs a new approach. We have somehow to cope with a situation in which although politicians, and the citizens who elect them, continue to think in idea-proof compartments, the beliefs, values and institutions which nourish them are subject to rapid change. We need a new type of communicator, a modern Fontenelle, a poet and a visionary, a scientist and a visionary. He can help us to meet the flight from reason originating from the false belief—one that the popular communicators have failed to counter—of the threat of a blind, self-motivating, all-possessing, juggernaut of science and technology. I expect that then the alienation of people from science—the confusion in a “horror of lost self” as Robert Lowell sees it—will cease.

Practising science in Northern Ireland

D. R. Bates

Department of Applied Mathematics and Theoretical Physics, The Queen's University of Belfast

The practice of science in Northern Ireland is no harder than elsewhere but unwillingness to come to Northern Ireland because of exaggerated fears of the risks causes concern.

WHEN I was invited to write this article I accepted without much hesitation, but my experience has taught me that the provision of plain answers is not enough. Some of these may leave the erroneous and distasteful impression that scientists are indifferent to suffering. The reason seems to be that in spite of, or perhaps because of, the exceptional intensity of news coverage which Northern Ireland has received there is a general lack of any real sense of proportion about the violence and about how it affects work. To reduce the likelihood of being misunderstood in this way, I shall first present data enabling the scale of the violence in Northern Ireland to be viewed other than in isolation.

Comparing violence

Death is only one of the consequences of violence but it is both the most terrible and the most clearly defined. For comparison, the annual violent death rate will therefore be taken as a relevant and convenient (though admittedly oversimplified) index of the distress caused. Following standard practice with mortality statistics it will be expressed as the rate per hundred thousand inhabitants.

Table 1 gives data on death rates due to the troubles¹. In compiling it no attempt was made to distinguish guerilla deaths from civilian deaths proper but the former are officially estimated to number about one third of the latter. The locally recruited security forces (Ulster Defence Regiment, Royal Ulster Constabulary and Royal Ulster Constabulary Reserve) are grouped together as they are an integral part of the community. The method of presenting the rates obscures the danger to which members of these forces and members of the Army are exposed but nevertheless is appropriate as the total of the rates R_{NI} shown in the last row provides some indication of the impact of the violence on the people of Northern Ireland. Scrutiny of the table, with the knowledge that the total mortality rate in 1969 was 1,080.2 (ref. 2), should be reassuring to a rational man but I own it does not prevent me from fretting if a

Table 1 Death rates (per hundred thousand inhabitants) arising from disturbances in Northern Ireland¹

Year	1969	1970	1971	1972	1973	1974*
Civilian	0.8	1.5	7.5	20.9	11.0	11.0
Local security forces	0.1	0.1	1.0	2.7	1.4	1.8
Army	0.0	0.0	2.8	6.7	3.7	1.5
Total R_{NI}	0.9	1.6	11.3	30.3	16.1	14.3

The more recent figures were supplied by the RUC Press and Information Officer.

* Entries in this column are based on first 6 months of year.

member of my family is late in arriving home when bombers have been active.

An obvious comparison to make is with the civilian death rates from air raids on the UK during the Second World War. These rates, R_{AR} , are given in table 2. Their mean value 21.7 is less than twice the mean value 12.4 of R_{NI} which will be designated \bar{R}_{NI} , but this is quite misleading because the best known descriptions of the effects of the air-raids refer to the Greater London area where approximately half the deaths occurred and where the death rates were extremely high. A clearer appreciation of the position can be gained by excluding the Greater London area from consideration. The mean value of R_{AR} for the rest of the United Kingdom and \bar{R}_{NI} are about equal. Destruction by a common enemy is of course easier to bear than destruction coming from within and arousing communal animosities.

Table 2 Civilian death rates, R_{AR} , (per hundred thousand) arising from air-raids on UK^a

1940	1941	1942	1943	1944	1945
50.0	44.4	7.0	5.4	19.3	4.2

In the United States the murder (including non-negligent manslaughter) rate, R_M , is correlated with the population of the town or city⁴. This provides a useful gauge for the troubles here. Referring to Table 3 it may be seen that on average R_M equals \bar{R}_{NI} in cities with a population of around a quarter of a million and equals the peak value of R_{NI} in the more notorious cities. As a garnish to the statistics I may mention that during the past 20 years, two members of the staff of my department have met with violence while in American cities (one shot at in Dallas because he witnessed a crime, another mugged in Los Angeles); neither of them has been injured as a result of the troubles—nor indeed as far as I can ascertain, has any member of the staff of the university.

Table 3 Murder rates, R_M , (per hundred thousand) in towns and cities of the United States (1970)⁴

No. of towns or cities in group	Population limits	Average population of member of group	Murder rate R_M
23,94	< 10,000	5,000	2.6
11,77	10,000–25,000	16,000	3.3
504	25,000–50,000	35,000	4.2
252	50,000–100,000	70,000	5.2
98	100,000–250,000	140,000	10.0
56	> 250,000	750,000	17.5
Selected cities			
	Philadelphia		18.1
	Houston		23.5
	Chicago		24.1
	Baltimore		25.5
	Dallas		28.7
	Washington DC		29.2
	Detroit		32.7
	Cleveland		36.1

The existence of very high murder rates in the United States causes much adverse comment but the existence of very high fatal accident rates R_A in many advanced countries passes almost unnoticed. Although fatal accidents are a greater hazard to life, they tend to be accepted apathetically as inevitable. A large number are undoubtedly inevitable because of human frailty but the width of the R_A range should kindle deep concern. Table 4 shows that the difference between R_A in England and Wales, where it is least, and R_A in most advanced countries is actually greater than \bar{R}_{NI} (12.4). Fatal accidents are so numerous (almost 50 d⁻¹ in England and Wales and over 100 d⁻¹ in France) that though all are tragic, only a very small fraction are widely or vividly reported. In contrast, almost any violence in Northern Ireland may be widely and vividly reported because of the concentrated attention on events there.

Reluctance to come

A melancholy way in which the troubles have affected scientists in Northern Ireland is that people tend to be deterred from coming because they (or more often their wives or parents) are worried by the risks. The worry is not based on an objective appraisal of the risks such as I have attempted in the preceding section. It arises from repeatedly seeing Northern Ireland on television screens and in news items. People are indeed aware that these are, quite properly, highly selective. Nevertheless it is difficult to avoid becoming partly conditioned by them.

There have been cases of service engineers refusing to travel from Great Britain to Belfast and of firms putting such travel on a volunteer basis and being loath to renew maintenance contracts. The inconvenience caused has been of only a minor nature and any accompanying irritation has been amply compensated by the good conceit of ourselves induced by this display of lack of discernment and faint heartedness.

Table 4 Fatal accident rates R_A (per hundred thousand) in some advanced countries (1969 or 1970)^a

Country	R_A
England and Wales (1970)	35.3
Northern Ireland (1970)	39.4
Japan (1970)	41.8
Republic of Ireland (1970)	42.9
Scotland (1970)	43.3
Sweden (1969)	43.3
Holland (1970)	49.4
Denmark (1969)	50.4
United States (1970)	54.1
Canada (1969)	55.4
Australia (1970)	55.6
New Zealand (1970)	56.4
Switzerland (1969)	58.2
Federal Germany (1969)	62.0
Belgium (1969)	66.0
France (1970)	74.3
Austria (1970)	78.5

Because of the troubles, a few university teachers have declined invitations to act as external examiners. The odd oral for a PhD candidate has had to be held outside Northern Ireland. Some external examiners have made enquiries about insurance cover while in Northern Ireland. Many have been apprehensive before their first visit. Feelings of apprehension, although unjustified, are entirely understandable and those who surmount them merit mild cossetting.

No difficulty has been found in getting visiting speakers for departmental research seminars. The practicality of holding major conferences here, however, has been uncertain. The Departments of Applied Mathematics and Theoretical Physics and of Pure and Applied Physics for example, obtained possession of attractive new buildings in September 1972. The five professors directly concerned had originally planned to mark the event by inviting the Institute of Physics to have its National Atomic and Molecular Physics Conference in the new buildings. But because of the disturbances they feared that attendance might be poor (though they did not doubt that distinguished invited speakers would come); and they decided unanimously to postpone the invitation. Perhaps they were over cautious. Certainly the Biochemical Society of London held a successful meeting here recently.

The Department of Zoology has observed a sad change in the willingness of groups to visit Northern Ireland. Before the troubles it established a Marine Biology Station near the entrance to Strangford Lough in County Down. A rich and varied fauna may be studied with the aid of the modern well-equipped fishing boat, the ecological diversity being unusually great because of the marked difference in exposure between the shores inside and outside the lough. Laboratory and residential accommodation for about 40 people is available and these excellent facilities were being enjoyed to an increasing extent by groups from other universities. That has virtually ceased.

Yet the Marine Biology Station is set amidst peaceful surroundings.

The most serious problem is presented by the number of students entering the Faculty of Science. In 1966 Queen's University, which from its opening in 1849 had remained an essentially local institution as far as its undergraduates were concerned, began to participate in the Universities Central Council on Admissions (UCCA) scheme in recognition of the fact that a considerable fraction of undergraduates both prefer, and are financially enabled to study away from home. An example illustrating the extent of the scholarly migration is that in October 1969 more than 25% of all entrants to the universities in the North-Western region of England (those in Lancaster, Liverpool, Manchester and Salford) were domiciled in the South-Eastern region⁶. Life in Northern Ireland had (and still has) much to offer, being engagingly (though alas now also agonisingly) different from life in England. In 1966 it did not seem unreasonable to expect that many students would elect to cross the Irish Sea and, indeed, by October 1968 the number entering the Faculty of Science from outside Northern Ireland had risen to 15% of the total. The troubles led to a drastic decrease in the inflow of students (and to some English students withdrawing at the insistence of their parents). Meanwhile the outflow, already substantial, continued to increase. Because of the imbalance the number entering Queen's Faculty of Science fell by 19% between October 1968 and 1973 whereas the number entering all faculties of science in the UK rose by 12% during the same period⁷. A turning may have been reached. Analyses of the UCCA application forms received by the end of June 1974 and June 1973, suggests that (against the national trend) the faculty may have more entrants in the coming academic year than it had this year.

The position regarding postgraduate students is happier. Between the academic years 1968-69 and 1973-74 the number in the Faculty of Science increased by 18%. This is actually 6% more than the corresponding increase in the total number of postgraduate students supported by the Science Research Council⁸ (which presumably provides a guide to the pattern in Great Britain).

Recruitment of staff is not easy. Fewer applications are received than for similar posts in other universities of the same standing and the practice of personally inviting applications from strong potential candidates has become less infrequent. The applicant who is offered an appointment occasionally states that he himself is eager to accept but that before doing so he must get the agreement of his wife who is worried at the prospect of living in Northern Ireland; and he may later have regretfully to write with the information that he has been unable to persuade her. The Board of Curators responsible naturally takes a long term view of the interests of the university and prefers to leave a temporary vacancy rather than make an appointment which is not fully satisfactory. A grave situation might have developed had it not been for the shortage of academic posts in Great Britain and the United States.

Carrying on

Some of the staff of the Faculty of Science have felt impelled to take part in communal or political activities—one (an applied mathematician) even ran successfully for election to the Northern Ireland Assembly. Their public spirited endeavours have inevitably been at the expense of their researches.

But what about the others, the great majority? I have asked many whether their researches have been affected by the troubles. All immediately replied that they have not and most seemed rather surprised by my question. A few expanded on their answer. Two added that any stress in life here is much less than the stress they had endured from commuting in London. Another, commenting introspectively on how little he was really disturbed by the sound of an explosion in spite of knowing that a tragedy may have occurred, said that except for a surge of anger his reaction was mainly transitory curiosity such as he

might experience on noticing a speeding fire engine anywhere.

An objective (if objectionable) check on the validity of the opinion expressed on research can be obtained by comparing the number of journal publications per faculty staff member which are based on research likely to have been done during the first three years of the present troubles (the latest years known) with the corresponding number for the preceding 3 years. The former is less than the latter by 5%, which is not significant, being within the possible percentage error in either of the two numbers. Again, the computer power used in Queen's University has risen through the years of the troubles at almost precisely the same rapid rate as the total computer power used in all universities in the UK.

The staff of the faculty work and live in relatively safe areas. It would be odd if they let their researches be impaired in view of the resilience shown by much less fortunate fellow citizens. Traders whose premises are blasted soon put up 'Business as Usual' signs; factory workers have helped make possible the 23% increase⁹ in the Index of Industrial Production for Northern Ireland between 1969 and 1973 (which is rather greater than the 15% increase for the UK as a whole).

Evidence on the extent to which life here continues much more normally than people elsewhere seem to think is provided by the fact that most of our graduates still prefer to take up employment in Northern Ireland: on average 77.5% of those graduating in the academic years 1968-69 to 1972-73 did so as compared with 73.1% of those graduating in the academic years 1964-65 to 1967-68.

There is little which need be said regarding teaching. Some changes have been made in field work; for instance the Department of Geology judged it imprudent to continue to use a mountainous area just across the border with the Republic of Ireland, which it favoured before the troubles, because guerillas are now reputed to train there. Other geologically suitable areas are readily accessible. The Department of Geography has also modified its field work pattern—not as a consequence of any incident but to ensure that the risk of one is remote.

Members of the staff in charge of field work have unexcelled opportunities of getting to know their students really well. Those I have spoken to have not noticed tensions between the students nourished by our two different traditions. The student body as a whole has displayed a remarkably high standard of responsibility.

The undergraduates seem to have become more serious and to be working harder. Table 5 shows the number of those in the Faculty of Science who in a particular academic year leave without a degree expressed as a normalised fraction f of the number of those who graduate (the normalisation factor being chosen to make f for 1968-69 have the value unity). As may be seen f has been declining steadily through the troubles.

Table 5 Number of undergraduates leaving the Faculty of Science without a degree expressed as a normalised fraction, f , of the number of those who graduate in the same academic year

Academic year	1968-69	1969-70	1970-71	1971-72	1972-73
f	1.00	0.85	0.78	0.76	0.72

Examinations are particularly vulnerable to deliberate or casual interference but the troubles have had only a minor effect on those in the university. In June 1972, a chemistry examination was disrupted by a bomb hoax. Another examination was quickly arranged. This was done easily because the question paper for the supplementary examination to be held in September (for the benefit of candidates who failed) was ready. Since the disruption, security precautions have been taken in and around examination halls. These are so thorough that any hoax warnings can be ignored with complete confidence.

The aim of *Horizons in Biochemistry and Biophysics* is to call the attention of students, teachers, and practicing scientists in the biological and physical sciences, including medicine, to

- major conceptual and methodological advances and important discoveries in biochemistry and biophysics
- the need for re-evaluating widely accepted theories
- the possibility of applying discoveries to knowledge in other fields.

In order to ensure the wide readership vital to the concept of the undertaking, the initial volumes of *Horizons* will be

issued simultaneously in hardbound and in paperbound form. It is hoped that the relatively modest price for the paperbacks will allow individuals to enter *personal subscriptions*.

Volume 1, End 1974, about 350 pp., illus.;

hardbound ISBN 0-201-02711, approx. U.S. \$13.50;
paperbound ISBN 0-201-02721, approx. U.S. \$6.75

Volume 2, Spring 1975, about 350 pp., illus.;

Provocative and comprehensive — a look at the current status of cancer research

ARMIN C. BRAUN

(Rockefeller University)

The Biology of Cancer

This book was written not for the specialist but rather for the beginner who has acquired a background in the basic biological sciences and who is interested in gaining insight into our present understanding of the cancer problem. The biology of cancer is examined here in the broadest terms, and an attempt is made not only to identify the essential biological concepts that underlie the tumorous state but to critically evaluate as well the premises upon which prevailing thought in the field of experimental oncology is based.

"Cancer research quite understandably has focused very heavily throughout the past century on immediate causes and cures. This clinical approach to the problem has been of limited effectiveness, producing 'treatments' but no widely applicable cures. It might appear desirable to gain an understanding of the basic cellular mechanisms that underlie the tumorous state. . . . While an attempt was made in this general survey to cover, albeit briefly, most if not all aspects of cancer biology, emphasis has been

placed here on those investigations that appear most likely to provide insight into an understanding of that problem.

"This was done not only to stress the purpose and significance of pertinent studies that bear on these matters but, more important perhaps, to provide a conceptual framework for possible future investigations in this challenging and most important area of the scientific endeavor." — *From the Preface*

End 1974, about 180 pp., illus.;

V. K. MURTHY

(University of California, Los Angeles, and University of Southern California)

The General Point Process

Applications to Structural Fatigue, Bioscience, and Medical Research

No. 5 in the

APPLIED MATHEMATICS AND COMPUTATION Series

This book is concerned with the theory and applications of that process of events which occurs in succession, in time and in space, such as a straight line, a plane, and the three-dimensional space in which we live. ("Event" or "point" stands for the happening of a situation.) Examples of such events include an airplane experiencing sudden acceleration due to turbulence or maneuvering procedures, or a person suffering an acute myocardial infarction. The lapses in time between points or events, when time is counted

arbitrarily, i.e., not at the beginning of the happening of an event, is called a General Point Process.

The author's two prime objectives are to develop the theory involving the distribution of events by any specified time for a General Point Process and, also, to review the many fields of applications of this theory and to formulate their interrelations.

Pattern Recognition Principles

No. 7 in the

APPLIED MATHEMATICS AND COMPUTATION Series

This is the first textbook covering the entire spectrum of pattern recognition techniques ranging from the classical deterministic and statistical pattern classification methods to the more modern syntactic pattern recognition concepts. There is also detailed treatment of feature selection and extraction methods. The comprehensive coverage of these data and the material on syntactic pattern recognition are unique to this work, which stresses principles and is written at a level suitable for self-study. The material has been tested extensively in classroom use both at the senior and graduate levels in electrical engineering and in computer science curricula.

Numerous examples are included and problems are provided at the end of every chapter. An Instructor's Manual will be available.

"Pattern Recognition Principles" will be a valuable aid to engineers and scientists working in automatic information processing and related fields; it can also be adopted for classroom use in biomedical engineering, information science, electrical engineering, management science, and bioscience.

Biological Transport

Second Edition completely revised, enlarged, and reset

With contributions by **Dale L. Oxender** and **Gunnar Ronquist**
End 1974, xx, 514 pp., illus.;

hardbound, ISBN 0-805-32251-5, U.S. \$19.50

An up-to-date presentation of central aspects of molecular transport across biological membranes is now available in this completely revised edition. The parallel subject of group translocation is discussed. Here is a critical guide to the original literature for use by the advanced student of bioscience (biophysics, biochemistry, physiology). Investigators in these subjects and in microbiology, physiology, pharmacology, genetics, and other researchers working on membrane and transport will find the volume of special interest.

CONTENTS

A Survey of the Scope of the Problem of Transport • Membrane Composition and Structure • Thermodynamic Aspects of Transport • Kinetics in Transport • Effect of Solute Structure on Transport • Genetic Approaches to the Study of Transport Systems by **Dale Oxender** • Binding Proteins and Transport • Group Translocation • Structurally Bound Adenosinetriphosphate-Phosphohydrolase of the Animal Cell by **Gunnar Ronquist** • Transport in the Mitochondrion • On Mechanism and Energy Transfer in Transport: Some Provisional Models • Effects of Transport on Distribution of Ions and Metabolite Transport • Development and Regulation • Some Practical Considerations of Techniques in Transport Studies • Appendices: Terminological Considerations; Correction for Nonsaturable Migration? Illustration of Preparation of Solutions • References; Author Index; Subject Index.

Structural Stability and Morphogenesis An Outline of a General Theory of Models

Translated by D. H. FOWLER from the French edition, updated by the author

CONTENTS:

Introduction • Form and Structural Stability • Structural Stability in Mathematics • Kinematic of Forms; Catastrophes • Elementary Catastrophes on R^4 Associated with Conflicts of Regimes • General Morphology • The Dynamic of Forms • Biology and Topology • Local Models in Embryology • Global Models for a Living Being (Metazoa) • Models in Ultrastructure • The Basic Problems of Biology • From Animal to Man; Thought and Language • Mathematical Summary and Index.

November 1974, about 400 pp., illus., hardbound, ISBN 0-805-39276-0, approx. U.S. \$22.50; paperbound, ISBN 0-805-39277-7, approx. U.S. \$13.50

Review of original, French edition:*

"It is impossible to give a brief description of the intellectual impact of this book. In one sense the only book with which it can be compared is Newton's *Principia*. Both lay

out a new conceptual framework for the understanding of nature, and equally both go on to unbounded speculation. From Newton's book, as Truesdell says, 'our forebears learned how to use the concept of force given *a priori*'; and there can be no doubt that from Thom's will come an elaboration which will allow our children to use more precisely the concept of *catastrophe* that he introduces. Almost all of the speculation in the *Principia* has turned out to be hopelessly wrong, though it would be hard to say to what extent this prevented its being useful at the time. So the criterion for Thom's speculative applications must come from their stimulating character, without trying to prejudge their correctness.

"An English translation is promised . . . but the reader is advised not to wait so long to acquaint himself with a major intellectual advance of the century."

Particles, Sources, and Fields [In 3 Volumes] Volume 2: Electrodynamics

Here is the definitive statement of modern quantum electrodynamics. The topics discussed range from vacuum polarization, in a variety of applications, to the hyperfine structures of positronium and muonium, with occasional excursions into nuclear and high-energy physics. Based as it is upon the conceptually and computationally simple foundations of source theory, little in the way of formal mathematical apparatus is required, and thus most of the book is devoted to the working out of physical problems. All essential details are explicitly presented in these discussions. This book will be of interest and value to graduate students in all branches of theoretical physics, to

atomic, nuclear and high-energy physicists, to mathematicians concerned with physical applications, and to philosophers and historians of science.

Volume 2, December 1973, 480 pp., hardbound, ISBN 0-201-06783, U.S. \$18.50

Volume 1, 1970 (Particles, Sources, and Fields), vi, 425 pp., hardbound, ISBN 0-201-06782, U.S. \$16.50

Volume 3 (continuing coverage of Electrodynamics; Partial Symmetry), in preparation

(University of Arizona)

Laser Physics

This volume treats the interaction of radiation with matter paying particular attention to the laser. Because existing laser media are intrinsically quantum mechanical and are most easily studied with the quantum theory, this book not only uses quantum mechanics but enlivens the reader's understanding of the subject as well. As a result the material constitutes a viable, applied alternative for the usual second and third semesters of quantum mechanics. The

reader will obtain from this presentation not only an increased understanding of the laser, but a more profound comprehension of many-system physical phenomena as well.

Ready Fall 1974, about 400 pp., illus.; hardbound, ISBN 0-201-06718-8, c. U.S. \$22.00; paperbound, ISBN 0-201-06719-6, c. U.S. \$13.50

The recent general strike organised by the Ulster Workers' Council took place during the examinations. During the fortnight it lasted, 12,464 examination seats were to have been occupied. Only 35 were vacant because of the strike. On the day, May 20, on which travel was most rigorously curtailed the corresponding numbers were 805 and 8 respectively. Some candidates had to walk long distances; some were under severe strain. Contrary to expectation, however, the general level of performance does not seem to have been lowered.

By ill luck, the printing of the question papers, delayed by the three-day week imposed because of the miners' strike, had not been completed when the Ulster Workers' Council strike was decreed. For a few papers, manually operated typewriters had to be used to cut stencils and these had to be run through manually operated duplicators. That I should mention such a prosaic affair is itself a revealing final comment.

I thank numerous colleagues for their generous help. Professor F. J. Smith, Director of the Queen's University of Belfast Computer Centre, provided information on the rise of computer power.

Contrasting styles of social responsibility

John Hall

Social responsibility in science manifests itself in completely different ways in Britain and the United States. In Britain the emphasis is on words, whereas the American approach is based on deeds.

A DIVERTING and not entirely misleading illustration of Old World and New World attitudes to social responsibility in science and technology is contained in the following two exchanges. The first features Art Tamplin, one of four resident scientists engaged by the Natural Resources Defense Council (NRDC) in the United States, who, when asked what his agency is doing as protector of the environment, reaches for a list summarising 100 lawsuits and related activities undertaken by 14 NRDC lawyers during the first four years of its existence.

The second exchange takes place at Fortress House, Savile Row, home of the 150-year-old British Association for the Advancement of Science (BA), where the avuncular Secretary and sometime television personality Magnus Pyke throws up his hands and exclaims that one must be truly ignorant if one does not know already about the association's activities in the region of social responsibility. He then lists categories of BA activity, which include a meeting of members in Scotland, meant in some sense to introduce science to the nation, the consideration by members of the effects of science on the body corporate, and the organisation of working parties in which experts consider specific problems.

But earnest consideration apart, one asks, what is the BA actually doing, for example, in the area of environmental protection? Two or three operations are going on, concedes Secretary Pyke, centred on universities, and employing the services of groups of schoolboys acting as 'information agents'. What does this involve? "Well, they can run out and collect sediment, and seaweed, and so on. Rather like winning battles with the Pioneer Corps."

Contrast

The comparison is not made in an uncharitable spirit, but simply to offer broad paradigms of British and United

States responses to similar problems. In Britain the tendency is first to define and discuss the problems, possibly (but not necessarily) hazarding recommendations, after which one might publish abroad the findings of one's working party in the hope that somewhere in the course of the democratic process attention will be paid to the deliverances of one's eminent panel. Actively engaging a problem, head on, is not a popular tactic. The favoured approach assumes that the good sense and standing of the working party's members is recognised outside their academic sphere of influence by, say, an Energy or Environment Minister, who on the one hand might have read politics at Ruskin and on the other might have flunked classics at Balliol.

In America a socially concerned science group is more likely to reach for its lawyers or take a government agency by the throat as a first line of defence against malfunctioning technology; education, study-group organisation and publishing are likely to constitute a continuing but secondary strategy. The Old World approach is to deal with conundrums raised by the possibilities of new science; the New World's is to regulate its confrontations.

Art Tamplin, Gus Spech, and Tom Cochrane (NRDC)

The self-help ethic and frontier spirit aside there are good business reasons for the different tactics: in the United States there are six or seven times as many lawyers as in the United Kingdom, and a contingency fee system which allows them to take something like 25 per cent of a client's damages if they win, and nothing if they lose. Since no similar sporting arrangement is allowed by the British legal establishment, there is little incentive for pressure groups and lawyers to join forces; over here the barristers can afford to win or lose, and their clients can't afford to do either.

This is not to say that the British system of organising committees to make sage deliverances is ineffective; but since the main agencies operating in this fashion deal with generalised and long term problems rather than with questions of specific and immediate concern, there is less chance of establishing a casual link (or absence of a link) between the group's activities and the eventual policy line directed by the government of the day. Thus, if Professor Bodmer's working party on Social Concern and Biological Advances says, through the agency of the BA, that the government should be prepared to act in order to prevent the abuse of research on *in vitro* fertilisation, it is difficult for them to claim credit when the government does just that. It is not a singularly original recommendation to make in the first place, but even if it were, the working party could scarcely claim a copyright on the idea. The NRDC and the Scientists' Institute for Public Information, on the other hand, can quite clearly claim that the Atomic Energy Commission's \$5 billion liquid metal fast breeder reactor programme was brought to a standstill because of their objections: the Court of Appeals register for the District of Columbia says so.

The BA deliberately avoids such hand-to-hand combat and the taking of partisan lines on issues of the day. As Dr Pyke points out: "We're against instant wisdom. When somebody has just read about something in the paper this week, and they're marching down the street with banners on the subject, usually they're wrong, and puerile. The BA's approach, and indeed its main usefulness, is to make plain the issues and the facts of the issues; we're in the communications business." And the reason why it's wisest to present facts rather than taking sides, says Dr Pyke, is that a group of scientists is rather like the criminal classes, in that it represents a broad cross section of the community, with every variation of opinion and foolishness that this implies. "I've seen so many scientists make asses of themselves on their own time; there's no reason why they should do so on behalf of the BA", says the Secretary.

Accordingly, although the BA may set people to work at issues of concern to society—like the uses made of scientific innovations by the police, or the ethical and legal problems of biomedical advances—the combined pressures of arriving at a consensus, and of not 'taking sides' can result in findings which are unexceptionable to the point of being platitudinous. After studying police methods for recording and computer-banking information about individuals, a working party will say that "serious thought needs to be given to people's attitudes to the recording of information by which they can be identified"; or after studying the complex problems surrounding AID births, that "the status of children conceived through artificial insemination by donor needs to be legally defined". My milkman might have reached the same conclusions while sorting his change.

Influential

The only British group of any standing which goes gunning for issues of immediate public concern is Parliament's own Select Committee on Science and Technology, an all-party committee which, although it can do no more than call witnesses and make recommendations, has proved im-

mensely influential, not to say embarrassing, in the formulation of official policy on energy. Unlike some parliamentary committees, the science and technology group is not confined to a limited area of study; it has an open brief to investigate and report on whatever topic it thinks fit, and so it can offer a forum for all shades of opinion on issues which are the subject of imminent governmental action if it chooses.

This is exactly what it did when it heard last year that Mr Heath's government was strongly in favour of American light water reactors for the next generation of nuclear power production in Britain. By summoning its own series of expert witnesses it provided, in effect, a second-chamber debate on the issue. For although the only exchanges were conducted between each witness and the committee, the publicity given to the hearings encouraged witnesses to refer to the evidence of others, so that the proceedings developed very much along the lines of a debate.

The chief advantage that the select committee has over other social responsibility groups is that it has the full powers of Parliament "to send for persons, papers and records". In other words, if the select committee calls, you've simply got to attend, and when you're there you're obliged to talk. The practical difficulty the committee members face, of course, is knowing who has something to say, so that he can be summoned and obliged to say it publicly. During the nuclear reactor hearings, for example, Sir Alan Cottrell didn't actually step up and volunteer the information that he had doubts about the pressure vessel integrity of the American hardware. But a whisper was heard to this effect and he was invited by the select

Dr Jeremy Stone

committee to make public his reservations. Possibly they would have been expressed through departmental channels in the normal course of events, but if the select committee had not had its ear to the ground so that the vital evidence could be made public at a fairly crucial point in the debate, the outcome might have been less certain.

A further strength in the select committee's dealings is that its evidence is privileged. So, if you're called, say, to give expert evidence as an employee of the electricity supply industry, you can say with impunity precisely what you think about the way supply industry chiefs are running and planning the industry. For some witnesses, coercion to give evidence of this kind is a positive pleasure.

During the seven years of its hearings the select committee has helped to force the government's hand on various issues (including the creation of British Nuclear Fuels, the establishment of the National Nuclear Corporation, and the creation of a department dealing with population problems), and it has established itself as an irksome pressure group which it would nevertheless be difficult for any government to dismiss. It has had to walk the fine line between pricking a government's conscience and actually challenging its authority. Its overall aim, according to its Chairman, Arthur Palmer, is "to do solid work but not to take so long that our conclusions are out of date before they're reached, while at the same time not following fashionable issues to the extent that we're not taken seriously."

The remaining British groups lack both the Parnassian elevation of the BA and the exceptional powers of the select committee. Broadly, they concern themselves on the one hand with the ethical possibilities of new technologies, and on the other with fostering grassroots involvement to defend the proletariat against developments seen as harmful, and with the radicalisation of scientists to assist this counter-offensive. The first category is represented by groups like the Council for Science and Society (CSS) and the Science Policy Foundation (SPF), which operate a traditional learned working party/publishing machinery; the secondary category (unless you include broadly based groups like Friends of the Earth) is represented by a single body, the British Society for Social Responsibility in Science (BSSRS), which relies on a combination of proselytising and missionary expeditions. It is difficult to say which category is the least effective, since the groups variously claim that they deal in unquantifiable forces (ethics don't measure), they are relatively new (nothing to measure yet), or that worker involvement may in itself be progress, although its specific campaigns have been abortive (radicalisation doesn't measure).

Practical men

The Council for Science and Society was formed last year with the object of "promoting the study of and research into the social effects of science and technology, and of disseminating the results thereof to the public". A registered charity funded with £80,000 over three years from the Leverhulme Trust, its 43 members include the clutch of Fellows of the Royal Society whose eminent names are virtually *de rigeur* on councils of this kind, along with assorted lawyers, industrialists, moral philosophers, theologians and 'others'. The essential distinction between the functioning of the CSS and the BA, according to the council's moving spirit Paul Sieghart, is that the council operates with "men concerned with practical affairs", whereas the BA (Bodmer's group excepted) tends to think that a body of scientists can supply the answers. The founding of the council followed the publication in *Nature* of a paper by an inter-disciplinary working party convened by ex-mathematician and lawyer Sieghart to consider the scientist's social responsibilities. He was interested in the interfaces between the disciplines of theoretical

ethics and science—the areas where controlled experiments were out of the question—where, he says, it seemed that a gap was developing into which mankind might fall and which he was concerned to bridge. His working party felt that diffuse debate on the subject could be brought into sharper focus, and, to quote its literature, it sought to analyse what were the special social obligations of the scientists, and to devise some practical means for discharging them.

Its conclusion was that the primary need was for institutional machinery designed to identify problems in the field before they became acute, to stimulate well informed debate about them, and thus increase the time span for social decision making by the usual political process. Accordingly, the council is not a decision-making body, neither does it intervene in topics already well debated, or so far away as to border the realms of science fiction. Instead it "seeks to identify specific developments in science and technology whose social consequences lie just over the horizon, where no full scale debate has yet begun, but where intensive analysis of the actual and probable 'state of the art', and of the foreseeable social consequences can suggest a range of possible responses to those who will sooner or later have to take the necessary decisions".

Currently, working parties are discussing the standards to be applied and the procedures for applying them, in weighing 'acceptable risk' against anticipated benefits from new technologies; the use of surgical, pharmacological, psychological and other techniques for the control of individual behaviour deemed to be harmful or deviant; the problems involved in the development and use of 'harmless' weapons for the control of civil disorder; the problems posed to successful communication by the rapid growth in the volume of published technical information; the social and ethical implications of the nonclinical use of mood-control drugs; and the problem of monitoring technologies in those instances where technical competence is monopolised by a small number of institutions committed to the same interest.

The CSS will publish reports on each of these studies, outlining expected advances in the foreseeable future, the range of social consequences likely in the absence of controls, and the control mechanisms available if the consequences are to be modified. The overall aim is to arrive at an appropriate response "in the course of a responsible public debate conducted at leisure on the best information available, rather than by the hurried, ill informed and ill considered process which is apt to occur if the public does not become aware of the problem until too late in the day". Additionally, CSS makes itself available to government departments for advice, and apparently the appropriate departments have availed themselves of this facility already. On what issues? Confidential issues. Also, the council is available as confessor to scientists who have qualms about research projects they are working on. So far there has been one taker. On what issue? A confidential issue. The CSS probably has a rosier future than the BA in this area, because it engages younger, brighter people from mixed academic backgrounds, but for the moment there is nothing to measure but high intentions.

No criteria

The Science Policy Foundation (originally the Science of Science Foundation) has been operational since the middle 1960s, and has a similar difficulty in identifying its achievements, although in this case the claim is that there are no criteria for measuring the stock in trade: ideas, ethics, speculations. One thing abundantly in evidence at the SPF is a plethora of publications and eminent signatures in the guest book which also bears menus recalling the meals at which these eminents have taken their pleasures. The

Dr Jeremy Stone, outside the new headquarters of FAS

SPF looks like a one-man band, orchestrated by a former UNESCO science editor and *Reynolds News* writer, Maurice Goldsmith (although in fact he is answerable to a management committee). In 1964 Goldsmith was asked to edit a collection of articles to commemorate the 25th anniversary of J. D. Bernal's *Social Function of Science*. The collection was called *The Science of Science*, and after publication Sir Laurence Bragg, no less, suggested the formation of a Science of Science Foundation. No sooner was this said than done, with Mr Goldsmith at the helm, bearing a twin charter to look at science and technology internally in order to determine what were their growth mechanisms and to study the impact of science and technology on people.

To be fair, the SPF (the name changed because it became a bore to explain the meaning of the Science of Science at every turn) never actually undertook to do anything about social impact problems other than study them. In the event they have studied and published. Virtually everything the SPF touches involves a publication of some kind, and none takes a distinct line on a controversial issue. This is because the committee of management, which is another list of eminent names, covers such a wide spectrum of political views that no unanimous line emerges.

Two years ago the SPF set up a committee under Lord Avebury to take up contentious issues; the committee never reported. A similar committee was established to examine the Rothschild proposals for Government research and development; no agreed statement emerged, but the original report and the committee's deliberations over it were published, and sold. On energy the SPF takes the line that there is no need for an energy policy, but did not actually discuss reactor choices; on environmental pollution

it has made no statement, but, says Goldsmith, no member of the management committee would oppose the notion that pollution was a bad thing. Seminar fees, cash from publications, grants and donations roll in to the tune of £15,000 to £20,000 a year, and the prestigious dinner parties are entered in the book. "We do good by stealth," says Director Goldsmith, confiding that Cabinet Ministers receive "behind the scenes advice" at tables, where one may also find representatives of "key institutions", discussing things "pretty freely and off the record".

As a result of one *tête à tête* with Peter Walker (then Secretary of State for the Environment), Goldsmith and his colleagues at SPF were introduced to D. J. Lyons, Director General of Research Department of the Environment, and SPF was awarded the contract to publish the department's register of current research in the United Kingdom in the fields of town and country planning, environmental pollution, transport, building and construction. Not an insubstantial volume, but, says Mr Goldsmith, a non-profit making one.

Among the SPF's committees is one whose brief is to look at the foundation's terms of reference, with power to recommend that it be wound up if it is no longer a meaningful institution performing a useful function. The committee has never made such a drastic recommendation, although, says Goldsmith, if that's the way they feel, he hopes they will take the step. He adds that he doesn't expect this to happen while he is director.

The British Society for Social Responsibility in Science was formed at the Royal Society in 1969, with 40 Fellows among the founder members and a policy statement to which, it was said, the director of Porton could scarcely have objected. Most of the Fellows began to look worried when at the BA's 1970 meeting, the younger membership mounted a militant demonstration against British Army methods in Northern Ireland. A sort of Hippocratic Oath about scientists' moral responsibilities was taken by some members, and adopted as policy. Since then the society has agonised somewhat over its role and its political stance, and has emerged with a philosophy which says that moral oaths are pretty meaningless in a capitalist society, and that science is not simply a neutral body of knowledge, but a potent weapon for those who control it.

The abuses of advanced technology are not accidental, but spring from the nature of our society, says the BSSRS. Scientific and technical knowledge is "an important source of power, but only large institutions have the resources needed to exploit it. Advanced technology is used by our major corporations to create demand for new products, consumer or military. The government ensures, by economic management or direct intervention, that a market for these products will be found. . . . Thus science is used directly to increase the power of the already powerful and frustrate the expectations of the powerless". Naturally, the Royal Society Fellows are thin on the ground by now, but nobody at the BSSRS minds all that much, since, with the odd exception, Royal Society Fellows were found to be unwilling to do much more than lend their names to letterheads.

In terms of hard cash and administrative machinery the BSSRS looks distinctly shaky; its original Rowntree grant of £3,000 is almost spent, with no likelihood of renewal; membership stands at no more than 700 or 800; the society exists by courtesy of a largely part-time staff; and the £2,000 which it receives each year from endowments can be used only for educational purposes. Its office, also owned by Rowntrees, may not be available for much longer, and the work force is thinking of running the society as a collective. And yet these straightened circumstances, which might be the kiss of death to a traditional seminar/publishing-based body, organised on a centre-periphery administrative model, are less likely to kill a

loosely structured organisation like the BSSRS. It aims to develop an understanding of the social roles and functions of science and technology among people who do not normally expect to be consulted on such matters—the workers to whom its magazine *Science for People* is addressed—and its existence depends more on a network of grass-root operations than the survival of a central secretariat.

Already BSSRS scientists work in a consultative capacity with shop stewards' committees, mainly on issues like the toxicity or noise pollution of industrial processes—the strategy is to encourage people affected by technological nuisance to confront the problem themselves, with BSSRS supplying scientific expertise which the workers lack. They precipitated a strike by members of the National Union of Mineworkers over air pollution at a Coalite plant in Doncaster, action by a tenants' association attacking the plant responsible for the famous Battersea smell, and a strike by postgraduate workers at Edinburgh University which resulted in the raising of demonstration fees.

Urban collectives operate in Sheffield and Edinburgh, and autonomous BSSRS groups are active in half a dozen universities, beavering away at another favourite proposition of the society—that a non-elitist general education must emphasise the social implications of science and technology, and break down their isolation from other studies. All in all, the BSSRS might not be able to claim many successful campaigns against industry, but it can claim to have kindled community involvement, which is a success in itself, and it can only be a matter of time before its activities attract a grant from the Trade Union Congress.

Wide choice

In the United States there is an embarrassment of riches in the field of public interest science. An entirely arbitrary selection from the groups operating out of Washington yields the following bodies:

The Center for Science in the Public Interest (CSPI) operates a community involvement programme with aims similar to those of the BSSRS; the only difference is that it is more professional and more successful. The strategy is to introduce aggrieved citizen groups to experts capable of putting the finger on suspect planning decisions or industrial processes. Jointly with the public interest Economics Foundation, the CSPI has organised Professionals in the Public Interest, and come up with a meteorologist who helps groups to study air pollution from highways and power plants, an environmental engineer who is coordinating a survey of asbestos used in various consumer products, economists making evaluations of plans for interstate highways and cost/benefit analysis of public utility proposals, and a committee of scientists supplying community organisations with information on food additives.

The CSPI also has a healthy record running from asbestos to waste oil disposal, a list of 16 congressional and judicial testimonies last year, 48 administrative actions and requests, aimed at government agencies and individual senators, and two lawsuits, one requiring the Environmental Protection Agency (EPA) to reveal gasoline additives under the Federal Clean Air Act and the other attacking the EPA on asbestos, beryllium and mercury emission standards. Eleven major companies are opposing this action. The center's report on aerosols is thought to have cut market growth in that industry from 10% a year to 2½%.

This programme has been managed by a full-time staff of eleven, working for an average of \$360 a month, and a small army of volunteers. The CSPI started in 1971, with a staff of three working from a borrowed desk in the Oil, Chemical and Atomic Workers' office, and a budget of \$2,800 for the year. In 1972, the figure rose to \$19,600; in 1973 to \$39,600 and for the first nine months of this

year to \$72,600. Half of this money comes from the sale of publications and reports, the rest from foundations and donations.

Strategies, selected for the individual requirements of a problem, include the in-depth report, litigation, pamphleteering, citizen organising and what is known as the professional informational approach. Latest successes included an investigative report, *Interlocking Oil*, on the power of oil executives who also serve as bank directors and who manipulate instruments to drive out competitors. Using this study, several senators are writing legislation to eliminate these conflicts of interest. The CSPI also helped to organise a citizen's energy conference in Washington for 1,000 citizen activists from 47 states to develop strategies for increasing citizen power in the decisions on the uses and costs of energy resources.

The Federation of American Scientists (FAS) was founded in 1946 as the Federation of Atomic Scientists and is the country's only scientific lobbying body. It has a staff of three, eminent sponsors who include 29 Nobel Laureates, and a membership of 6,500 lawyers, doctors, engineers and scientists whose membership fees amount to \$90,000 of 'hard' money annually. 'Hard' money is tax exempt, but not deductible, and so it can be used for lobbying, whereas the 'soft' kind can only be used for education and publicity that does not attempt to influence legislation. The FAS tradition of lobbying started in 1946, when its briefings of congressmen helped to ensure civilian control of atomic energy. More recent successes have included an important role in holding up the building of an antiballistic missile system, and pioneering work on the promotion of scientific relations and exchanges between the United States and China (the People's Republic, that is).

Through its Director, Jeremy Stone, the FAS button-holes congressmen, gets them to listen to informed scientific opinion, and testifies at hearings. Its tax-deductible subsidiary, the FAS Fund, engages in research and educational functions, including the publication of a Public Interest Report which has taken strong lines on SALT 1, electronic eavesdropping, national science policy, research and development priorities, the Geneva Protocol on biological and chemical weapons, and the rights of Soviet scientists.

Stone (son of I. F.) has just toured the States trying to raise \$1 million from a few rich men in order to endow positions for three scientists, probably retired professors, to develop FAS staff expertise in the areas of environment, energy, medicine/public health, and development/population/food supply. According to the FAS the legislature hearings, although the heart of a publicly accessible debate over science and society issues, are often unattended by the press, and important laws get on to the books before alarms can be raised. The three new men will have the job of keeping an eye on such hearings, and making prompt reports, apart from providing briefings in their special fields at regular intervals.

The FAS, which calls itself the voice of science on Capitol Hill arranges two-way information exchanges between politicians and scientists, feeds congressmen's aides with intellectual grapes for scientific debates, and generally fixes things so that legislators do not make policies in areas whose workings they do not fully understand, without being fully aware of the alternative consequences. "We take positions on which reasonable men can hardly differ," says Stone. "We can't take eccentric lines; when you're going to Congress you've got to find the least common denominator".

The Natural Resources Defense Council, Inc., has a budget this year of £1,845,000. It employs four full-time scientists and 14 lawyers. It is four years old, and has a staff of 60 people working from headquarters in New

York, Palo Alto and Washington. It is the largest and most effective environmental law agency in America, and was founded to provide legal counsel to citizens and organisations seeking to protect the environment; to take legal action to protect the environment on its own initiative; to monitor the performance of government regulatory agencies whose activities affect the environment; and to encourage the legal profession to play a greater role in defending the environment.

In deciding whether or not to help citizen groups to find legal redress beyond their means in order to protect the environment, the NRDC uses two criteria: first, that the potential for establishing a legal precedent exists, and second, that without the NRDC's help, some valuable or unique environmental resource will be destroyed. Through

its recent actions it has saved for the time being much of the country's existing system of railroad track through a test case against the Interstate Commerce Commission, blocked the Atomic Energy Commission's liquid metal fast breeder reactor programme, forced the EPA to issue its standards on atmospheric lead standards, won a decision which challenged the clear-cutting of trees, sued to change the utility rate structures favouring big industrial users (granted by public utility commissions), opposed strip mining, offshore oil drilling and noise pollution in cities, and successfully petitioned the EPA to stop the use of four lethal poisons used by the Fish and Wildlife Service for predator control. To understand the full weight of the NRDC's effort you have to read the book listing its legal actions.

Murder involving discovery and first application of fluorescence of tyre prints

J. H. Loughran,

Warwickshire Constabulary Headquarters, Leek Wotton, Warwickshire, UK

J. B. F. Lloyd and T. R. Watson

Home Office Forensic Science Laboratory, Gooch Street North, Birmingham 5, UK.

Details are given from a murder investigation in which the fluorescence of tyre prints was discovered. The prints enabled the tyres and the vehicle in which the body was carried to be identified and fluorescence spectroscopy demonstrated a correlation between the fluorescence of one of the tyres and the corresponding print. Circumstances favouring the formation of fluorescent prints and the importance of the technique for forensic science are discussed.

PART of the evidence for the prosecution in a recent case of murder arose from the discovery by the investigating police officers of a set of fluorescent tyre prints. In our view the discovery will initiate developments of widespread significance to forensic science. We wish to describe, therefore, the circumstances of the case so far as they bear on this striking and hitherto unrecognised phenomenon.

The pertinent facts established in the enquiry, and subsequently accepted by the defence were that on the evening of Saturday, July 7, 1973, a Mini Estate vehicle, apparently deliberately set ablaze, was discovered in a field off Glasshouse Lane on the outskirts of Kenilworth. Immediate enquiries revealed that the owner was a local person, whose elder son, last seen that morning, proved to be missing. The son's bedroom and other parts of the house were heavily bloodstained. The investigation was therefore pursued as a case of murder, to be justified 5 days later in the discovery of the youth's body on a rubbish tip.

The parents of the youth had left home early that Saturday morning. At 0730h his younger brother was collected by a John Lees, who employed youths at weekends to assist in his work as a driver and labourer for a building company. Lees took the younger son to a building site, gave instructions on the work, and returned to the house, where he battered the still sleeping elder son to death. The body was rolled in the bed sheets, removed downstairs to the garage and into the family's Mini Estate vehicle, which was driven to a building site at Albion Street. Lees parked the car in number five of a newly completed and cleaned row of garages which he had worked on. That evening he drove to the tip, dumped the body on the tip face,

and covered the body with rubbish. He finally left the car ablaze in the field off Glasshouse Lane, and departed from the area. On his return 10 days later he was arrested, and subsequently, on January 21, 1974, at Birmingham Crown Court, pleaded guilty to the murder. He was sentenced to life imprisonment.

Our report concerns the Albion Street garage. Three days before the discovery of the body, when the movements of the car and any connections with Lees were crucially important matters, a bloodstained axe and a mutilated wallet belonging to the deceased were found close to the garages. There followed an inch-by-inch search that revealed in garage number five a small oil spot at the point expected had a front-engined car been reversely parked there. The oil proved to be largely Duckham's 20W/50, matching by thin layer chromatography and by fluorescence and infrared spectroscopy, oil from the Mini Estate. Otherwise, nothing whatsoever remained on the apparently featureless concrete garage floor to identify or to indicate even vaguely the type of vehicle that had evidently stood there.

It was decided that the floor should be examined in ultraviolet light. This was done with an Allen's portable lamp, emitting mainly at 366 nm, operated from a 12 V battery. Four brightly fluorescing tyre marks were revealed. (Figs 1 a and b). The precise definition of the marks enabled accurate measurements to be made that indicated, for the car concerned, a front track width of 122 cm, a rear track width of 117 cm, and a wheel base of 213 cm. Only Mini Estate vehicles correspond in these dimensions, for which the manufacturers quote 121, 116, and 214 cm respectively. The tread patterns reproduced in the marks are unquestionably of Goodyear G800 tyres at the front, and of Kelly Springfield KRI tyres at the rear. The burnt-out Mini Estate carried these makes of tyres in the same positions. These results, together with the matching oil samples established a vital link in the chain of evidence.

Part of the front near-side mark and samples of nonfluorescent concrete were chipped from the floor and removed to the laboratory. Before the examination of this material, however, experiments were made to determine the origin of the effect, which, it was found, can be readily demonstrated. When a tyre is contacted with a strip of polyester-backed thin layer chromatography adsorbent (silica gel or alumina) for periods

of as little as 3 min, fluorescence appears at all contact points. The fluorescence is blue-green in colour (with excitation at 366 nm), varies slightly in shade between different tyres and adsorbents, increases with time and pressure of contact, and reproduces the tyre pattern in detail. Analysis of the fluorescent material (by chromatography on the adsorbent *in situ* by spectrofluorimetry *in situ*, and by the latter technique and by spectrophosphorimetry after solvent extraction from the adsorbent) indicates that the fluorescence is caused by the transfer of extender and process oils, antioxidants and polynuclear aromatic hydrocarbons from the tyre rubber to the adsorbent. All these factors vary with the make and the use of the tyres (J. B. F. L., unpublished) but the fluorescence originating from most tyres in current use is caused mainly by extender oils.

Figure 2 compares spectra from chloroform extracts of prints from a selection of tyres (Fig. 2a). The spectra, partly quenched by this solvent to increase the detail resolved, were synchronously excited at an interval of 30 nm (ref. 1). The sensitivity of our equipment to ultraviolet fluorescence was low and therefore the emissions recorded are those occurring mainly in the visible region. The spectra clearly demonstrated, however, the extent to which fluorescence can vary with the originating tyre.

The nature of the receiving surface determines the intensity of the fluorescence obtained. Level, fresh adsorbent surfaces, concrete or brickwork, for example, have exhibited distinguishable prints within a contact time of 8 min. On soiled or aged surfaces, or where tyres have been in repeated contact, no distinguishable fluorescent prints are formed. Repeated contact either produces a diffuse area of fluorescence, or transfers so much ultraviolet absorbing material that all fluorescence is

Fig. 2 *a*, Synchronously excited (30 nm interval) fluorescence emission spectra of chloroform extracts from prints, on silica gel, of various tyre samples: *A*, Michelin X; *B*, Goodyear G8 remould; *C*, Goodyear G8; *D*, Pleak remould. *b*, Synchronously excited (30 nm interval) fluorescence emission spectra of chloroform extracts of: *A*, nonfluorescent concrete from scene after contact overnight with tyre from Mini Traveller; *B*, concrete from fluorescent tyre print found at scene; *C*, concrete-underlying that used in *B*; *D*, nonfluorescent concrete from Albion Street garage.

Fig. 1 *a*, Tyre print fluorescence, rear offside position at the Albion Street garage; *b*, tyre print fluorescence, front offside position at the Albion Street garage. Illumination in both cases was with an Allen's 12 V battery operated ultraviolet lamp. Photographed with a 35 mm single lens reflex camera fitted with a Wratten 8 filter on FP4 film exposed 600 s at *f*/5.6 and developed in Acutol.

quenched. Even so, many surfaces lie between the extremes. Thus, in our experience, fluorescent prints are often apparent in concrete-surfaced public car parks. No prints occur on bituminous surfaces, but many others, even of glass, collect material that, although not visibly fluorescent, yields fluorescent solvent extracts. For instance, a tyre dirt mark on paper is not fluorescent, but yields fluorescent solutions suitable for spectrofluorimetric analysis on solvent extraction. The effect is due to the minute particles of rubber of which such marks are composed (J. B. F. L., unpublished). That rubbers are intrinsically fluorescent has long been known, but this fluorescence, which is entirely suppressed by carbon black in tyre rubbers, is not extracted by organic solvents².

The circumstances at the garage were clearly ideal to the observation of tyre print fluorescence. Experiments made with a vehicle parked in an adjacent garage indicated that within 30 min four marks became apparent, after 1 h the fluorescence was considerably intensified, especially where the more heavily laden tyres contacted. This intensification continued over 8 h when all the marks had become equal in intensity. No visible changes occurred after this time, although the continued transfer of fluorescent material over extended periods of time can be demonstrated by spectrofluorimetry of solvent extracts.

Figure 2 also shows spectra from the material collected at the garage and from the corresponding tyre (Fig. 2b). The top surfaces of the chippings from the mark were scraped to yield 10 mg of powdered concrete, an extract of which in chloroform (0.5 ml) gave the spectrum shown. Further fragments of concrete, from the new surface exposed, contained no fluorescent material, in confirmation of the expected superficial distribution of fluorescence. Fluorescent material from the tyre was collected on nonfluorescent concrete taped to the tyre surface overnight. The spectrum of the extract obtained is also shown (Fig. 2b).

The excellent agreement shown in Fig. 2b between the two fluorescences added further weight to the highly significant evidence already obtained. We feel, however, that these results and the observations we have described will be important in many other circumstances. Apart from the characterisation of parked vehicles, examples, some already applied (J. B. F. L., unpublished), include the transfer of rubber from car accessories in hit and run accidents, from shoe soles and heels in scuff marks, from erasers to erasure marks, from the rubber debris contaminating surfaces heavily exposed to tyre contact

to people and articles themselves in contact, and, indeed, from any item liable to shed traces of rubber or fluorescent rubber additives at a scene of crime.

We wish to thank Detective Inspector J. F. Bradley of the Warwickshire Constabulary for the photographs reproduced and for experiments made at the scene.

Objections to science

Stephen Cotgrove

School of Humanities and Social Sciences, University of Bath, Claverton Down, Bath BA2 7AY, UK

Professor Cotgrove discusses the view that science is not as objective as its adherents claim. He considers the misuse of science, especially the use of pseudo-science to justify social practices.

RECENT years have seen a spate of critical writings on science. Much of this is concerned with the uses and abuses of science. But, some of the objections go deeper, questioning the objectivity and neutrality of science. Indeed, the Brook report to OECD went so far as to express concern at "the world-wide culture of educated youth which is deeply concerned with ecological perspectives and . . . could conceivably even adopt anti-rational views and could become more influential in the next decade than our extrapolations suggest"¹⁻³.

Science and culture

A dominant theme in the attack on science is its threat to humanistic values. The penetration of the world views of natural science into contemporary culture, it is argued, has encouraged ways of thought which will have disastrous consequences for the future of humanity. Specifically, it is the mechanisation and mathematisation of the world view of nature which is attacked: "Our hypnotic enslavement to the numerical aspects of reality has dulled our perception of non-quantitative moral values; the resultant end-justifies-the-means ethics may be a major factor in our undoing"⁴. Such objections in their more extreme forms go so far as a rejection of the primacy of reason and rationality and the celebration of emotion, feeling and unstructured spontaneity in thought and action^{5,6}. It is with such objections of course that the prevailing youth culture is so sympathetic and which may have particularly important implications for the future of science.

Those who see great dangers in the implications of science for human values have therefore sought to bring to light the meta-physical and ideological assumptions implicit in modern science and thus to challenge its claims to special objectivity. Second, they have exposed the ways in which science has been used as a justification and legitimation for social and political policies (scientism), thus negating its claim to neutrality. It is to these issues that I now turn.

Mechanistic approach to nature

The nub of the debate is the argument that the influence of natural science on culture is to reduce man to mechanism. Post-Newtonian physics has all too successfully exorcised the ghost in the machine. In place of the 'primary' human experiences of taste, touch, sight, sound and smell, nature is now explicable to modern science only in terms of matter in motion, or more recently, forces and fields. So, the Baconian dream of mastery over nature for the "relief of man's estate" has been

turned into a nightmare in which science becomes the basis for the dehumanising not only of nature but also of man. In the last analysis, mind and human personality, purposes and values, freedom and dignity—all are reducible to matter in motion. Man too, as a part of nature, thus becomes the object of manipulation and control. The mastery of nature becomes the basis for the oppression and repression of all that is human.

The reaction, understandably, has been to challenge the hegemony of the mechanistic view in a variety of ways. A particularly powerful attack has emerged in recent years on the more simplistic positivistic views of science as being objective knowledge independent of human judgement. Some of this critique stems from historians of science who have investigated the actual process by which new theories come to be accepted in science. Distinguished scientists such as Medawar and Polanyi have similarly stressed the crucial role of personal judgement—the distinctive vision of the scientist who discovers a new way of looking at nature—often in spite of the facts. It is this crucial role of theory as a screen between the senses and 'reality' which makes science an essentially human and fallible activity, akin to artistic creativity in its higher reaches⁷⁻¹⁰.

Such a perspective opens the way to an exploration of the external factors which influence the vision of the scientist as he seeks to interpret the shadows dancing on the wall. Thus, for example, Dijksterhuis concludes, "The strong influence which Newton's religious ideas exercised on his scientific thought is revealed, among other things, in his belief in the existence of absolute space and absolute time . . . Compared with the mechanistic idea of impact as the only cause of a change in the state of the motion, there is a spiritual or animistic flavour about the idea of an incomprehensible force operating at a distance which does not seem out of keeping with an anti-materialistic philosophy of nature." Needless to say, Newton's use of the concept force was strongly opposed by many of the leading natural philosophers of his day precisely on the grounds that it was an occult quality and unmechanistic (ref. 8, page 487 and ref. 11, chapter 7).

As an extension of this line of argument, the objectivity of the contemporary mathematical view of nature is questioned by asking what it is in fact that we now know about? Modern physics is a far cry from the attempts to understand nature in terms of the primary qualities ascertainable by the five senses. "Modern physics is not really concerned with 'things', but with the mathematical relations between certain abstractions which are the residues of vanished things . . . All we do in fact know is that we read our instruments—the number of clicks in the Geiger counter, or the position of a pointer on a dial—and interpret the signs according to the rules of the game . . ." (ref. 4, page 544). The 'facts' of nature are whatever meaning we can give to the readings on the dials. Or, as Bertrand Russell has succinctly observed, the only thing we know about the physical world is its mathematical properties.

Such observations then are used to support two main conclusions. Firstly, it is claimed, simplistic notions of the objectivity of science cannot be sustained. Galileo's view that "... the conclusions of natural science are true and necessary, and the judgement of man has nothing to do with them", is decisively rejected. Secondly, the limits and limitations of scientific knowledge are stressed. 'Certainty' is bought at the price of losing a massive amount of information and 'knowledge' of nature in the search for mathematical models.

Perhaps the weakest aspect of the challenge to the overriding dominance of the mechanistic view is its practical success, and the absence of any satisfactory notion of an alternative science. Here, the opponents of modern science turn to the recent history of science for examples of the way in which alternative views may exist side by side, each consistent with the known data. For example, Hesse shows that not only were theories of continuous action and action at a distance both equivalent in form and identical in experimental content, but both contributed to advances in electromagnetic theory (ref. 11, pages 216-222). It is argued too that alternative 'organic' views of nature have had some success in science. In the eighteenth century the divide between science and the humanities had not yet occurred, and speculation in natural philosophy embraced not only the experimenters but also poets and philosophers in its discourse including men like Shelley and Coleridge who turned to 'science' to combat the materialist mechanistic view. By contrast, they emphasised those aspects of science which stressed the unity of nature, the primacy of force over matter, and the unity of all forces. This Romantic viewpoint had an important influence on many scientists and in fact played a major part in the emergence of concepts of energy, and in many specific discoveries including the connection between electricity and magnetism, and Davy's discovery of potassium. In other words, an alternative paradigm free of the humanistic shortcomings of the mechanistic view has proved of value in the past and may do so again¹².

Reductionism and holism

Although modern physics is essentially reductionist, it is in biology where the feud between reductionism and holism has been fought with all the ferocity of a theological dispute. Monod, for instance, refers tersely to "a very stupid and misguided quarrel, which merely testifies to the 'holists' total lack of understanding of scientific method..."

Although some of the protagonists dismiss the attack on reductionism as a return to vitalism, in essence, the debate is about whether we can explain the properties of complex phenomena solely in terms of the characteristics of the parts of which they are made; whether that is to say, there are emergent properties of systems that are not discoverable simply from an analysis of their components. The debate can be examined at two levels. Firstly reductionism can be tested like any other theory (or perhaps meta-theory) for its explanatory power. Secondly, and what is perhaps more interesting, the ideological undercurrents and implications can be identified.

The case against reductionism is explored intensively and extensively in *Beyond Reductionism*, the report of the Alpach Symposium at which a group of distinguished scientists explored the growing criticisms of much biological orthodoxy, and the 'robotomorphic' mechanistic view of man implied in behaviourist psychology. Weiss, for example, drew attention to a number of difficulties in the reductionist position. Analysis, he argues, by focusing on smaller and smaller parts, inevitably results in the loss of information, notably information about interaction between the parts. It is in this neutral sense, he maintains, that the whole is greater than the sum of the parts—that is, what is discovered and recorded about the parts by the process of analysis. What is lost is information about the orderly relations among the parts. We need, he argues, to take account of the regulatory and controlling mechanisms which are to be found in the larger systems of which the subsystem is a part¹³.

By contrast, Monod's reductionist emphasis looks at first sight to be dramatically opposed. This is in part a reflection of the fact that Monod's emphasis and examples focus strongly on the base of the hierarchy—on the regulatory mechanisms of DNA and the genetic code. But on closer examination, Monod's descriptions look less unlike those of Weiss despite the very different positions each have taken in relation to reductionism. Monod too speaks of microscopic systems, and of "the cybernetic system of the simplest cell", and "that all activities that contribute to the growth and multiplication of that cell are interconnected and intercontrolled..."¹⁴. Monod too recognises that much remains to be demonstrated. But he decides as it were, to back a different horse.

It is highly probable that the issue will be resolved by further advances in microbiology. It is in any case an internal debate which will have to be left to the biologists to resolve. But of particular interest are the wider issues raised by the debate. Why, for example, are the protagonists so ready to accuse each other of such heresies as being unscientific, and so quick to identify the dogma in their opponents' positions? Both would seem to admit when pushed that neither position is dogmatically tenable and that the case is essentially unproven. For example, Commoner claims that the term 'central dogma' is often used in the literature on DNA. He quotes the opening comments of the chairman at the annual meeting of the Federation of American Societies of Biology (1965) as saying: "Let me review quickly the essential doctrines which comprise the dogma of modern genetics", and a participant as saying: "The reason we call this 'dogma' is that it depends on personal bias, not logic"¹⁵. Why then, if the tentative nature of theory is recognised, the impassioned partisanship?

Neutrality and commitment

In one sense, some measure of partisanship among scientists is what we would expect from what is now known about the process of discovery in science and especially the role of theory. But there are dimensions of this particular debate that are of special interest. For example, Monod has a section "dangers of genetic degradation in modern societies". This is the familiar argument which has raged since Galton and Spencer, that natural selection has been suspended. Monod's reasoning is worth quoting in full: "... statistics, as everybody knows, show a negative correlation between intelligence quotients (or cultural level) and the average number of children per couple. The same statistics also demonstrate that there is a high positive correlation of intelligence quotients between marital partners. This is a dangerous situation, which could gradually drain the highest genetic potential into an elite, shrinking in relative numbers"¹⁴.

Now there are two observations. First, this is a breathtakingly partisan statement and vast oversimplification of the nature-nurture debate about the nation's alleged declining intelligence. But more central to this discussion the reductionist position favours the 'nature' side of the equation—emphasising genetic factors rather than environmental influences.

What is being argued here is that such beliefs are embedded in and exemplify a more general ideology or *weltanschauung* which can be typified very crudely as antiliberal, and tough minded. The existence of such clusters of beliefs and attitudes is now well documented¹⁶. I am not here referring to the kind of ideological issues which have been traditionally associated with the left-right dimension in politics, but rather with a cluster of beliefs and attitudes which cut across such a conception of a conservative/radical dichotomy: in simple terms, an individual's attitude towards 'the bomb', and a range of 'Home Office' humane and moral issues. Thus support for the extension of nationalisation is no indication of a person's attitude towards capital punishment or the sterilisation of sexual offenders, or restriction on immigration. So it can be argued that support for the reductionist position is the expression of a more deeply rooted tough-minded philosophy of life, which not only values tough, logical rigorous and possibly rigidly linear thinking, but

is prepared to follow such logic to its perhaps disturbing conclusions, and in this sense allows means to determine ends and logic to dominate values. It is the expression of a basically pessimistic (though possibly realistic) view of human nature, aware of the need for tough and disciplined measures to control man's wayward tendencies and to nurture man's tenuous hold on civilisation. So, it would be claimed, we have to face the facts of the basic inequality of human genetic endowment and devise educational systems based on a recognition of such facts.

By contrast, it is those who incline to the opposite position, have a basically optimistic view of man's nature, and who locate the frustrations to the full flowering of human potential in impoverished environments and repressive social institutions, who are likely to find the implications of reductionism disturbing. Indeed, it is precisely from such radical critics of society and from the basis of the liberal-humanist tradition, that the most vigorous attack has been mounted—including Roszak, Dubos, and Habermas. From such perspectives, reductionism is seen as an expression of the mechanistic Baconian approach to science which sees science as a source of domination and control over nature (and man), as distinct from the more organic perspective of understanding and relating to nature¹².

Science as ideology

It is when the findings of 'science' are used as the basis for rationalising and justifying particular economic and political doctrines (scientism)¹⁷ that scientists are most open to attack for their partiality. There is a long tradition of justifying inequality, conflict, hierarchy, domination and competition through crude applications of biological notions to social dynamics (ref. 3, pages 259–263; ref. 18). Indeed, it can be argued that while crucial uncertainties are part of the human condition, there is need for folk sciences functioning as ideologies to provide comfort and reassurance. Seen in this light, the new natural philosophy of the seventeenth century "with its disenchanted and dehumanised world of nature and its appreciation of closely controlled experience, itself functioned as a folk science. . . ." And the extent to which 'science' persists as the dominant folk science can also be seen in the resistance to psi-phenomena as possible evidence of the powers of mind independent of matter, which if accepted would constitute a threat to the contemporary world view¹⁹.

Such scientism has entered a new lease of life with the current intellectual revival of ethology and its popularisation through such best-sellers as Desmond Morris's *Naked Ape*²⁰, and the earlier work of Lorenz. Despite the claim of the blurb that this study is "objectively scientific", Morris's book is in fact both partisan and prescriptive. Man is essentially a primate, the argument goes, and "still follows fundamental patterns of behaviour set down by his hunting-ape ancestors . . . and there is no hope of quickly shrugging off the accumulated genetic legacy of his whole evolutionary past". For example, the fact that *Homo sapiens* has evolved as the sexiest of all the primates is used to explain the fact that "whatever obscure, backward tribal units are doing today, the mainstream of our species expresses its pair-bonding character in its most extreme form, namely long term monogamous matings". So monogamy is safe: it's all in the genes; "the space ape still carries a picture of his wife and children with him in his wallet as he speeds towards the moon".

Now whatever the case for or against monogamy or the biological basis of religion, or aggression, the gap between genetic codes and such complex behaviour is so wide as to require a remarkable leap of faith to discover the bases of social relations and religious beliefs in the macromolecules of the DNA code. The most serious objection of the critics, however, is not so much that such claims put the objectivity of science into question, but that appeals to nature or to human nature are basically conservative. As Reich²¹ points out, they are used

to shift the problem from the social to the biological sphere where nothing can be done about it. Those who are anxious to change rather than to conserve, to free man from outworn constraints, to pursue new heights of discovery and self awareness, are understandably suspicious of theories which underpin a kind of fatalism; and an acceptance of what has been seen as natural, inevitable and in this sense, right²¹.

It could be argued that the attack on science is largely misdirected. It is the extravagant claims made for science which have generated a backlash. However elegant (and powerful) the mathematical equation, it is as partial to claim totality for such an approach to understanding nature as is the total rejection of science by those terrified at the prospect of a world without poetry. But science can hardly be blamed if some of its enthusiasts attempt a takeover bid for human culture. And if some scientists have used science as a pawn to promote the kind of world they want, one beyond 'freedom and dignity', or in which biological imperatives replace the messy and untidy human search for meaning and purpose, then they must not be surprised if such 'unscientific' behaviour stimulates some non-scientists to mount powerful antiscience arguments.

But to single out science as the cultural base for oppression, repression and various inhuman and antihuman policies is to overlook the repertoire of elaborate legitimations and justifications, both religious and secular that human ingenuity has invented for historical excursions into domination. It is one thing to point to the fact (with some justification) that science is and can be an instrument of human repression and quite another to argue that it is a major dynamic force marshalling the human race like the Gadarene Swine to rush headlong towards the destruction of all that is civilised.

Whatever legitimate criticisms can be mounted against the behaviour of some scientists and against some of the more simplistic versions of the nature of science, it can claim to be a special kind of knowledge in the very limited sense that it has been spectacularly successful in building a consensus of certified knowledge, which goes beyond the subjective judgment of any one individual. Whatever may be the human failings of individual scientists, and whatever the enthusiasms of the individual for his own theory, the success of science may lie in the way in which it has collectively regulated and harnessed the passions of such individuals to the shared enterprise of advancing public knowledge without deadening the enthusiasm necessary to sustain the often intense commitment to a theory. What keeps the individual creative scientist from being swept away by his own enthusiasm is the institutionalised code of conduct, which ensures that his work is subject to the critical scrutiny of his peers. It is at this level that for all its faults and blemishes, science can claim to have achieved a remarkably high level of objectivity. It is this quality of scientific knowledge which commands respect. The critics of science who question the objectivity of a science increasingly involved in military and industrial applications may well have a point. Such developments could conceivably damage the mechanisms of quality control²² and lose for scientific knowledge any special claim which it may have. And the antics of individual scientists who parade their ideological preferences under the guise of scientific objectivity outside the controlling mechanisms of the community of science, similarly threaten the high standards of their calling.

Beyond its more routine and humdrum reaches, science is an imaginative and creative act: the attempt to construct a meaningful picture of nature. And this is a picture which is in a constant state of flux and periodically undergoes revolutionary changes whenever a creative genius sees a new pattern in the ambiguous dance of the flames in the fire—a picture which excites the imagination of his contemporaries and generates a burst of activity to test its explanatory power. But in the last analysis the result is the subjective conviction of fallible men. What is accepted as a scientific truth is what survives the negotiations and interchanges within the scientific community. Whether and in what sense we can ever know 'objective reality' is a philosophical question beyond the scope of this paper.

Science and works of art

J. Plesters Brommelle and N. S. Brommelle

The National Gallery, Trafalgar Square, London WC2N 5DN, UK

Over the past few years, considerable advances have been made in the application of scientific method to the conservation of works of art. Slow changes in paintings with exposure to light are still the subject of research but recent developments in the protection of outdoor sculptures are encouraging.

DESPITE much publicity about the intervention of science in the realm of art, comparatively few of the world's museums and galleries housing the fine and applied arts have their own scientific departments and the number of scientists engaged in this field is small compared with that of research workers on any subject of comparable breadth and complexity in universities or industry. Consequently, a particular technique or instrument may be available only in one museum laboratory in the world, not necessarily in Britain. The international scene in our special field of study is not densely populated and economic considerations are probably the limiting factor in the application of science to works of art.

There are three main areas of application: (1) examination to determine the physical and chemical composition of the object, the nature of past, present, and possible future deterioration and, on occasion, to aid dating or authentication; (2) conservation in the sense of providing the optimum environment to prolong the life of the object; (3) conservation in the sense of restoration, that is treatment of the object to repair existing damage or deterioration. Obviously all three are interdependent. For example, examination is a prerequisite of treatment and to return a treated object to an environment which does not minimise the risk of future damage is to nullify in part the benefits of restoration.

Paintings

European easel paintings, the kind seen in the National Gallery, London, and usually dating from about 1300 onwards and painted on wood panel or canvas, are a rather special category. Every component of the multi-layer structure which comprises a painting—wood, canvas or metal of support, ground or priming layers, pigment

and medium of paint layers, varnish or surface coating—can be subjected to scientific examination, and the layer structure itself merits close study. Although such examinations often aid conservation and sometimes research in art history, it should be stressed that the study of artists' materials and techniques is a proper subject in its own right.

Starting with the lowest layer of the picture, the support, identification by microscopical methods of the wood species used in panels gives an indication of the provenance of the picture, but little hint of its date. Carbon-14 dating, indispensable in archaeology, is not usually applicable to painting because of limitations of sample size and the small time-span involved, but an allied dating technique—dendrochronology, the measurement of annual growth rings of trees—has proved useful. First applied in Hamburg to panel paintings of Rembrandt and Wouwermans, the technique has been developed at the Research Laboratory for Archaeology and the History of Art at Oxford where a new reference curve for slow-grown oak has been compiled and measurements made on oak panels including paintings by Holbein and Rubens in the National Gallery and National Portrait Gallery¹. The quarter-sawn planks often had 200–300 rings. For pictures independently dated, the tree-ring date usually worked out to be the date of painting plus about five years for seasoning of the wood. Unfortunately the technique is unlikely to be extended to Italian panel paintings since these are mostly painted on poplar wood.

One of the most important developments has been in the identification of paint media which up to about 10 years ago could only be roughly classified. Gas chromatographic analysis, pioneered by the National Gallery laboratory² is now used in several other museum laboratories in various parts of the world to detect the fatty acids present in dried oil and egg films, the ratio of which indicates whether oil or egg was originally present and the type of drying oil. It was found, for example, that Piero della Francesca's "Baptism" was painted in egg tempera, but his "St Michael" in drying oil, specifically walnut oil. Occasionally different areas or even different layers of the same picture have different types of medium. For this reason it is as well to use some microscopical technique,

Virgin and Child by Pyrgotelis, Church of St Maria dei Miracoli, Venice. *a*, Detail before treatment, *b*, after cleaning and consolidation (carried out by K. Hempel, Victoria and Albert Museum, London, and G. Musumeci, Venice).

such as biological staining, on a paint cross section before analysis. Although ^{14}C dating is not generally used, detection in the United States of recent forgeries, even of late 19th century pictures, has proved possible by measuring the increase of ^{14}C in artists' materials—in this instance linseed oil—resulting from the atmospheric testing of nuclear weapons³.

Identification of pigments is still often done by well established methods of chemical microscopy, a less arduous exercise than it would seem in that the majority of artists' pigments in the past were simple compounds of metals such as oxides, carbonates or sulphides, or minerals or other crystalline materials having well defined particle characteristics and optical properties. Emission spectrography and X-ray diffraction have also long been used, the latter indicating the compound present rather than the elements only. The electron microbeam probe would be ideal for layer-by-layer analysis of the mounted paint cross section but its cost and complexity prevent its acquisition. Over the past decade we have been grateful to have occasional samples examined on instruments belonging to other institutions but a long run of coordinated samples is needed for significant results when buying or borrowing time on an instrument. That it can be done successfully is proved by a paper published by the Louvre laboratory on the scanning of sections of early Italian paintings⁴. Lacking an electron microbeam probe on the premises, the National Gallery has just acquired a laser microspectral analyser. The use of laser microspectrography in analysis of works of art was introduced in the laboratory of the Boston Museum of Fine Arts some years ago. In the apparatus now in London the laser is used to evaporate a minute amount of the sample, thereby forming a crater the dimensions of which may be varied between 10 and 100 μm . The firing of the laser is arranged to coincide with the sparking of carbon electrodes and the rest is emission spectrography.

All the above methods require removal of a sample, however small, so a non-destructive method of scanning the surface of the painting for elements is desirable. X-ray fluorescence analysis is an obvious choice, with hopes pinned on the energy-dispersive form. Even here the layer structure cannot be ignored for the primary X-ray beam may penetrate the uppermost paint layer with confusing results. Also the range of elements is greater than in, say bronzes or silver coins. Sensational in their possibilities are a whole range of analytical techniques based on the application of nuclear energy, again a facility not to be found in the museum itself. In the mid 1960s work was carried

out in both Delft and Munich on neutron activation analysis of trace elements of lead white. Results indicated variations not only with date but also with geographical location. In the United States autoradiography of paintings has been used to identify pigments, as has isotope mass spectrometry, and one method for dating lead white depends on measuring its natural radioactivity. It is an achievement in itself to have evolved or applied these techniques. One hopes that these will not be isolated experiments but the start of some serious data collecting. The Doerner Institute at Munich recently put out a paper in which the author had compiled a table of periods of use and terminal dates of artists' pigments from his extensive experience of analysing pigments from a vast number of pictures of different schools and dates, using fairly traditional methods. Simultaneously with analytical methods examination of paintings by X radiography, infrared and ultraviolet photography still goes on. A recent advance is infrared reflectography, developed in the Netherlands particularly for revealing carbon black underdrawing on white grounds. It involves the use of infrared light at a wavelength of about 2 mm and an infrared-sensitive television camera instead of infrared-sensitive plates or film⁵. The National Gallery in London now has such an apparatus. The need to control the humidity and temperature of the atmosphere in which paintings are hung, particularly wood panel paintings, was recognised as long ago as the 1930s, and the first fully air-conditioned room with humidity control, cooling, warming, dust filtration and removal of SO_2 was opened in the National Gallery in 1950 to house some of the most important panel paintings. Eventually all the west wing was air conditioned. Control of illumination took longer to gain acceptance. Now, in addition to having ultraviolet filters on all light sources, whether daylight or artificial, the visible light has been reduced to 150 lx. Obvious damage by light is fading of pigments and dye-stuffs but photochemical degradation of any organic component, whether medium, varnish or canvas, is also likely to occur. It is often assumed that after a hundred years or so paintings must have reached some sort of end point in the changes of colour they may undergo. There is no objective evidence for this assumption. In rare cases where part of a picture has been protected from light the contrast with the exposed part is alarming. Research has been going on in the National Gallery to find methods of recording very slow changes in colour of paintings. The recent acquisition of a reflectance spectrophotometer, designed for the purpose by W. D. Wright, is a significant step

The new electronics

Oertling + Cahn

We are pleased to tell you that Oertling have taken over the sole UK Agency for Cahn Instruments, of Paramount, California.

Cahn fill well a particular niche in the world of weighing: "Micrograms without tears" you might call it.

Whereas conventional micro-balances need special setting-up, special environments and a fair degree of operator skill, Cahn balances need none of this.

In fact, the most popular model has a handle on the top; you put it on the bench, plug it in, put a sample in the pan and get a direct reading, to sub-microgram accuracy, in a second or two.

All Cahn balances can give a BCD output either as standard or optional, so they can feed direct into on-line control or recording equipment.

In this they naturally complement the Oertling ETP40 electronic top-pan, also shown in this advertisement.

Oertling have led the UK in laboratory weighing for 130 years. With Cahn extending the range, the next few decades look good too.

weighing family

R100 Recording Electrobalance R

Top left, with weighing mechanism in the symmetrical glass envelope, control module alongside, and optional pen recorder (below).

High capacity, 100g.

Sensitivity, 0.5µg.

Rapid response, to weighing in vacuum up to 10^{-6} torr, or under controlled atmospheres, including corrosive gases.

With push-button range selection, push-button taring, a panel meter to read sample weight and weight change, and an automatic range extender covering up to ten chart widths.

A special RG version is also available with a large range of accessories for TGA, absorption work, magnetic susceptibility, particle size analysis, density measurement etc.

4100 Manual Electrobalance

This page, centre.

The most popular Cahn model; a direct reading micro-balance that can give a complete reading in a few seconds.

No wonder it's used for Lunar dust, air pollution samples, etc. etc.

Robust, portable and very easy to use.

Just put the sample on the pan.

Capacity, up to 2.5g.

Four weight ranges, 2mg, 20mg, 200mg and 10000mg.

Sensitivity on 2mg range, 0.1µg.

4-digit electronic display read-out, with 100% over-range, i.e. up to 19999.

Automatic decimal position, with no chance of misreading. BCD output for computer or optional Cahn printer.

Models GR M and G-2, without digital display, also available at lower cost.

DTL Toploading Electrobalance

Below.

A very versatile direct-reading balance with large three-digit electronic display.

Capacity 10g.

Sensitivity 0.1mg (0.01mg optional).

Two weight ranges, 100mg and 1000mg. 0-10 volt analog output for recorder or DVM, with BCD optional.

Up to 15 samples per minute can be weighed, in all kinds of hot, dry or adverse environments; once the sample is on the pan you can get a reading in as little as half a second.

Also available, as RTL, without electronic display.

Oertling ETP40

Opposite, bottom left.

The special electronic version of the celebrated Oertling top-pan analytical balance, developed from the ColD award-winning TP30.

Capacity 800g + 100g tare.

Sensitivity 10mg.

Scale range 100g.

Large 5-figure digital display, plus BCD output and optional 10-key mosaic printer (shown right of balance) to code samples with batch number, time, date etc. on paper record.

Currently used in fine chemical production, biochemical research, precious metal weighing etc.

Oertling sales staff are now giving special demonstrations of all Cahn equipment, on customers' premises, and Oertling maintenance engineers have been fully trained to give all necessary service.

A member of the Avery Group.

forward. The new extension to the National Gallery which is to open next year, will have temperature, relative humidity, sulphur dioxide and light levels automatically controlled and recorded by a data logger for future use, but there can be no cause for complacency while the east wing of the present building still lacks air conditioning.

Restoration

In the treatment of paintings science plays rather less part than is the case for other types of works of art, for example objects of metal and stone. Although it might make his task less hazardous and certainly more interesting, it is doubtful whether a knowledge of the mechanism of polymerisation of drying oils or the optics of paint films would enable a picture restorer to produce a visually satisfactory final effect in cleaning, retouching or varnishing a picture. There seems to be no substitute in this case for skill and experience. In the postwar years it had seemed likely that modern synthetic materials of a high degree of stability would replace the traditional natural materials used in picture restoration. This expectation was only partly fulfilled. In this country at any rate restorers often show reluctance to use as varnishes or retouching media materials which differ markedly in handling properties from those they are accustomed to, and this includes some polymers with otherwise desirable properties, for example polyvinyl acetate and some acrylic copolymers. For final varnishing many prefer the lower molecular weight polycyclohexanone resins despite the fact they have only a modest advantage over the natural resins in rate of discolouration; their handling qualities are, however, similar. On the backs of pictures modern synthetic materials are more frequently used, for example the non shrinking epoxy resin adhesives instead of animal glue.

Recently the standard treatment of canvas supports, that of sticking a new canvas on the back of an old and weakened one to strengthen it, has come under scrutiny. Lining of canvases dates at least from the late 17th century, the earliest adhesives being glue and flour paste, in this century frequently replaced by beeswax mixtures. Now in its turn the soundness of wax lining has been questioned and in April this year a three-day international conference met at the National Maritime Museum, Greenwich, to discuss lining techniques. Alternative types of adhesive were proposed, such as emulsions of vinyl polymers, and lining canvases of polypropylene or glass fibre were demonstrated. Also on show were improved types of vacuum hot tables which enable lining to be carried out without the heavy ironing previously needed. One of these had been designed at the Courtauld Institute of Art, University of London. Although no clear-cut resolution seems to have been taken in favour of any one method the conference was an opportunity for discussion of a rather neglected but necessary aspect of restoration.

For art objects, technical examinations has been directed towards problems of dating and authentication, supplementing the art historian's style criticism, and towards investigating details of structure, composition and condition. Those methods which supplement visual examination—optical microscopy, X radiography, ultraviolet fluorescence and infrared photography have of course been available for many years. Wet chemical analysis has been in use since the 19th century for metal objects. The methods of physical analysis, developed mainly since 1900 and particularly since the Second World War, are applicable as much to art objects as to those usually regarded as falling within the field of archaeology. They have been used more sparingly in museum specialising in post-classical material where there is still a certain reluctance to turn to scientific aids, particularly when sampling is involved.

Of the methods of absolute dating and the consequent possibility of authentication where stylistic evidence and details of provenance are insufficiently positive, three of the methods of the archaeologist are available: ^{14}C dating, dendrochronology and thermoluminescence. It is seldom feasible to use ^{14}C dating for art objects of comparatively recent date, while dendrochronology though applicable for example to the study of furniture and wooden sculpture does not seem so far to have been used for the former, and not extensively for the latter. Neither of these methods is in any case linked directly with the date of production of the art object. Much interest has been shown, however, in the technique of thermoluminescence (TL) for absolute dating and the detection of fakes in ceramic objects, this has been developed at, among other centres, the Research Laboratory for Archaeology and the History of Art at Oxford. The techniques were until recently of value mainly for dating pottery more than 500 years old. Advances since 1969 have extended the range to more recent times⁸. A study of authenticity of Italian Renaissance terracottas, in comparison with documented forgeries of high quality by a nineteenth century sculptor, has demonstrated the possibilities of solving problems of recent art history, though unfortunately not to the extent that the work of master and pupil can be distinguished. These methods have been used during the past few years for an extensive study of Chinese Tang dynasty ceramics (618–906 AD) with good dating results for genuine works and clear distinction between these and imitations.

Most of the physical methods of analysis of value in archaeological research find a use in attempting to solve particular problems in the decorative arts, though extensive studies of groups of objects of particular periods, districts or craftsmen, sufficient for making judgements for inclusion or rejection of doubtful pieces on analytical grounds, are rare. Moreover, comparison between analytical results from different institutions is often of dubious value because of differences in sampling techniques and absence of information on precision and accuracy. Of the methods available (which there is no space to list in detail here) X-ray fluorescence analysis, being non-destructive, is naturally attractive to the curator of valuable art objects, though the fact that it is less accurate than atomic absorption spectroscopy and that analysis is only of the surface layers of an object, which are usually of different composition from the body of the object, make its use less valuable, except for specific studies of superficial layers. Recent attention both in the United Kingdom and elsewhere has centred on the development of energy dispersive X-ray fluorescence spectrometers. Their increased sensitivity compared with crystal dispersion types makes it possible to use radio isotope sources or miniature X-ray tubes, thus imparting a degree of portability, and the multi-channel analyser greatly increases the speed of analysis. One form of this apparatus, the Isoprobe, referred to above in connection with paintings, and developed at the Oxford laboratory⁷ has recently begun operation as part of the York Glaziers' Trust Research Programme for studying the chemical composition of 12th century stained glass from York Minster. Most analytical methods require a sample such as a fine drilling from an unobtrusive part of an object, but the X-ray diffraction techniques described by Bimson⁸ for examining the crystalline constituents of soft and hard paste porcelain for authenticity or attribution requires a sample so small that the method could be almost described as non-destructive.

Environment

In a modern museum of the decorative arts, the tendency to display in one gallery art objects of every kind of a

particular period provides problems of environmental conservation over and above those of a gallery of paintings alone. The control of light levels, of vital importance for textiles, where both dyestuffs and their fabric substrates are damaged, is made difficult by the complexity of the 'visual problem' of local lighting for particular objects and reflections from show cases, so that disability glare factors impel the curator to call for light levels higher than the 50 lx generally accepted as desirable⁹. The problem of damage by light was first studied scientifically at the Victoria and Albert Museum (then the South Kensington Museum) in 1888. Studies relevant to paintings but also of general value have been made continuously at the National Gallery since the 1950s and experiments on the fading of textiles, begun at the Victoria and Albert Museum in the 1960s are continuing.

Requirements for temperature and relative humidity and the elimination of air pollution are broadly similar for most art objects even though the properties of particular objects may require localised conditions. For the general ambience the tendency, where it is possible, to install complete air conditioning is to recommend more complete elimination of pollutant gases, notably sulphur dioxide, than previously specified, and, particularly where textiles are involved, the elimination of a high percentage of grime in the submicron range (60% plus on test dust No. 1).

Turning to the many problems of the restoration of art objects, apart from those which require fine craftsmanship in repair work, specialists in the United Kingdom are taking part in notable developments in stone¹⁰ and textile conservation while close attention is being paid to problems of deterioration and protection of painted and stained glass¹¹. British workers are in the forefront of developments in these fields. One of these, the problem of arresting the decay of calcareous stone and marble sculpture (and more generally the stone of buildings), in modern industrial atmospheres was, as recently as 1963, declared to be insoluble¹². Consolidation treatment when the sculpture could be brought indoors was confined to wax impregnation. Deterioration out of doors is a consequence, still not fully understood, of the complex interaction of a more or less porous aggregate containing calcium carbonate, with water, carbon dioxide and sulphur dioxide together with soluble salts, including, in some situations, sodium chloride. If the sculpture can be brought indoors consolidation treatment is usually needed, in conjunction with cleaning. If the sculpture must remain *in situ* total loss of the object as a work of art must be expected eventually unless treatment is given. Recently, notable advances in treatment have been made and the prospects are now

brighter than in 1963. Consolidation inevitably involves impregnation with a material which enters the pores of the superficial deteriorated layers, preferably penetrating into or bonding with the sound stone beyond. Dutch and American investigators have been using selected epoxy resins, vinyl fluoride polymers and silicon esters and successful work has also been done with a solution of barium hydroxide and urea leading to the deposition of barium carbonate. A different approach has been adopted for external sculpture in Venice by English conservators¹⁰ who apply a monomer of trimethoxymethyl silane which penetrates easily and deeply into marble and polymerises with water to a hard cross-linked solid *in situ*.

In 1950 the late F. I. G. Rawlins, then Scientific Adviser to the National Gallery, announced in *Nature*¹³ the formation of a new international institute for the coordination and advancement of research in conservation. This was the International Institute for Conservation of Historic and Artistic Works of which he was Secretary-General for some years until one of us (N.S.B.) took over that post. The institute, which celebrates its 25th anniversary next year with its sixth international congress, in Stockholm, has its headquarters in Trafalgar Square, London. Its quarterly technical journal, *Studies in Conservation*, first published in 1952, contains original work and reviews on advances in conservation and restoration. This with its *Art and Archeology Technical Abstracts* (twice yearly) and the publications arising from its congresses enables its world-wide membership, which includes most of the world's leading conservators, to keep abreast of developments.

Rutherford's Cavendish

Edward Bullard

Madingley Rise, Madingley Road, Cambridge, UK

Sir Edward Bullard recalls his early days at the Cavendish Laboratory in Cambridge where, under the watchful eye of Lord Rutherford, he worked, and struggled, as a research student in the company of people like Blackett, Kapitza, and Cockcroft.

I FIRST saw the Cavendish nearly 50 years ago, in December 1925, when I made an unsuccessful attempt to get a scholarship. The physics practical exam was held in the large room to the right of the arch as you come in. I was

a little surprised to find that my galvanometer was permanently jammed and that the assistants and demonstrators did not think it at all odd. Indeed, it was not odd: most of the equipment in the lab was like that.

The following year I went up to Clare and embarked on the Natural Science Tripos. I found the Part I Physics lectures deeply disappointing. Alex Wood, on mechanics, roughly, covered the first book of the *Principia* and the Cavendish experiment, together with a little about gyroscopes. I found that the lack of generality and the attempts to avoid all but the simplest calculus were tedious. I went off

Mr. F. Lincoln, the head of the Cavendish workshop

Cavendish Laboratory

to listen, a little uncomprehendingly, to Pars on analytical mechanics, and also, very briefly, to Larmor. By part II the lectures had become better and they gave a sense of contact with contemporary physics.

It was, I think, early in my third year that, coming out of a lecture, I met Patrick Blackett who asked me what I was doing. I replied that I had been listening to Aston talking about mass spectroscopes. "Why?", he said, "everything he says is in his book". It came to me as a revelation, and I went to no more lectures, except to Rutherford, whom I could not resist. He would boom on, talking about all kinds of interesting things, occasionally producing gems like "integral $y \cdot dx$; dx is small, we will neglect this". He talked so easily and informally, he knew it all in an instinctive, relaxed way and the answer always somehow came out right. As someone said: "The α particles were his friends, he knew what they would do" (there was a story, which I have not verified, that in one of his early papers the mass of an α particle came out as 3.3 on which he commented: "we take four as the nearest integer").

Although the practical classes interested me I learnt almost nothing useful in them. A practical class can serve three purposes: it can teach the techniques of measurement; it can allow the student to go over the path by which the principles of physics were discovered; or it can help to give contact with contemporary physics. The practicals in the Cavendish were largely historical, tempered with some feeling that, if the equipment was available (which it wasn't), there ought to be some experiments on modern physics. As it was, we swung pendulums which had their bobs in buckets of water and tried to find the frequency of a tuning fork with a phonic motor once used by Lord Rayleigh. (The usefulness of that potentially interesting experiment was reduced by the absence of a clock that could match the stability of the tuning fork.) The trouble was, I suppose, that there was very little money for equipment and that most of the very able and distinguished men running the classes had more important and exciting things to do. Indeed, when, in my third year as an undergraduate I tried to devise some new experiments for the Part II class, I found every encouragement and immediate acceptance of innovation.

I think the physics course in the 1920s was, in an important way, preferable to that of today. It was not very difficult. A reasonably intelligent man, who was interested in the subject, who took pains to understand it, and who could write in a way that would show that he did understand it, could get a first in the tripos without wearing himself out or concentrating too exclusively on science. He could take up politics or hiking, or learn a foreign language, without feeling that he was not giving enough time to physics.

In the Cavendish one absorbed an attitude to knowledge,

and an intellectual style. A real physicist ought to be able to estimate any quantity within a factor of 10 without looking in a book, using only a pencil and the back of an envelope. The central idea was that when you really understood anything it would seem simple. When I was an undergraduate, this spirit filtered down through research students a few years older than I was, particularly through Jimmy Braddick, who was in a constant state of indignation about things that Rutherford had said to him, Paul White, a much more serious character, a mathematician and low-church Christian, and P. I. Dee, for a while my supervisor, who carried apparent omniscience with an engaging charm.

In 1929 Rutherford accepted me as a Ph D student. In those days it was usual for those starting as research students to spend the long vacation working in the 'kindergarten', an institution run by Chadwick. This was supposed to do what the undergraduate practical courses so clearly failed to do, that is, teach the techniques of modern physics. As I was going to study the scattering of slow electrons in gases I was set to learn vacuum techniques by measuring the vapour pressure of tap grease.

It proved a most instructive project and, more important, it enabled me to get to know Chadwick a little. Tap grease was a perennial problem in the Cavendish. It was normally made by a chemist in Southampton named Everett, the son of 'old Everett' who was J. J. Thompson's assistant. Old Everett had been mentioned in an agreement between J. J. and Rutherford, which specified that J. J.'s share of the lab funds would be £150 per annum "out of which he would pay his assistant". This tap grease was made by heating rubber bands with vaseline and adding paraffin wax. As Everett's product was sometimes overcooked and smelt of burnt rubber, the more fussy amongst us made our own. At about this time C. R. Burch, who worked for Metropolitan Vickers, introduced a much superior product prepared by distillation; it was, however, enormously expensive (I think £1 per pot) and in order to get it all of Oliphant's powers of persuasion were needed.

In 1929 I started work in a large room already occupied by Mark Oliphant, Phillip Moon and J. K. Roberts, all of whom were doing experiments involving vacuum techniques. After a few months I was joined by Harrie Massey. The room was just down the corridor from Rutherford's office. He would come round about once a week with Chadwick, and at odd times when he felt like blowing off steam. Once, he came in in the most cheerful good humour and said to Roberts "You know, Roberts, the time has come to consider whether your experiments are worth the liquid air they consume". On another occasion he told me that he never wanted to see me in the lab again. The next morning I got in early and managed to meet him on the stairs; he was particularly friendly. I never really got

Cavendish Laboratory

Lady Rutherford directing a gang of research students reconstructing her rock garden. The author, in shirt sleeves, looks on. Mr. Lincoln assembled these gangs on days when Rutherford was in London.

Cavendish Laboratory

to know him well but, as time went on, and particularly after I had left the Cavendish, I found that he would always listen and help me if I needed anything. I remember asking him for help in getting funds to enable one of Townsend's students to leave Oxford and come to work with me. Rutherford's reply was: "Well, I am never averse to any scheme for doing down Prof. Townsend". There was a half humorous resentment between them, dating, I suppose, from the days when they worked together in J. J. Thomson's Cavendish. On another occasion, when Townsend had made a rather intemperate attack on Massey and myself in the Royal Society's Proceedings, Rutherford met me in the corridor and, in great glee, said: "Have you seen what Townsend has said about you? What are you going to do about it". "Nothing," I replied: "Quite right," said Rutherford, "if you answer him he will wait 20 years, but he will get you in the end". It was, I suppose, a totally unjustified view of Townsend but it was enormously encouraging for me; Rutherford had a gift for that sort of thing, he could make you feel a colleague in a great enterprise. His boys were the best boys, surrounded by foolish and wicked men who did not understand what physics was really about. I think he felt himself to be an honest New Zealand farmer's boy fallen into a corrupt society; sometimes that made him rather rude to his more pompous colleagues and rather terrifying to his students. I recently asked Kapitza if he was scared of Rutherford. "Yes", he said; "terrified".

My period in the Cavendish was just before the *annus mirabilis* in which artificial disintegration and the neutron were discovered. Much has been written of this, and it was indeed the source of modern nuclear physics and engineering. My most dramatic memory is of going to the Kapitza Club (a weekly meeting of physicists, usually in Cockcroft's rooms in St Johns) and hearing Chadwick describe the Curie-Joliot results on 'penetrating γ rays', and then going the next week and hearing Chadwick again, explaining that they were really new particles—neutrons—if he had suspected the truth on the first occasion, he gave no clue).

The fame of these discoveries has obscured the feelings that preceded them. Many young men coming into the subject in the late 1920s felt that it was no time to start to work on radioactivity. The existing techniques had been pushed near their limits and many, including myself, did not realise what could be done with the emerging tech-

nology of electronics. It was Wynn-Williams and Cockcroft who, in different ways, broke the barrier. This involved not only inventing things, but also overturning deep seated traditions of do-it-yourself and not spending money. Cockcroft's elegant solution to the problem of producing 300kV of d.c. power was preceded by some very odd schemes which included using an induction coil given to the University by a collector of scientific equipment, and a Tesla coil (which was noisy enough to produce a complaint from the Master of Corpus, on which Rutherford is said to have commented: "If they don't like the noise why did they build the college there"). An early breakthrough in spending money was the purchase of the doughnut magnet, designed by Cockcroft, which was used to focus α particles. Rutherford, when showing it to a visitor, said: "That cost as much as a research student for a year—but it does twice as much work".

The feeling for economy went all through the organisation; I remember the store man trying to maintain that the existing stock of valves, World War I bright-emitter triodes, must be used up before modern types could be bought. The day-to-day detail was looked after by Mr Lincoln, the fierce head mechanic, whose bark was much worse than his bite. In my third year as an undergraduate I complained about the absence of bandages in the first-aid box, and he said: "What's the use of my keeping bandages, people only come and use them". On another occasion I asked for six inches of one inch steel tube and was surprised when he said: "Certainly I have got just the thing". He went into the room behind the workshop and produced a bicycle left, I suppose by some undergraduate, and told me to saw six inches off the cross bar.

It is easy to tell funny or slightly discreditable stories about the Cavendish in those days, but the fact remains that it was uniquely successful both in discovery and in training many of the most able and effective men of their generation—Blackett, Cockcroft, Kapitza, Oliphant and many others. The defects of parsimony and, to some extent of arrogance, were easily cured in the years that followed. In many ways the experience of the war ideally complemented and compensated for the defects of the training in the Cavendish 10 years before.

For me, Rutherford and Blackett represent most of what is best in physics, and I am deeply conscious of the exceptional advantages that I had from being a student in the right place at just the right time.

(Continued from p. 742)

Fig. 3 Changes in membrane-bound cyclase activities. BALB/c 3T3 cells were grown to confluency in 10% serum as in Fig. 1a. After washing and detaching them as in Table 1, and washing further in 0.01 M potassium phosphate (pH 7.4), 0.15 M NaCl, the cells were resuspended in Buffer A (Table 1) and lysed under nitrogen cavitation at 6000 pound inch⁻² in an Artisan Pressure Homogeniser (diameter of orifice 0.068), 5 min being allowed for equilibration. The homogenate was made 0.001 M in EDTA_{Na}, and centrifuged at 2,000 g for 5 min. Plasma membrane fractions were isolated (method to be published). Approximately 2.3 mg of protein was recovered with specific activity for 5'-AMPase of 108 nmol hydrolysed per h per mg protein at 37° C compared with 3 nmol per h per mg in the unfractionated lysate. Reaction mixtures (100 µl) contained for a, guanylyl cyclase (—●—, —▲—): 0.04 M HEPES (pH 7.6), 0.006 M MnCl₂, 0.002 M GTP, 0.0005 M EDTA_{Na}, 0.0005 M DTT, 0.3 M sucrose, 0.01 M theophylline, 0.02 M caffeine, 12 µg of plasma membrane protein, 20 µg BSA or for b, adenyl cyclase (—○—, —△—) 0.006 M MgCl₂ replaced MnCl₂ and 0.002 M ATP, 0.015 M creatine phosphate, 4 µg of creatine phosphokinase replaced GTP. Reactions were incubated for 10 min at 37° C and terminated as described in Table 1. Cyclic nucleotides synthesised were estimated with the radioimmuno assay (Fig. 1). Either varying concentrations of FGF (—●—, —○—) or insulin (—▲—, —△—) were added to incubation mixtures and results are expressed as pmol of cyclic nucleotides synthesised per min per mg of plasma membrane protein, after deduction of the value for a 10 min incubation with no hormone addition for the guanylyl cyclase mixtures (10.5 pmol) or after deduction of the zero time point for the adenyl cyclase mixtures (2.9 pmol). For both reactions synthesis was proportional to time of incubation up to 20 min. Control reactions with added cyclic nucleotides showed no appreciable hydrolysis (less than 2 pmol min⁻¹ mg⁻¹). Boiling FGF for 5 or insulin for 1 h in neutral buffers destroyed their capacity to increase cyclic GMP levels and DNA synthesis in cultured cells and their effects on cyclase enzymes *in vitro*. Addition of 1 µg ml⁻¹ BSA or purified gelatin had no effect on cyclase enzymes *in vitro*.

concentrations of FGF in the presence of hydrocortisone^{9,10} or high, non-physiological concentrations of cyclic GMP⁵ can initiate DNA synthesis in mouse fibroblasts in the absence of

exogenously-added serum. All these observations strongly implicate cyclic GMP as a positive signal which starts the chain of events leading to the initiation of DNA synthesis and cell division. The apparent transience of the increase in intracellular cyclic GMP does not necessarily negate this, since similar variations are observed in intracellular cyclic AMP concentrations after exposure of cells to adrenergic or peptide hormones whose actions are mediated by cyclic AMP²².

The observed increases in intracellular cyclic GMP concentration and DNA synthesis upon addition of high, non-physiological concentrations of insulin is probably an indirect consequence of additional decreases in intracellular cyclic AMP. Hydrocortisone, as it does not immediately change intracellular cyclic nucleotide levels or activities of the membrane-bound cyclase systems almost certainly exerts its permissive effect through the internal cellular machinery¹³.

The concept of a dualistic theory of cellular control involving cyclic AMP and cyclic GMP both in their antagonistic physiological effects²³ and in control of fibroblast cell growth⁵ may thus be extended to the receptor systems for adenyl and guanylyl cyclase of the plasma membrane and their respective hormones. These systems may possibly initiate cell growth through cyclic GMP or expression of specialised and differentiated functions through cyclic AMP. Though such a general model holds promise not only for physiological events but even more for developmental processes, there are important differences from this relationship. Analysis of cyclic AMP and cyclic GMP concentrations throughout the cell cycle in synchronised fibroblasts show that the specific, transient increase in cyclic GMP occurs early in the G1 phase, whereas cyclic AMP exhibits rhythmic changes during the cell cycle⁵. Results with insulin also stress the possible importance of a negative interference between the two cyclic nucleotide systems. It would not be surprising if growth induction in different organs or tissues in the intact animal were to be primarily controlled by a new class of polypeptide hormones, from the pituitary and submaxillary glands⁹⁻¹¹, which bind to the cell surface and activate the guanylyl cyclase system, the specificity of the inductive process being determined by differences between surface receptors on the various target cells. This could then liberate the adenyl cyclase system for use by those hormones or factors concerned with the synthesis and release of specialised products.

We thank Dr R. Dulbecco for encouragement and support, Drs R. Dulbecco and M. Shodell for criticisms of the manuscript, Miss Margaret Seeley for technical assistance and Drs M. and R. Hamilton for gifts of plasma membrane preparations. This work was supported by a fellowship from the Helen Hay Whitney Foundation to P. S. R. and grants from the National Institutes of Health to D. G. and Dr R. Dulbecco.

Evidence for a unique kind of α -type globin chain in early mammalian embryos

MAMMALIAN embryonic haemoglobins are synthesised in nucleated erythroid cells derived from the yolk sac¹. They are structurally different from foetal and adult haemoglobins. It has been generally assumed that the difference of embryonic to foetal or adult haemoglobin is solely due to an embryonic globin chain structurally related to the β chain. It was believed that embryos either synthesise no α -type chain at all or an α chain structurally identical to the adult α chain^{2,3}.

In mice and in rabbits we show the existence of a unique embryonic globin chain (x chain). The different x chains of the two species are closely related in respect to their primary structure and are very similar to the ζ chain of the human haemoglobin Portland I^{4,5}. The ζ chain can therefore be considered to be a human x-type chain. It was suggested that a haemoglobin found in early human embryos is identical with Portland I (refs 6–8).

The presented structural data and the functional relationship of x and α chains prove that the x chains are in fact α -type chains. Furthermore, we find more structural similarities between the x chains of different species than between the x and α chains of the same species. This indicates an early evolutionary divergence of x- and α -chain genes and demonstrates another case of gene duplication of globin genes during evolution⁹.

The embryonic haemoglobins of BALB/c mice and of New Zealand white rabbits were isolated. Embryonic haemoglobins can be separated from adult haemoglobins by column chromatography or acrylamide gel electrophoresis. Using CMC-urea columns, three embryonic haemoglobins are observed in mice: HbE_I, HbE_{II}, HbE_{III}. The tetramer of HbE_I consists of a pair of non- α and a pair of non- β chains: $\alpha_2\gamma_2$; HbE_{II} and HbE_{III} consist of a pair of α and a pair of non- β chains $\alpha_2\gamma_2$ and $\alpha_2\zeta_2$ respectively^{10,11}. γ and ζ chains are similar to the β chain and can be regarded as ϵ chains (refs 11–13 and our own observa-

tions, to be published). Using a pH gradient and CMC columns, we found that embryonic haemoglobins of the rabbit consist of at least six haemoglobin fractions: a group of three early eluting embryonic haemoglobins HbE_I–HbE_{III} with the chain composition $\alpha_2\epsilon_2$ plus a group of late eluting embryonic haemoglobins HbL_I–HbL_{III} with the chain composition $\alpha_2\epsilon_2$. There are at least two structurally different ϵ -chains (ref 11 and our results).

Mice and rabbit x chains were separated by chromatography^{14–16}. In mice the y chain frequently eluted close to the x chain; in rabbits separation between x and ϵ chains is usually incomplete. The x chains were digested by trypsin and the tryptic peptides were separated by the fingerprinting method. The amino acid composition of the tryptic peptides is shown in Table 1. They were compared with α and β chain sequences of mouse, rabbit and carp. According to the principle of least dissimilarity, the best correspondence was obtained using the α chains as a reference. Two peptides of the x chains are identical with typical α -chain peptides (residues 93–99 and 140–141). Several other peptides of the two x chains are similar to α -chain sequences (Table 1, Fig. 1). None of the peptides shows an amino acid composition with closer correspondence to β than to α chain peptides.

Comparing the difference of x and α chains of the same species we found that in the mouse x chain 29 amino acid substitutions are necessary in order to match a sequence of 87 amino acid residues of the α chain. The minimum difference of this stretch is 33%. The difference, if the complete chains are compared, is probably higher, since several x chain peptides are so different from α -chain peptides that they could not be matched at all (Table 1).

In the rabbit x chain we found 24 amino acid substitutions in comparison to a corresponding sequence stretch of 67 amino acid residues of the rabbit α -chain which would reflect a structural difference of 36%. The difference of the human x to the human α chain is in the same order of magnitude with 11 substitutions of a corresponding α chain sequence 38 amino acids long.

Human, mouse and rabbit x chains show much more sequence homology than the x and α chains of the same species. The difference between corresponding peptides with 49 amino acid residues of mouse and rabbit x chains is nine amino acid substitutions, whereas the difference between mouse x and mouse α chain is 19 substitutions. The difference between mouse and human x chains of a sequence of 39 amino acid residues is six substitutions, whereas the difference between mouse x- and mouse α -chain is 13 substitutions. Finally, the difference between rabbit x- and human x-chains is six sub-

Fig. 1 The amino acid compositions of the tryptic peptides of the human ζ chain and of mouse and rabbit x chains (Tables 1 and 2) were sufficiently similar to some α -chain peptides. The composition data of the human ζ chain were taken from Capp et al.⁵. The sequence homologies are shown.

Fig. 2 Scheme of the switches of human haemoglobin chains during ontogenesis. The type of haemoglobin which is synthesised is not organ specific with the possible exception of embryonic haemoglobins. For the time course of erythropoiesis in yolk sac, liver, spleen and bone marrow we used the data cited by Metcalf and Moore¹.

stitutions of a stretch of 39 amino acid residues, the difference between rabbit x and rabbit α chain is 13 amino acids. It is only possible to place a rabbit x-chain peptide into position 71-82 if the insertion of one amino acid in position 63a is accepted. This additional amino acid is also present in the α chain of the carp (Fig. 1).

We also tried to obtain data on the time of synthesis of the embryonic globin chains in the course of embryogenesis. Mouse yolk sac erythropoiesis starts at day 7 of gestation and is succeeded by liver erythropoiesis at day 12-14 (ref 10). It was previously shown that the relative rates of synthesis of the three

embryonic haemoglobins change during the course of embryogenesis. Synthesis of HbE_I decreases markedly whereas the synthesis of HbE_{II} increases during embryonic development. The synthesis of HbE_{III} seems to decrease as well¹⁷.

The rate of synthesis of embryonic globin chains was determined by labelling embryonic mouse yolk sac cells at day 9.5 of gestation with ³H-leucine at 37° C for 6 h in leucine-free tissue culture medium, and at day 11.0 with ¹⁴C algae hydrolysate in amino acid free medium¹⁵. Our data show that during the time from day 9.5 to day 11.0 of gestation the rate of synthesis of the ε-type globin chains (y and z) stays constant;

†b: nearest whole number of residues.

‡ Phenylalanine is present.

§ Half cystine is usually destroyed during hydrolysis.

|| Proline is present.

The embryonic globin chains of mouse and rabbit were separated as described (11,16). The x chains were digested with trypsin and after separation of the tryptic peptides by fingerprinting the amino acid composition analysis was carried out as described (15). Line 1 indicates the residue numbers that were homologised to known α-chain sequences. The composition data of peptides that could not be homologised to α-chain peptides are also given in the last columns of the Table.

on the other hand the synthesis of the χ chain decreases from 18% to 9% while there is an increase of α -chain synthesis from 82% to 91%. The decrease of χ -chain synthesis is thus compensated by an increase of α -chain synthesis.

Similar data have been obtained for the embryonic haemoglobins of the rabbit. Those haemoglobins which contain χ and ϵ chains (HbE_I-HbE_{III}) show a decrease of the rate of synthesis, whereas those containing α and ϵ chains (HbL_I-HbL_{III}) increase correspondingly during yolk sac differentiation¹¹. These data show that χ - and α -chain synthesis in both species is inversely correlated.

This and the above cited structural evidence proves that the χ chain takes the place of the α chain during early embryogenesis. The χ chain therefore could be expected to compensate for the α chain in situations where no α -chain synthesis is possible. Haemoglobin Portland I tetramer containing $\chi_2\gamma_2$ is observed in infants with homozygous α -thalassaemia^{7,8}.

These data taken together with suggestive evidence of others on the human χ chain⁶⁻⁸ lead us to propose the following scheme of development of globin chain synthesis in man (Fig. 2). As in mice and rabbits we expect, during early yolk sac erythropoiesis, predominantly haemoglobins of the constitution $\chi_2\epsilon_2$. Later, but during yolk sac erythroid differentiation, the α chain replaces the χ chain to give haemoglobins of the constitution $\alpha_2\epsilon_2$. The ϵ chain is replaced by the β chain after the switch of erythropoiesis from the yolk sac to the foetal liver.

In view of this scheme, the existence of ϵ_4 in human foetuses remains unexplained^{2,3}. No ϵ_4 -type haemoglobins have been observed by us during the embryonic phase of erythroid differentiation in mice and rabbits. It might well be that the globin χ chains of the embryonic haemoglobins $\chi_2\epsilon_2$ are degraded at a different rate thus leading to the formation of the ϵ_4 tetramer which is found in human foetuses.

A structural comparison of χ and α chains of mice, rabbits and of man⁵ shows the existence of a group of embryonic χ -type chains which have many features in common. Our data show that the χ -chain genes of all three species have evolved from a common ancestor gene which in turn is derived from an ancestral α -globin gene by gene duplication. We do not know when this duplication occurred, but the many similarities within the three investigated mammalian χ chains and the large common difference as compared to the α -chains suggest that the divergence of α and χ chains is much older than mammalian evolution.

Hormonal control of oestrogen receptor in uterus and receptivity for ovoidimplantation in the rat

THREE distinct states of the rat uterus with respect to ovoidimplantation have been described. The prereceptive stage lasting from day 1 to day 4 is followed by receptivity during day 5; finally, during a postreceptive period from day 6 onwards, transferred mature blastocysts do not implant if implantation on day 5 has been prevented¹. Analogous situations can be created in the castrated animal by treatment with a precise sequence of hormones: a minimum of 2 d of progesterone preparation is necessary to obtain, 18 h after the subsequent administration of a small dose of oestrogen the state of receptivity for ovoidimplantation which will last for approximately 12 h. Again, a period during which the fertilised egg cannot implant will follow the time of receptivity, as shown by egg transfer experiments¹.

Thus in both intact and castrated animals oestrogen seems to be effective only after progesterone treatment. The possible involvement of the specific high affinity intracellular oestrogen receptor (see papers of the groups of Jensen, Gorski, King, Erdos, Bresciani, Jungblut and this laboratory in ref. 2) in the control of tissue responsiveness for oestrogen has therefore been examined. We have studied the influence of progesterone and oestradiol on the level of oestrogen receptor in both the endometrium and myometrium of the castrated rat uterus. We have compared the results with the variations observed during early pregnancy. There is strong evidence that the presence of such receptors in the cytoplasm is necessary to mediate the action of oestrogen hormones on the target tissues².

We separated uterine endometrium from myometrium by gentle scraping with a scalpel. A Scatchard³ plot was made to show the binding of homogenised endometrium and myometrium supernatant fraction to ³H-oestradiol (as described previously⁴ (Fig. 1). A consistent difference between the apparent equilibrium dissociation constants of the receptor-hormone complexes of the endometrium $K_d = 3 \times 10^{-10} - 5 \times 10^{-10}$ M) and myometrium ($K_d = 6 \times 10^{-10} - 9 \times 10^{-10}$ M) may reflect different degree of interference of low-affinity sites on the binding equilibrium, since straight line Scatchard plots indicating a single class of high-affinity binding sites are obtained when the whole uterus homogenate is used as the source of the supernatant receptor^{2,4}.

The variations in the receptor concentration during pregnancy up to day 8 are shown in Fig. 2. Whether related to total soluble protein or to DNA content of the tissue, the endometrium receptor concentration first decreased

Fig. 1 Determination of the receptor concentration in the endometrium (Δ — Δ) and pooled or individual myometrium (\circ — \circ) homogenates. The uterus was removed from a 2 day pregnant rat; the endometrium and myometrium were homogenised separately in respectively 1 ml or 2 ml of the sucrose (0.25 M)— MgCl_2 (3 mM) medium. After low speed centrifugation ($800g \times 10$ min), the supernatant fractions were incubated with radioactive oestradiol for 30 min at 30°C . The receptor bound to unbound (B/U) hormone ratio and the concentration of hormone bound (B) to low-affinity receptor sites in equilibrium solutions (0.2 ml) containing 0.2, 0.5, 1.0 or 2.0 nM ^3H -oestradiol were determined by adsorption with charcoal (0.25% Norit A)—dextran (0.0025%, molecular weight 90,000) suspension (0.5 ml) for 10 min at 30°C (ref. 4.) The concentration of the oestrogen receptor binding sites is indicated by the intercept of the experimental straight lines on the abscissa; the inverse slopes of the respective straight lines are equal to the equilibrium dissociation constants ($3.5 \times 10^{-10}\text{M}$ for the endometrium, $6.25 \times 10^{-10}\text{M}$ for the myometrium preparation). Although by this technique only directly available specific binding sites are measured, it has been demonstrated¹⁰ that the concentration of endogenous oestrogen in cytosol is negligible under physiological conditions (oestrus cycle and early pregnancy) when compared to the amount of receptor. The measurement of the receptor concentration in low-speed and in high-speed ($105,000g \times 60$ min) supernatant preparations of rat uterine tissue has been shown to yield identical results¹⁰.

slightly from day 1 to day 2 to rise strongly thereafter. The receptor concentration decreased between days 5 and 8 as seen clearly when expressed on a DNA basis. The values for the myometrium receptor are considerably lower and the variations less marked.

It is known that the secretion of both oestradiol and progesterone in the pregnant rat increases from the evening of day 2 and remains substantially elevated from days 3 to 10 (refs 5,6). Therefore we performed an ovariectomy on the morning of day 2 of pregnancy. We measured the influence of oestrogen and progesterone on the level of oestrogen receptor in the uterus of rats 3 weeks after the ovariectomy. The results are shown in Fig. 2. Both hormones, alone and in combination, caused an increase in the endometrial receptor level. The increase was due partly to cell proliferation but also to a rise in the cellular concentration of the receptor. There was no additivity of oestrogen and progesterone (simultaneously administered) under these experimental conditions. Progesterone showed little effect on the myometrium, whereas oestradiol caused a large increase in the content of myometrium receptor, compared with soluble protein and total DNA. The oestradiol effect on myometrium was significantly counteracted by a simultaneous progesterone administration.

Next we examined the hormone requirements for the maintenance of the elevated endometrium receptor concentration during pregnancy. Rats were castrated on the morning of day 4, and subsequently treated either with progesterone alone or with a combination of progesterone and oestradiol. The receptor concentrations were measured on the following day and compared with these in untreated castrated rats and in intact pregnant controls. We found that neither castration nor the subsequent hormone replacement lead to marked differences in the endometrium receptor level within 24 h. This observation is in agreement with the slow turnover rate of uterine oestrogen receptor (half-life about 5 d) reported by other authors⁷.

In summary, although the presence of oestrogen receptors in the rat endometrium cells may be necessary (maximum levels coinciding with the period of oestrogen sensitivity and implantation), it does not seem to be sufficient to explain the oestrogen effects, since a high level of receptor is found also at stages of pregnancy when oestradiol fails to induce endometrium receptivity for ovoimplantation¹. Progesterone has only been clearly shown to influence the level of

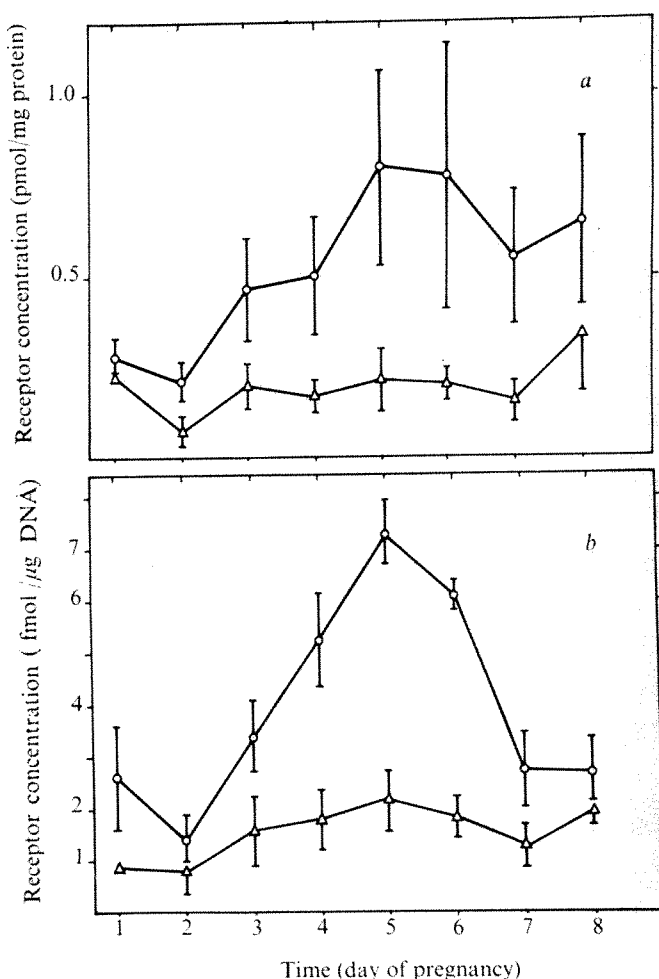

Fig. 2 Endometrium and myometrium oestrogen receptor concentrations in the rat during early pregnancy. The oestrogen receptor concentration in the low speed supernatant preparations was determined as shown in Fig. 1 in endometrium (\circ — \circ) or myometrium (Δ — Δ) from individual rates throughout the first 8 d of gestation or in a pool of four myometria (day 1). The results are shown as receptor concentration related to total soluble protein (a) or DNA content (b) of the tissues. Vertical bars show the standard deviations of the mean of at least four determinations.

Fig. 3 Effect of progesterone and oestradiol treatment on the endometrium and myometrium oestrogen receptor concentrations in castrated rats. The concentration of oestrogen binding sites in the low speed supernatant preparation was determined as shown in Fig. 1 in endometrium of individual rats (whole bars) or in pooled myometrium (shaded part of the bars, four rats per determination). The rats received subcutaneously: the vehicle (propylene glycol) alone (control, C), progesterone (P, 5 mg per injection), oestradiol (E, 0.25 μ g per injection) or both hormones (P+E). The treatment was repeated twice with an interval of 24 h and the animals were killed 24 h after the second injection. The vertical lines represent standard deviation of the mean (four determinations).

oestradiol receptors in the endometrium, the changes in the myometrium being disputable. This, together with the lack of systematic study, may account for the fact that the progesterone effect on the uterine oestrogen receptor has escaped earlier detection. Whether the progesterone effect on oestrogen receptor is realised through the stimulation of receptor synthesis or activation in all or only certain cells, or through the preferential stimulation of mitotic activity of oestrogen-responsive cells, remains to be explored.

Perhaps of even greater interest is the antagonistic effect of progesterone in the oestradiol stimulation of the oestrogen receptor level in the myometrium. The observed variations in the receptor concentration in the endometrium and myometrium between days 2 and 5 of gestation can best be interpreted by simultaneous action of the two hormones. There is therefore a possibility that by blocking the increase of oestrogen receptor level in the myometrium, progesterone inhibits the excitatory action of oestradiol⁸ and thus favours implantation. This negative aspect of progesterone action could be as important as the increase of the endometrium oestrogen receptor which it provokes. A study of changes in the progesterone receptor has recently been published⁹. This work provides another model system where the antagonistic and synergistic effects of oestradiol and progesterone may be studied at a molecular level.

Methylmercury is a potent inhibitor of membrane adenyl cyclase

THE toxicity of methylmercury has taken on added importance since it was discovered that inorganic mercury can be converted to methylmercury by bacteria in bottom sediments of lakes and homogenates of rotting fish^{1,2}. The mechanism for methylation of inorganic mercury by bacteria has been described in some detail^{3,4}. Although there have been several documented incidents involving the toxicity of alkylmercury derivatives⁵⁻⁷, the basis for methylmercury toxicity has not been defined unambiguously. One possible target site for methylmercury—the plasma membrane—is described in this communication.

Many macromolecules in mammalian cells could be modified chemically by methylmercury. In principle, any enzyme with an essential sulphhydryl group is a potential target for methylmercury. However, components of the plasma membrane must be given primary consideration since methylmercury is lipid-soluble⁸ and the plasma membrane is the cellular organelle most vulnerable to external agents. An examination of central nerve tissue from victims of the Minamata disaster in Japan revealed considerable morphological damage to plasma membranes⁹ and methylmercury has been reported to catalyse the hydration and hydrolysis of plasmalogens, when the reaction was examined in methylene chloride¹⁰. Alternatively, it is important to determine whether or not functional proteins in plasma membranes are sensitive to methylmercury. Crucial membrane activities known to be inhibited by sulphhydryl reagents include adenosine triphosphatases, acetylcholine esterase, adenyl cyclase, transport systems, depolarisation phenomena in nerve and muscle tissue and hormone binding¹¹. We have now found that methylmercury is a potent inhibitor of adenyl cyclase in rat liver plasma membranes.

Table 1 Inhibition of membrane adenyl cyclase by sulphhydryl reagents

Sulphydryl reagents	*Concentration for 50% inhibition (M)
Iodoacetic acid	3×10^{-3}
Iodoacetamide	3×10^{-3}
N-ethylmaleimide	$\sim 1 \times 10^{-3\dagger}$
p-CMB	$5 \times 10^{-3\dagger}$
p-Chloromercuriphenyl sulphonate	$4 \times 10^{-6\dagger}$
5-Bromo-5-phenyl-barbiturate	6×10^{-6}
Mercuric chloride	$\sim 1 \times 10^{-6}$
Methylmercury chloride	1×10^{-7}

* Rat liver membranes incubated for 15 min at 30°C with the sulphhydryl reagent.

† Rat liver membranes incubated at 22°C for 15 min¹⁵.

‡ Heart muscle adenyl cyclase at 37°C (ref. 16).

Methylmercury chloride was synthesised by the method of Imura *et al.*¹². Purity was verified by thin-layer silica gel chromatography developed with diethyl ether: petroleum ether (3:7). The concentration of aqueous solutions of methylmercury chloride was quantitated using a Coleman mercury analyser. Rat liver plasma membranes were prepared by the Neville procedure as modified by Rodbell¹³ and adenylyl cyclase was assayed by the Krishna technique¹⁴. The final assay media contained 25 mM Tris, pH 7.6, 1 mM EDTA, 5 mM MgCl₂, 5 mM theophylline, 15 mM NaF, 1 mM ³H-ATP (2.5 μ Ci), 2 mM cyclic AMP, 20 mM creatine phosphate, 1 mg ml⁻¹ creatine kinase and 0.1% bovine serum albumin. Membranes were treated with methylmercury chloride by incubating a sample (80 μ g protein) with 200 μ l of 0.01 M phosphate buffer, pH 7.00, containing various amounts of methylmercury chloride. After 15 min of incubation, 5 ml of phosphate buffer was added and membranes were centrifuged at 20,000g for 10 min at 4° C. The pellet was dispersed carefully in buffer using a 20 gauge hypodermic needle and assayed in quadruplet for NaF stimulated adenylyl cyclase activity. Enzyme activity is expressed relative to the control which consisted of membranes treated as described above with buffer containing no methylmercury chloride. The control membranes catalysed the formation of 1.00 nmol cyclic AMP per mg protein per 10 min in the presence of NaF.

Adenylyl cyclase activity in rat liver plasma membranes proved to be extremely sensitive to methylmercury chloride (Fig. 1). Concentrations of methylmercury chloride as low as 10⁻⁸ to 10⁻⁹ M partially inhibited enzyme activity. Fifty per cent inhibition occurred at 1 \times 10⁻⁷ M when incubation was carried out at 30° C for 15 min. This inhibition was not due to inhibition of the ATP regenerating system in the assay since the membranes treated with methylmercury were washed thoroughly before assaying for adenylyl

cyclase activity, and creatine kinase would have been in excess of methylmercury even without washing. It is interesting that when membranes were incubated with methylmercury at 4° C adenylyl cyclase was not inhibited. It is possible that inhibition of membrane adenylyl cyclase activity requires diffusion of the inhibitor through the membrane phase, which could be reduced drastically below the thermal transition point of the lipids. Inhibition by methylmercury at 30° C was reversed by mercaptoethanol but only 80% of the original activity could be restored.

The effectiveness of methylmercury as an inhibitor of adenylyl cyclase is compared with several other sulphhydryl reagents in Table 1. Methylmercury is the most potent inhibitor of adenylyl cyclase reported so far. Two properties of methylmercury probably account for this: first, organomercurials generally react quite rapidly with protein sulphhydryl groups; secondly, methylmercury is quite lipid-soluble and would be expected to concentrate in the membrane phase when distributed between an aqueous phase and membranes.

The molecular basis for methylmercury toxicity is not known and there may of course be multiple effects. But, any consideration of alkylmercury toxicity must take into account the sensitivity of adenylyl cyclase to methylmercury and the pivotal role this enzyme plays in the metabolism of mammalian cells.

Effects of thyroid state on adrenoceptor properties

RECENT studies with frog hearts have shown that the adrenoceptors that mediate inotropic responses are altered qualitatively by ambient temperature¹⁻³. The characteristics of these receptors changed from β to α when the temperature of the isolated hearts was reduced through a critical range of 17°-22° C, which suggested that α and β adreno-

Table 1 Effect of altered thyroid state on the sensitivity of rat left atria to adrenergic agonists

ceptors represent allosteric conformations of the same structure³. Although a change in adrenoceptor characteristics qualitatively similar to that found in the frog heart seems to occur in the mammalian myocardium^{1,4,5}, the physiological significance of a temperature-induced change is obviously limited in homeothermic species. But, several observations indicate that conditions which promote α -adrenoceptor properties, including cold¹⁻³, iodoacetate or fluoroacetate⁶ or dinitrophenol¹, inactivity of skeletal muscle⁷ and increased vagal influence on the myocardium⁸, are associated with a decrease in metabolic activity. Therefore, it seemed possible that hypothyroidism would produce similar changes in receptor properties. We report here that the characteristics of adrenoceptors mediating inotropic responses in hypothyroid rats are similar to those in normal hearts at low temperatures.

Hypothyroidism was induced in male Sprague-Dawley rats (180–220 g) by surgical thyroidectomy. Experiments were performed on isolated left atria 6–10 weeks after the operation. By this time growth was retarded and the fur was dry. Serum thyroxin levels determined by the competitive protein binding assay⁹ were significantly lower (25 ± 4 ng ml⁻¹) than those of control animals (57 ± 6 ng ml⁻¹). Control preparations were from either sham-operated age-matched, or weight-matched animals. The results from the two control groups were almost identical and were pooled. A third group consisted of thyroidectomised rats injected daily with thyroxine (T₄, 1.0 mg kg⁻¹) or triiodothyronine (T₃, 0.25 mg kg⁻¹) for 1 week before use. The animals were anaesthetised with ether and the hearts were removed immediately. The left atria were suspended in Krebs-Henseleit solution at 31°C bubbled with 5% CO₂ in O₂, and were stimulated through platinum electrodes with square-wave pulses at a voltage slightly above threshold, a duration of 3 ms and a rate of 1 Hz. Isometric contractions were recorded by a force-displacement transducer and Grass polygraph. Cumulative concentration-response curves for various agonists were determined before and after a 40 min incubation with propranolol (0.04–4.0 μ M) or ³H-phenoxybenzamine (³H-POB, specific activity 33 mCi mmol⁻¹, 7.3 μ M). Responses are expressed as percentage of the maximal control response. Atria exposed to ³H-POB were washed for 2 h and then dismantled and freeze dried. The dry tissue was weighed and dissolved in NCS tissue solubiliser; radioactivity was measured in a liquid scintillation counter. The retained radioactivity is expressed as d.p.m. per mg dry weight.

Thyroidectomy did not significantly alter either the basal contractile force of left atria or the maximal increase in force produced by the sympathomimetics tested. But, selective changes in sensitivity to the various amines were re-

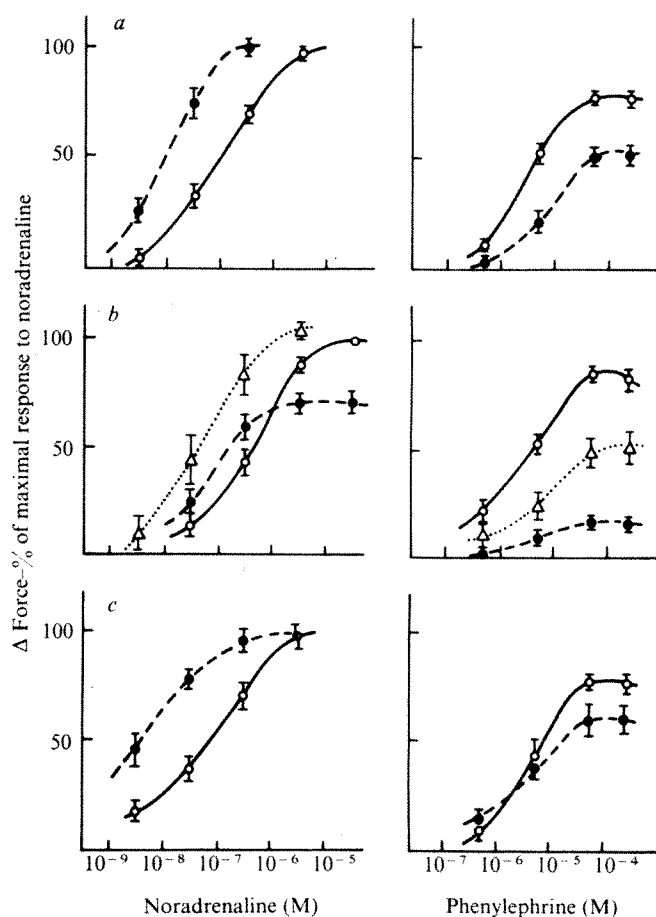

Fig. 1 Effects of phenoxybenzamine on inotropic responses of rat left atria to noradrenaline and phenylephrine. Rats were normal (a), thyroidectomised (b); and thyroidectomised +T₃ or T₄ (c). 4.0	3.01 ± 0.37 (5)	<0.005	1.39 ± 0.07 (8)	<0.005	2.54 ± 0.38 (5)

* Mean + s.e. of log dose-ratio (logarithm of the ratio of NA ED₅₀s after and before propranolol). Numbers of experiments are given in parentheses. *P* values indicate significance of differences between adjacent groups.

flected in significant changes in the concentrations producing half-maximal responses. Table 1 shows that the sensitivity of atria to isoproterenol and noradrenaline, agonists with predominantly β -adrenoceptor activity in the heart, was significantly lower, whereas sensitivity to the α -adrenoceptor agonist phenylephrine was significantly higher in the thyroidectomised than in the control rats. Sensitivities to all three agonists were returned to or beyond the control values in the thyroidectomised animals treated with thyroid hormone. There were also reciprocal changes in the effectiveness of α and β -adrenoceptor antagonists. The inhibitory potency of propranolol was at least ten times less in the thyroidectomised than in either the control or the thyroidectomised, hormone-treated groups (Table 2). Conversely, POB inhibited inotropic responses more effectively in hypothyroid than in the other groups (Fig. 1). In control atria POB potentiated inotropic responses to noradrenaline and moderately inhibited those to phenylephrine. In preparations from thyroidectomised rats a similar exposure to POB partially inhibited responses to noradrenaline and blocked those to phenylephrine significantly more than in the controls. Maximal responses of these preparations to CaCl_2 were unaltered by POB. Thyroid hormone treatment reduced the effectiveness of POB on responses to both noradrenaline and phenylephrine to about the control level. In association with the increased blockade, significantly more ^3H -POB was bound to the hypothyroid myocardium ($25,122 \pm 1,365$ d.p.m. ml^{-1} dry weight) than to preparations from either control ($19,310 \pm 1,176$) or thyroidectomised, hormone-treated rats ($16,384 \pm 857$). When atria from thyroidectomised rats were exposed to ^3H -POB in the presence of $26.5 \mu\text{M}$ phentolamine, protection of α adrenoceptors was shown by a significant reduction in both the blocking effectiveness (Fig. 1, dotted lines) and the binding of ^3H -POB ($18,212 \pm 1,190$). These data indicate the presence in hearts from hypothyroid rats of α adrenoceptors that are absent or are unreactive with POB in euthyroid animals. They also suggest that, as in frog hearts at low temperatures³, α adrenoceptors represent a considerably higher percentage of the total binding sites for POB in hypothyroid myocardium than in normal vascular smooth muscle¹⁰.

The observed shift in the balance of α and β adrenoceptors involved in inotropic responses can be interpreted either as due to reciprocal changes in the sensitivity or availability of two independent pools of receptors, or to a single type of adrenoceptor that is qualitatively altered by changes in thyroid state. The experiments reported here do not distinguish between these possibilities. But, analogies between this model and temperature-induced receptor transformation, where the second interpretation was supported by the observation that β adrenoceptors did not appear at high temperatures after α adrenoceptors had been alkylated irreversibly at a low temperature³, suggest that the changes in responsiveness produced by altered thyroid hormone levels reflect an interconversion of myocardial α and β adrenoceptors. In view of the reported sensitivity of allosteric systems to thyroid hormones^{11,12}, this interconversion can be envisaged as an allosteric change in a single basic type of adrenoceptor, as proposed earlier³.

Such a change in adrenoceptor characteristics due to altered thyroid hormone levels could explain several published observations, including a decreased blocking potency of propranolol in the hearts of hypothyroid rats¹³, a selective increase in adrenergic stimulation of the aorta of hypothyroid rabbits¹⁴, a diminished lipolytic response to noradrenaline in adipose tissue from hypothyroid human subjects¹⁵, a decreased adrenergic vasoconstriction, reversed by pronethalol, in the hind limbs of hyperthyroid dogs¹⁶, and an increased sensitivity to phenylephrine and decreased sensitivity to isoproterenol of atria from propylthiouracil-pretreated rats^{17,18}.

Although both α and β adrenoceptors can mediate posi-

tive inotropic responses in the mammalian myocardium¹⁹, the underlying mechanisms may differ. It has been reported that stimulation of α adrenoceptors is not associated with an 'oxygen-wasting' effect²⁰, and is not accompanied by increased accumulation of cyclic AMP²¹. It is therefore tempting to speculate that changes in adrenoceptor characteristics play a role in the adaptation of mechanical responses of the myocardium to its metabolic state.

Stereopsis in dynamic visual noise

A NOISE signal has the useful property that convolution of the output spectrum with the reciprocal of the input spectrum gives a measure of the characteristics of the transmitting system. In visual perception it is not possible to obtain the output spectrum directly, but an observer can report on features of the 'perceptual output' of the visual system¹. One striking characteristic which may be observed is the generation of stereoscopic depth merely by an interocular delay in transmitting binocular dynamic visual noise.

Ross² has recently described the effects of an interocular delay in perception of random dynamic noise (an electronic snowstorm) generated by a sophisticated computer technique. He interpreted his results as showing that a temporal rather than disparity between the two eyes may act as a signal for stereoscopic depth. The concept of stereopsis from temporal disparity is a radical one and needs to be critically examined before being fully accepted. I shall describe some observations and a theoretical viewpoint which seems to provide an explanation for dynamic noise stereopsis within the framework of stereopsis from spatial disparity.

The display used for the observations consisted of

random visual noise generated by a detuned television receiver. An interocular delay of up to 100 ms may be produced by the classic technique of a neutral density filter in front of one eye³. Observation of the dynamic noise with a one log unit filter (creating a delay of about 30 ms at 10 trolands when fully adapted³) gave rise to a number of perceptual experiences which have been spontaneously confirmed by six observers. The noise exhibits a considerable depth, perhaps 10% of the viewing distance, and also a streaming motion which is leftwards in front of the point of fixation and rightwards behind fixation with the filter over the left eye. Direction of movement reverses with the filter over the right eye. The motion had the characteristics of motion in a landscape viewed from a moving train, such that points near fixation rotated slowly whereas points well in front of or behind fixation moved more quickly. Movement is leftwards in front of fixation with the filter over the left eye. Direction of movement reverses if the filter is switched to the right eye.

The range of interocular delays for depth probably depends on the density and spatial distribution of the dynamic noise. In my display depth could be perceived with as little as 5 ms delay and as much as 70 ms, the maximum obtainable. One interesting observation was that depth and in particular movement were enhanced by tracking the movement of one depth plane across the screen. Tracking also seems to enhance the unity and salience of the plane which is being tracked. In contrast tracking the conventional Pulfrich pendulum against a plain background has the effect of abolishing depth.

As a control for any peculiarities of the television noise which may have influenced the results, observers tilted their heads from vertical to horizontal. The scan rate in the transverse plane through the two eyes changes from 64 μ s to 40 ms between vertical and horizontal. The plane of movement rotates to remain parallel to the two eyes,

Fig. 1 A, Sequence of possible events at three points in time. Left and right eyes are depicted as viewing events only at t_2 . A spot at point a is transmitted by the right eye (●) at time t_1 . As a result of the interocular delay the same spot is transmitted to the left eye at time t_2 (○). If a second spot happens to appear at a' to the right of a such as to be transmitted at time t_2 , a spatial disparity is produced and a spot will be perceived in a different depth plane at b . The monocular sequences of a spot at $a(t_1)$ followed by a spot at $a(t_2)$, and a spot at $a'(t_2)$ followed by one at $a'(t_3)$ are both preconditions for monocular apparent movement to the right, which may therefore be associated with the spot at depth b . B, reversal of both depth and movement when the second spot appears to the left of a at a'' rather than the right. In a random display both sequences A and B will occur, producing both rightward movement behind the point of fixation and leftward movement in front. The distances from a to a' and a to a'' will vary with a Poisson distribution depending on the density of the visual noise.

and otherwise no change in the percepts described was reported.

These observations confirm that stereopsis may be obtained by interocular delay in viewing random noise. In this situation there is no correlation between the signals from the two eyes at any instant in time. It is therefore difficult to understand what can give rise to a perception of a range of disparities in the stimulus. The model I propose is based on the assumption that the two percepts of depth and movement arise from the same operation on the dynamic noise stimulus. Thus Ross's hypothesis of depth produced by temporal disparity also implies that movement can be produced by temporal differences alone, whereas logically movement involves both temporal and spatial displacement. To resolve this difficulty, I considered the microstructure of the dynamic noise, rather than regarding it as random and therefore unpatterned. Figure 1 shows how depth and movement both arise from chance associations of points at different times in the random display. The single postulate of an association between depth and movement arising from the same pair of points is all that is required to produce the percept of a rightward-moving spot behind the plane of fixation. Such an association between the monocular movement and binocular depth is not unlikely since stationary monocular stimuli tend to be drawn to a stereoscopically defined depth⁴.

It is difficult to reconcile Ross's description of a single depth plane with the dense range of depths reported by my observers.

Preliminary observations of my dynamic noise stimulus with a dark central square confirm that depth is now perceived predominantly to the rear of the plane of the card. This may be due both to gestalt figural organisation favouring an underlying as against overlying interrupted surface, and to the difficulty of making tracking eye movements with the square present.

My observations support the hypothesis that an interocular delay produces a random distribution of spatial disparities in a dynamic noise stimulus. Each disparity is associated with a certain rate of apparent movement, giving rise to the perception of moving depth planes. The observations may thus be accommodated within the conventional framework of stereoscopic theory.

I thank Stuart Anstis for discussions. This work was supported by an SRC grant.

Contractility in *Spirostomum* provides for nonelectrogenic calcium regulation through energy-dissipative metabolic processes in the absence of membrane excitability

ATTEMPTS to carry out *in vivo* pharmacological analyses of the events leading to contraction in fast acting muscle systems have been hampered by problems due to, for example, intracellular diffusion, cell-cell interactions and extracellular control mechanisms, which arise in part because of the multicellular organisation of many vertebrate muscle systems. Their effect is to impede accurate measurement of rapid changes in the physiological and ultrastructural states throughout the system in response to

specific stimuli. The most troublesome aspects of these problems can be bypassed through the use of single-celled models which have the same properties of excitability as do muscle systems.

An essential feature of contraction in the ciliated protozoan *Spirostomum*, as in muscle, is the requirement for calcium to couple stimulation and contraction. There is a temporal relationship between calcium release into the cytoplasm and the onset of contraction in cells micro-injected with the calcium-sensitive, bioluminescent protein aequorin¹. In spite of the similarity in calcium dependency, systems such as *Spirostomum* and muscle differ in the ultra-structural organisation and energy requirements of their contractile apparatus²⁻⁴. In addition, *Spirostomum* responds to many chemical and physical stimuli in the absence of recordable changes in the electrical properties of the cell membrane¹. The response is a very specific set of contractions and provides a means of examining the biochemical pathways which may regulate calcium release during pharmacomechanical stimulation.

Dikstein⁵ suggested that several redox systems in cells are in such tight equilibrium with redox substrates and

Fig. 1 Time of course and magnitude of the contractile responses of *Spirostomum* to treatment with 10^{-4} M (O) and 10^{-5} (Δ) PMS.

products as to affect ATPase activity, energy coupling and excitation. Such regulation of metabolic activity can be studied by varying the redox ratio NADPH: NADP⁺ (and NADH: NAD⁺ ratio through transhydrogenation). Some NADPH is generated during the biosynthesis of pentose monophosphates, and it functions as a reducing equivalent in the biosynthesis of fatty acids, steroids and certain purines. Some of the reducing equivalents from NADP are oxidised through the microsomal respiratory chain mediated by cytochrome P-450 and atmospheric oxygen as part of the hydration of toxic substances⁶. The availability of NADPH can be controlled by an intermediate hydrogen carrier, phenazine methosulphate (PMS),

Fig. 2 Influence of PMS on cells depolarised in high KCl medium. The most significant effect occurs at 40 mM KCl when there is a 33% decrease in the maximum number of contractures exhibited by the cell under conditions of maximal stimulation. Concentrations of KCl: O, 10 mM; Δ, 20 mM; ■, 40 mM.

which accepts hydrogen from NADPH (and NADH) and transmits it to a suitable oxidising agent such as neotetrazolium or oxygen. This generates an energy sink and deprives mitochondria of reduced substrates.

When we treated *Spirostomum* with 10^{-4} M and 10^{-5} M PMS in a medium consisting of 2 mM NaCl; 0.5 mM KCl; 0.05 mM CaCl₂; 0.1 mM KH₂PO₄, and 0.1 mM KOH (pH 6.3) contractures were induced in each cell (Fig. 1). Data were tabulated according to the method of Sleigh⁷ who counted contractures per minute for several cells at regular intervals as a direct assay of their behavioural responses to pharmacomechanical stimuli. At the higher concentration of PMS each cell made a maximum

Fig. 3 Net effect of the calcium ionophore A-23187 at 10^{-3} M (●). Total inhibition of PMS induced contractures occurs in calcium-free Chalkey's medium (□).

of twelve contractures per minute during the first minute of stimulation, followed by a slower exponential decay at a rate of two contractures per minute until contraction stopped within 30 min. Further treatment with PMS did not elicit further contractures. To insure that PMS was not initiating contractures by depolarising the cell membrane, the concentration of KCl in the medium was adjusted at 10 mM, 20 mM and 40 mM to depolarise the membrane before treatment. Figure 2 shows that a maximum of 33% depression of 10^{-4} M PMS-stimulated contractures occurred when cells were preincubated in 40 mM KCl.

At the cessation of PMS-induced contractures, the terminal vacuole of the cell enlarged, occupying a third to a half of the cell volume. This indicated that the osmotic activity of the vacuolar space increased, possibly due to the sequestration of Ca^{2+} during relaxation after PMS-induced contractures. Vacuolar calcium concentration has been reported⁸ to increase after repeated mechanical and electrical stimulation of *Spirostomum*, suggesting that PMS action is metabolically linked to cyclical calcium movements in the cellular compartments. To test this hypothesis, the calcium ionophore A-23187 (Eli-Lilly) was added to calcium-free and complete medium in a concentration 10^{-5} M for 10 min before stimulation with PMS. Preincubation did not affect the ciliary locomotory activity. As Fig. 3 shows, in the presence of 0.05 mM Ca^{2+} the cell still made the maximum number of contractures, but these decayed at two to three times the initial rate going to baseline in 5 min. In calcium-free medium, preincubation in A-23187 followed by PMS stimulation produced a single contraction from which the organisms failed to recover. These results suggest that the cell accumulates calcium from the medium, as Jones⁹ suggested, which would then be available for activation. Pautard¹⁰ indicated that some membrane-limited calcium is bound tightly in the form of hydroxyapatite in *Spirostomum*. Our results might also indicate the slow chelation of stored calcium by the ionophore and subsequent free diffusion of the ion away from sites of calcium storage and release. The terminal vacuole failed to enlarge

during treatment with the ionophore and PMS, indicating that calcium was being removed through chelation with the ionophore, which then prevented calcium sequestration.

Figure 4 shows the effect of chlorpromazine and dicyclohexyl carbodiimide (DCCD), which Maran *et al.*¹¹ reported to inhibit PMS activation of *Vorticella*. Both substances inhibit enzymatic reactions which involve transfers of inorganic phosphate. Our results indicate that DCCD eliminated PMS induced contractures and elicited no further responses. Chlorpromazine depressed the PMS response. This drug, however, showed some delayed activity of its own, independently inducing contractures between 3 and 5 min after application.

Our results support the concept that calcium movements, and hence contractility, can be influenced directly by changes in the metabolic state of a contractile cell apparently independently of any alteration in the external concentration of ions governing the electrical properties of the membrane or of contractility. Storage of Ca^{2+} within cellular compartments against its electrochemical gradient represents a source of chemical potential energy. Presumably, the release or efflux of calcium can be coupled to the synthesis of energy-rich intermediates which may be used for resequestration and for the active processes involved in contraction¹². Ultimately in *Spirostomum*, such a system would run down because the energy available to re-establish a calcium chemical potential is continually depleted in the presence of PMS by other active processes within the cell. We suggest that motile or contractile processes such as dividing cells, amoeboid movement, cytoplasmic streaming and other processes with an implied calcium dependency, may well depend on local changes in metabolism which in turn regulate the amount of free calcium within various cytoplasmic compartments.

Inhibition of interferon action by plant lectins

IN spite of various theories, the mechanism of the antiviral action of interferon¹⁻³ remains obscure. Previous work indicated that it does not have to penetrate into target cells to exert its effect. Mouse interferon preparations, when covalently

Table 1 Effect of lectins on antiviral activity of Sepharose-bound interferon

					(8,192)	

Mouse L cells were cultivated in 35 mm plastic Petri dishes (5×10^5 cells per dish) in Eagle's minimal essential medium (MEM) and Hanks salt solution, containing 10% calf serum. After removal of medium the cells were washed once with 1 ml PBS and incubated for 1 h at 20° C in the presence of respective lectin solutions in PBS (0.5 ml). Thereafter the lectin solutions were removed and the cells washed once with 1 ml of PBS. IF-Sepharose, prepared as described previously⁴, was treated with lectin by incubating 5×10^4 beads with 0.5 ml lectin solution in PBS for 16 h at 20° C. Thereafter the beads were washed once with 4 ml PBS and suspended in 1 ml MEM without serum. Control Sepharose 4-B beads (Pharmacia Fine Chemicals) were treated identically. IF-Sepharose or control Sepharose beads were then added to the cells (one bead per ten cells) and incubated for 5 h at 37° C. After removal of the beads the cells were challenged with EMC at a multiplicity of infection of 0.1. (In the experiment with con A the cells were washed once with 1 ml of 0.5 M α -methyl mannoside PBS before infection with virus to minimise toxic effects of con A.) Viral yield was determined after 16 h of incubation at 37° C by haemagglutination of human red blood cells of type O in serial two-fold dilutions of virus suspensions⁵. The numbers represent the reciprocal of the highest dilution that showed haemagglutination. The lectin preparations were used at the following protein concentrations⁷: PHA (Phytohaemagglutinin, M form, Grand Island Biological Co.), 4.1 mg⁻¹ ml; con A (A grade, Calbiochem), 1.6 mg⁻¹ ml; lotus lectin (Fucose-Binding Protein, Miles), 0.22 mg⁻¹ ml or 0.67 mg⁻¹ ml (in parentheses). Orange lectin (prepared from Osage orange seeds according to Ahmed *et al.*⁸, using the material precipitating between 0-85% ammonium sulphate saturation after dialysis against PBS), 12 mg⁻¹ ml. The same negative results as shown for Orange lectin were obtained with partially purified lectins from *Lens culinaris* and *Ulex europaeus*. Lens lectin was prepared as described by Sage and Green⁹; crude extracts were fractionated with ammonium sulphate and the fraction precipitating between 33 and 66% saturation was dialysed against water. The resulting precipitate was dissolved in PBS to a protein concentration of 22 mg⁻¹ ml. Extracts of *Ulex europaeus* seeds were fractionated with ammonium sulphate as described by Osawa and Matsumoto¹⁰. Crude haemagglutinin 1 and 2 separating at 0-40 and 40-70% ammonium sulphate saturation were dialysed against PBS and used at protein concentrations of 4.5 and 7.5 mg⁻¹ ml, respectively. When assayed in serial twofold dilutions, all lectin solutions used agglutinated human red blood cells, type O, at maximal dilutions of 1/64-1/128, except the orange lectin solution, which gave haemagglutination at a maximal dilution at 1/512.

bound to Sepharose beads, retained full antiviral activity, even after multiple cell-to-cell transfers⁴. Physical restriction of Sepharose-bound interferon to a well defined area on the cell monolayer protected only cells in immediate contact with the insoluble interferon preparation, but not those unable to make such contacts. This excluded the possibility that soluble interferon diffused from the Sepharose beads to which it was attached⁶. If indeed interferon induces its antiviral effect by interaction with the cell surface, interferon-sensitive cells should possess specific receptor sites. We report here the inhibitory action of certain plant lectins on the action of interferon.

We used Sepharose-bound interferon (IF-Sepharose) to assay for possible inhibitory effects of plant lectins on the induction of the antiviral state. This approach facilitates

removal of unabsorbed lectin by simple washing, which is not possible with soluble interferon. Either mouse L cells, IF-Sepharose or both were preincubated with a solution of lectin in phosphate-buffered saline (PBS). In control experiments Sepharose 4-B beads were treated identically. IF-Sepharose or equal quantities of control beads were then incubated with mouse L cells for 5 h at 37° C in serum-free medium. After removal of the beads, the cells were challenged with encephalomyocarditis virus (EMC) and viral yield was determined by haemagglutination (Table 1).

Lectins derived from *Canavalia ensiformis* (concanavalin A, con A), *Phaseolus vulgaris* (phytohaemagglutinin, PHA) and *Lotus tetragonolobus* (lotus lectin) abolished the antiviral effect of IF-Sepharose, when both IF-Sepharose and the cell monolayer were preincubated. No effects were seen with lectins

Table 2 Reversal of interferon inhibitory action of lectins by lectin-specific substances

Lectin bound to IF-Sepharose	cells	Treatment with	Viral yield
—	—	None	32-64
—	PHA	None	2,048-4,096
—	PHA	D-galactose	2,048-4,096
—	PHA	Fetuin	256
Con A	—	None	2,048-4,096
Con A	—	D-galactose	4,096
Con A	—	α -Methyl-mannoside	256
—	Con A	None	2,048
—	Con A	D-galactose	2,048
—	Con A	α -Methyl-mannoside	64

L cell monolayers or IF-Sepharose beads were incubated with lectin solutions as described under Table 1. Cells were washed once with 1 ml PBS, followed by incubation with 0.5 M D-galactose, 0.5 M α -methyl mannoside, or 10 mg⁻¹ ml Fetuin (Sigma) in PBS. After 15 min at 20° C the saccharide or glycoprotein solutions were removed, cells were washed once with 1 ml PBS and incubated with fresh IF-Sepharose beads as described under Table 1. Con A-treated IF-Sepharose beads were washed with 4 ml PBS, then incubated for 15 min at 20° C with 1 ml D-galactose (0.5 M) or α -methyl mannoside (0.5 M), followed by washing with 4 ml PBS. The washed IF-Sepharose beads were then layered on to L cell monolayers and their antiviral activity was determined as described in Table 1.

derived from Osage orange seeds, *Lens culinaris* and *Ulex europeus* when used under comparable conditions. When only the cell monolayer was preincubated with lectin, PHA still inhibited interferon action completely, whereas con A and lotus lectin were less inhibitory. In contrast, preincubation of IF-Sepharose alone had little effect in the case of PHA, yet pronounced effects were seen with con A and lotus lectin. The haemagglutinating titres of the lectin solutions used, when assayed with human red cells of group O, were quite comparable. They remained unchanged when the lectin solutions were titrated after preincubation with cells or beads. Similarly, no significant decrease in protein concentration was found after preincubation with either cells or beads. Therefore the amounts of lectins that remained bound to either cells or beads seem to have been rather small, undetectable in our assay conditions. Preincubation of cells, beads or both with these lectins had no detectable effect on viral yield when determined by haemagglutination (Table 1).

As Table 2 shows, the interferon inhibitory action of PHA was almost completely reversed by fetuin, a glycoprotein with high affinity for this lectin. No reversal was observed after treatment with galactose. Likewise, treatment of con A-preincubated cells or IF-Sepharose beads with α -methylmannoside almost completely restored the antiviral effect of IF-Sepharose. Identical treatment with galactose had no effect. We were unable to reverse the interferon inhibitory action of lotus lectin using solutions of L-fucose, a sugar of high affinity for this lectin. This might indicate that interferon inhibitory action by this lectin either is unrelated to its carbohydrate-binding property, or is due to very tight binding to oligosaccharide components that cannot be replaced by this monosaccharide.

Recent data indicate that mouse interferon is a glycoprotein with strong affinity for con A (ref. 11). Likewise, rabbit interferon has been shown to contain terminal neuraminic acid residues attached to penultimate galactosyl residues¹². Inhibitory effects of lectins on the antiviral action of interferon therefore could be caused by binding to the interferon molecule or to the cell surface. Table 1 suggests that both phenomena are possible.

There was pronounced inhibition of the antiviral activity when only the cells were preincubated with PHA, whereas little inhibition resulted from preincubation of IF-Sepharose alone. In contrast, inhibition by con A was more pronounced after preincubation of IF-Sepharose than after preincubation of the cells, although in the latter case appreciable inhibition was also observed. Inhibition by lotus lectin seems to be analogous to that by con A. The reversal of the interferon inhibitory action of PHA and con A by lectin-specific glycoprotein or saccharide solutions further supports the interpretation that the phenomena observed are due to the carbohydrate-binding properties of these substances.

It has become more apparent that certain peptide hormones exert their effects by interaction with the cell surface without penetration into the cell, chiefly because of Cuatrecasas' work with Sepharose-bound insulin¹³. In the case of insulin, receptor sites on the cell surface have been shown to be carbohydrate-containing macromolecules. These receptor sites bind to specific plant lectins; binding of lectin to the cell surface before addition of insulin blocks or modifies the hormone's action¹⁴. There is a striking parallel between the action of insulin and interferon: both diffuse from the site of formation through the blood stream to distant sites; both remain active when attached to an insoluble support, and both are inhibited by pretreatment of target cells with plant lectins. Although it is conceivable that the interferon inhibitory action of PHA is due entirely to specific binding of the lectin to interferon receptor sites on the cell surface, interpretations based on non-specific steric effects or electrostatic charge effects produced by the bound lectin are possible. Whether interferon-specific receptor molecules can be isolated from the cell membrane of interferon-sensitive cells and whether these molecules indeed bind to PHA and related lectins, remains to be established.

We thank Drs C. Chany, B. Galliot and M. J. Chevalier for IF-Sepharose and Drs Grossberg and Jameson for L cells and virus; we thank them all for advice and encouragement. Actinomycin D-induced breakage of human KB cell DNA

ACTINOMYCIN D is a potent inhibitor of RNA synthesis both *in vitro* and *in vivo*^{1,2}. Its mode of action involves the intercalation with DNA at G-C regions and prevention of polymerase movement along the template^{3,4}. Actinomycin D has also been shown to inhibit DNA synthesis, cell division and colony formation in mouse L cells⁵. We have studied the effects of this drug on the DNA of human KB cells in culture. Extensive DNA breakage was induced even at quite low concentrations of the drug.

When human KB (carcinoma of the nasopharynx) cells were treated with different concentrations of actinomycin D for 2.5 h, the rate of DNA synthesis, as measured by the incorporation of ³H-thymidine was greatly reduced at a concentration as low as 0.01 $\mu\text{g ml}^{-1}$ (Fig. 1). At concentrations greater than 10 $\mu\text{g ml}^{-1}$, DNA synthesis was inhibited completely.

To determine the effects of the drug on DNA breakage, cells were prelabelled with ³H-thymidine and treated with actinomycin D for 3 h. The cells were then lysed and the DNA was analysed by alkaline sucrose gradient centrifugation⁶. Figure 2 shows that fragmentation of DNA was induced by the drug at a concentration as low as 0.01 $\mu\text{g ml}^{-1}$. Moreover, the size of the fragments decreased with increasing concentrations of the drug. Figure 3 shows that increasing the treatment time with 10 $\mu\text{g ml}^{-1}$ of actinomycin D resulted in more extensive fragmentation of the DNA.

When fragmentation of DNA occurred the treated cells were

completely attached to the surface of tissue culture flasks. Less than 1% of the cells survived, however, at concentrations higher than $0.1 \mu\text{g ml}^{-1}$ of the drug as measured by colony formation (Table 1). It is possible that fragmentation of the DNA contributes to inhibition of DNA synthesis and loss of cell viability.

The possibility of DNA repair after removal of the drug was examined next. Cells prelabelled with ^3H -thymidine were treated with actinomycin D for 3 h, washed extensively with phosphate buffer saline, and incubated at 37°C for 10 h in growth medium in the absence of the drug. The DNA was then analysed by alkaline sucrose gradient centrifugation (Fig. 4). A comparison

Fig. 1 Human KB cells grown on monolayers were trypsinised and 10^6 of them in 5 ml of alpha minimal essential medium (flow laboratories) + 10% foetal calf serum were seeded in 25 cm^2 Falcon tissue culture flasks and allowed to attach for 1 h at 37°C . Actinomycin D (Merck, Sharpe and Dohme) was then added. After 2 h, ^3H -thymidine (5 Ci mmol^{-1} , Amersham) was added to give a final concentration of $1 \mu\text{Ci ml}^{-1}$ and incubated for a further 30 min. The medium was then removed and the cells were lysed with 1% sodium dodecyl sulphate after washing with phosphate-buffered saline (PBS). The lysate was treated with cold 5% trichloroacetic acid (TCA) and the precipitate collected on to nitrocellulose filters. The radioactivity was determined by liquid scintillation counting. The amount of radioactivity incorporated into the control cells was 1.05×10^5 c.p.m. per 10^6 cells.

of Fig. 4 with Fig. 2 indicated that there was no DNA repair under the conditions of our experiments. Instead, the DNA was fragmented further at concentrations greater than $0.1 \mu\text{g ml}^{-1}$ of actinomycin D. These data suggest that breakage of DNA by the drug at concentrations greater than $0.1 \mu\text{g ml}^{-1}$ is irreversible. This irreversibility could, however, be due to persistence of the drug in these cells since no information on the elution profile of actinomycin D from these cells is available.

The mechanism of cellular DNA breakage by treatment with actinomycin D is not known. It is possible that *in vivo* binding of this drug to DNA induces distortion in the helix⁷ such that attack by nucleases is facilitated. This suggestion is compatible

Fig. 2 Human KB cells prelabelled with ^3H -thymidine ($0.5 \mu\text{Ci ml}^{-1}$) for 12 h were treated with actinomycin D for 3 h as described in Fig. 1. The cells were trypsinised, washed and resuspended in PBS. About 2×10^4 – 4×10^4 of them were layered on to a 0.5 ml lysing solution containing 0.5 M NaOH, 0.2% SDS, and 0.01 M ethylenediaminetetraacetic acid (EDTA) on top of a 5–20% alkaline sucrose gradient containing 0.3 M NaOH, 0.01% SDS, 0.001 M EDTA. They were left to lyse for 12 h, and then centrifuged using a SW27.1 rotor in a Beckman ultracentrifuge at 20,000 r.p.m. for 6.5 h at 20°C . One-hundred-drop fractions were collected from the bottom of the tube. Radioactivity in each fraction was determined after cold TCA precipitation. Actinomycin D concentration ($\mu\text{g ml}^{-1}$): \circ , 0; \bullet , 0.1 (0.1 also similar to 0.01); Δ , 1; \square , 10; \blacksquare , 100. (Direction of centrifugation from left to right.)

Fig. 3 The cells were prelabelled as described in Fig. 2 and incubated in the presence of actinomycin D at a concentration of $10 \mu\text{g ml}^{-1}$ for the indicated times. The DNA was analysed by alkaline sucrose gradient centrifugation as in Fig. 2. Duration of treatment (h): \circ , 0; \bullet , 1; Δ , 2.5; \blacktriangle , 10.

Table 1 Effect of various concentrations of actinomycin D on cell survival

.1	0
1	0
10	0
100	0

Triplicate aliquots of 250 cells in 3 ml of α MEM plus 10% FCS were seeded in 60 \times 15 mm Flacon tissue culture dishes and allowed to attach and grow overnight. The medium was replaced by fresh medium containing the given concentration of actinomycin D. After 3 h of incubation, the cells were washed and growth medium was added. The number of colonies per plate was determined after 6 d of growth.

Fig. 4 The cells were prelabelled as described in Fig. 2 and incubated in the presence of actinomycin D for 3 h. The medium was removed and the cells were washed with 2×10 ml medium every 30 min for 2.5 h and incubated for 10 h further. The DNA was then analysed by alkaline sucrose gradient centrifugation. Actinomycin D concentration ($\mu\text{g ml}^{-1}$): \circ , 0; \bullet , 0.1; Δ , 1; \blacktriangle , 10.

with the fact that the DNA breakage induced by actinomycin D has not been observed *in vitro*^{8,9}.

Actinomycin D, at various concentrations, has been used to inhibit RNA synthesis and to examine the effects of this inhibition on other cellular functions. Data presented here and elsewhere¹⁰ suggest that caution is necessary in the interpretation of results obtained in such studies and that the fragmentation of the genome and its effects on cellular functions must be considered concomitantly. Furthermore, it appears that this drug

interferes with DNA as well as RNA metabolism in mammalian cells. Recently, it has been reported that initiation of protein synthesis is also inhibited¹¹. Thus, this drug may have more diverse effects on metabolic processes than is generally assumed.

Potential of phytomitogens action by neuraminidase and basic polypeptides

TREATMENT of lymphocytes with neuraminidase enhances their blastogenic response to some antigens and mitogens¹, increases their lectin-induced agglutinability^{2,3}, antigenicity and immunogenicity^{4,5}, alters their homing properties⁶ and renders the cells highly susceptible to the cytolytic effects of alloantibody and complement^{7,8}. These changes might result from the exposure of new sites on the cell surface^{2,3,9}, a reduction in the net surface charge of the cells or a combination of the two effects. Polycations agglutinate different cell types¹⁰⁻¹² and markedly reduce their anodic electrophoretic mobility¹⁰. In order to study the effect of cell surface charge on lymphocyte blastogenic response to phytomitogens the effect of polycations on this process was compared with that of neuraminidase.

The stimulation of ³H-uridine incorporation into RNA in rat lymph node lymphocytes, induced by con A (Fig. 1) and by phytohaemagglutinin (PHA) (Fig. 2), was enhanced after treatment of the cells with neuraminidase. In the experimental conditions, outlined in the legend to Fig. 1, 2.2 μg of sialic acid is released per 10^8 cells. This is equal to the total amount of sialic acid which can be released by neuraminidase action. The enhancing effect of neuraminidase was more apparent upon treatment of the cells with low concentrations of the phytomitogens. Like neuraminidase, basic polypeptides were also found to enhance blastogenesis induced by phytomitogens. Poly-L-ornithine and Poly-D-lysine were used in this study as they are resistant to degradation by proteolytic enzymes¹³. As shown in Fig. 3a, poly-L-ornithine enhances the stimulation of ³H-uridine incorporation into RNA in rat lymph node lymphocytes induced by con A. A similar effect was obtained upon addition of poly-D-lysine (Fig. 3b). Poly-L-ornithine also enhanced the stimulation of ³H-uridine incorporation into RNA in rat lymphocytes induced by PHA (Fig. 4). The stimulation of ³H-thymidine incorporation into DNA in rat lymph node lymphocytes, induced by con A and by PHA was also enhanced by poly-L-ornithine. The extent of ³H-thymidine

incorporation (c.p.m. \pm s.e.) into control, con A ($0.5 \mu\text{g ml}^{-1}$) or PHA ($0.5 \mu\text{g ml}^{-1}$)-treated rat lymphocytes, after incubation for 48 h, was 800 ± 79 , $32,590 \pm 3,170$ and $33,710 \pm 6,010$, respectively. ^3H -thymidine incorporation into similar cultures incubated in the presence of poly-L-ornithine ($1 \mu\text{g ml}^{-1}$) was 742 ± 44 , $62,970 \pm 7,190$ and $80,260 \pm 5,680$, respectively. The basic polypeptides alone did not stimulate the cells. In the experimental conditions outlined in Fig. 3a, poly-L-ornithine did not enhance the response of neuraminidase-treated cells to con A. As it seemed possible that the effects caused by neuraminidase and by the basic polypeptides might result from an increase in the binding of the lectins to the lymphocytes, I investigated this possibility. Rat lymph node lymphocytes ($5 \times 10^6 \text{ ml}^{-1}$ Dulbecco's modified Eagle's medium, supplemented

Fig. 1 Effect of neuraminidase on the response of rat lymphocytes to con A. Wistar rat lymph node lymphocytes ($10^6 \text{ cells ml}^{-1}$ PBS) were incubated with *Vibrio comma* neuraminidase (Behringwerke AG) (50 U ml^{-1}) for 30 min at 37°C . The cells were then washed and suspended ($5 \times 10^6 \text{ ml}^{-1}$) in Dulbecco's modified Eagle's medium, supplemented with horse serum (2%) and incubated as previously described²³. ^3H -Uridine incorporation was determined after incubation for 24 h. Con A, twice crystallised (Miles-Yeda) was used. Results are expressed as the mean \pm s.e. of triplicate cultures. \circ , Neuraminidase-treated cells; \bullet , control cells.

with horse serum (2%)) were incubated with ^{63}Ni -con A ($1 \mu\text{g ml}^{-1}$) in the absence and presence of poly-L-ornithine ($2 \mu\text{g ml}^{-1}$) at 37°C for 2 h. The specific binding of ^{63}Ni -con A to the cells was determined as previously described¹⁴. In these conditions, 48,000 molecules of con A were bound per cell in the control experiment and neither neuraminidase nor poly-L-ornithine had any effect on the extent of lectin binding.

In contrast to our finding that neuraminidase enhances the response of rat lymph node lymphocytes to PHA, other investigators have found that neuraminidase does not change the response of human lymphocytes to PHA¹ and inhibits PHA-absorptive capacity and PHA response of mouse spleen cells¹⁵. The discrepancies between the data obtained by different groups may be due to species differ-

Fig. 2 Effect of neuraminidase on the response of rat lymphocytes to PHA. For experimental details see legend to Fig. 1. Purified PHA from Wellcome was used. \circ , Neuraminidase-treated cells; \bullet , control cells.

ences and to the different doses of neuraminidase and PHA used in the various studies. It has been suggested that cross linkage and aggregation of specific membrane sites may be involved in the triggering of lymphocytes to undergo blastogenesis¹⁶⁻¹⁸. Aggregation of membrane sites (most probably glycoproteins) induced by lectins, occurs when the balance of forces favouring aggregation overcomes those which oppose it, like charge repulsion forces. The overall net sur-

Fig. 3 Effect of basic polypeptides on the response of rat lymphocytes to con A. Cells were cultured in the presence of **a**, poly-L-ornithine (average degree of polymerisation (DP) = 340) or **b**, poly-D-lysine (DP = 380). \circ , In the presence of con A ($1 \mu\text{g ml}^{-1}$); \bullet , control.

face charge of the lymphocyte is negative¹⁹ but little is known about the net charge of individual glycoproteins of the lymphocyte membrane. Glycophorin is a glycoprotein isolated from red cell ghost which carries the receptors for the plant lectins PHA and wheat germ agglutinin and contains 60% carbohydrate and 25% sialic acid by weight^{20,21}. If the lymphocyte receptors for con A and PHA were of a similar chemical nature, it might be expected that both neuraminidase treatment and polycations would facilitate their lectin-induced aggregation, by reducing charge repulsion. The enhancing effect of neuraminidase and basic polyamino acids on phytomitogens-induced transformation might also result from an increase in cell aggregation induced by either of these agents. Cell contact has been

shown to increase mitogen-stimulation of lymphocytes²². Neuraminidase treatment has a marked effect also on some cellular properties of non-lymphoid cells^{23,24}. It might be of interest to compare the effect of neuraminidase with that of polycations in a variety of biological systems. This approach might help to elucidate whether an observed effect induced by neuraminidase results primarily from a reduction in the surface charge or results from exposure of new sites on the cell membrane.

Blocking one-way maternal-foetal MLR

SIR,—The results of animal experiments^{1,2} show that enhancing or blocking antibodies may be at least partly responsible for the apparent lack of maternal immunological response to the paternally derived histocompatibility factors of the foetus. Youtananukorn and Matangkasombut³ used peripheral blood from normal *post partum* women to demonstrate that migration inhibition of maternal leukocytes occurred in the presence of pooled placental antigens. This response was completely blocked in the presence of autologous plasma but was unaffected by plasma from unrelated *post partum* women. We have used the one-way mixed lymphocyte reaction (MLR) between maternal (responding) and mitomycin-treated (stimulating) foetal cells obtained from cord blood to investigate the possible blocking effect of autologous maternal plasma.

Peripheral venous blood samples were collected at the end of labour from 12 women who had normal pregnancies and labours. Samples of cord blood were obtained at the same time, taking care to avoid contamination with maternal blood. Lymphocytes were separated from the heparinised blood samples by erythrocyte sedimentation in Plasmagel (Roger Bellon Laboratories). Cord blood lymphocytes were incubated at a concentration of $10 \times 10^6 \text{ ml}^{-1}$ in mitomycin C ($25 \mu\text{g ml}^{-1}$) for 20 min at 37°C and then washed three times in Eagle's MEM medium⁴. MLR

was then performed using the method previously described⁵. Results are summarised in the Table (figures in parentheses are standard deviations).

Autologous maternal plasma produced a significant inhibition of maternal lymphocyte transformation to stimulation by foetal lymphocytes in 3 out of 12 cases, while no significant effect was produced in control cultures containing homologous maternal plasma. In the presence of pooled male serum, a mixed lymphocyte reactivity of more than two occurred in only four out of twelve cases. This suggests the possibility that previous exposure of maternal lymphocytes to blocking factors *in vivo* might be partly responsible for their low responsiveness to foetal lymphocytes *in vitro*.

This might explain why autologous maternal plasma only produced a significant inhibition of response in those cases with a high mixed lymphocyte reactivity. It would also account for the apparent discrepancy between our findings and those of Youtananukorn and Matangkasombut³, since there might be different mechanisms whereby blocking factors produce their effects on lymphocyte transformation and leukocyte migration inhibition.

On the origins of molecular biology

SIR,—We wish to respond to the *Nature* supplement of April 26 entitled, "Molecular Biology Comes of Age". This gives the misleading impression that a specific date¹ can be placed on the birth of molecular biology. We suggest there are earlier origins for a true molecular biology.

In 1867 Spencer wrote in *Principles of Biology*:

"We have seen it to be a necessary inference from various orders of facts, that organisms are built up of certain highly-complex molecules which we distinguish as physiological units—each kind of organism being built up of physiological units peculiar to itself."

Forerunners of present concepts of molecular biology were proposed in the period 1860–1910 by Karl Nageli

Table 1 Results of the one-way MLR

0.8	524 (147)	346 (46)	66	NS	536 (148)	102	NS
3.8	2,007 (601)	572 (227)	29	0.02–0.05	1,242 (1,194)	62	NS

3.25×10^6 maternal (responding) and 3.25×10^6 foetal (stimulating) cells were cultured in 3 ml of Eagle's MEM medium (pH 7.2) enriched with 1 ml of 2 mM L-glutamine per 100 ml, for 7 d. Test cultures (in triplicate) contained 15% complement-inactivated autologous maternal plasma. Two sets of control cultures (each in triplicate) contained 15% complement-inactivated homologous maternal plasma, and 15% pooled male serum respectively. Maternal and cord blood lymphocytes were cultured separately in triplicate, to assess spontaneous transformation. Mixed lymphocyte reactivity is expressed as the ratio of the mean of the triplicate counts of the mixed cultures to the mean of the triplicate counts of the separate maternal and foetal cell cultures. The effects of autologous and homologous maternal plasma are expressed as percentages of the ratio of the mean triplicate counts of the mixed cell cultures in autologous and homologous plasma respectively, to the mean of the triplicate counts of the mixed cell cultures in pooled male serum. NS, Not significant.

(quoted in ref. 3), August Weismann⁴, Edmund Wilson⁵ and Hugo de Vries⁶, among others.

The early origins of molecular biology discussed by Gunther Stent⁷ and others emphasise the desire to apply laws much like those of physics to biology. In this regard, Erwin Schrodinger's book *What is Life?*⁸ was influential. Fifteen years before the publication of Schrodinger's book, the well-known biologist Edmund Wilson wrote a book with a similar intention entitled *The Physical Basis of Life*⁹.

Whereas a preoccupation with physics may have motivated the so-called "phage group"¹⁰ there was a separate origin for the application of physicochemical methods to studies of the structures of biological molecules¹¹. W. Astbury, an X-ray crystallographer, clearly played a major part in this, and indeed was the first to coin the term molecular biology¹². In addition, it is not generally realised that in 1949 Sven Furberg, a Norwegian graduate student in the laboratory of J. D. Bernal, was the first to propose a helical structure for DNA, albeit single-stranded, on the basis of X-ray studies on nucleosides¹³.

We thus conclude that it is somewhat difficult to set a precise date for the origin of molecular biology, but we presume that by April 25, 1953, molecular biology had already come of age.

DNA synthesis in plants

SIR,—Buchowicz¹ reports "that incorporation of thymidine into DNA of germinating wheat seeds begins only after some preliminary activation of RNA synthesis is completed, implying an RNA-dependent DNA synthesis".

I do not agree with this conclusion. Indeed, it has only been demonstrated that RNA synthesis precedes DNA synthesis^{2,3} and that inhibition of protein synthesis between 0 and 9 h results in a complete suppression of DNA synthesis. These essential proteins are probably coded for by pre-formed mRNA^{4,5}. Thus, it is not at all evident that DNA synthesis is dependent on RNA in this way. Thymidine is not incorporated into DNA before a lag period in germinating wheat because, as in other plants, the phosphorylating enzymes are lacking in dry seeds^{6,7}. They become detectable a few hours before the onset of DNA synthesis^{7,8}. In contrast, uridine can be phosphorylated by extracts of dry seeds^{8,9}.

I wish to draw your attention to my interpretation of Dr Buchowicz's results. A prerequisite to check whether the cytoplasm may be an early site of nuclear DNA synthesis is to obtain a cytoplasmic fraction free of nuclear contamination. I have frequently obtained significant ¹⁴C-thymidine labellings in similar 'cytoplasmic fractions' with radish seedlings, but all the electron microscope controls I have performed have revealed that nuclei were broken in the 1,000g pellet, and that successive 15,000g and 27,000g pellets still contained chromatin. The difficulty of isolating unbroken plant nuclei is well known amongst plant biochemists, and this is the reason why I believe that most of the radioactivity detected by Dr Buchowicz in his cytoplasmic fraction is of nuclear origin.

The higher specific activity of the cytoplasmic fraction can be explained if we assume¹⁰ that newly synthesised, short, DNA fragments are probably more easily released from broken nuclei than highly polymerised DNA from chromatin. One way to check whether the cytoplasmic fraction is free of nuclear contamination would

be to assay this fraction for nuclear enzymatic activities such as RNA polymerase.

Yours faithfully,

M. DELSENY

DR BUCHOWICZ REPLIES: I was interested to learn that Dr Delseny had observed similar labelling of cytoplasmic DNA in radish seedlings.

The possibility of nuclear contamination of the 'cytoplasmic fraction' has not been overlooked in my letter¹. Instead, it was found insignificant, as the cytoplasmic radioactivity dropped when the possible source of contamination, radioactivity of nuclear DNA, increased. The comments concerning the dependence of DNA synthesis on thymidine kinase activity are obviously important. Nevertheless, the DNA synthesis would proceed without the participation of thymidine kinase (deriving TMP from UMP reduction and methylation) if not limited by other factors. It is known, however, that other precursors as well as thymidine are not incorporated into DNA at early germination stages, in spite of the fact that enzymes catalysing UMP synthesis² and reduction³ are active. It seemed, therefore, justified to point out that the initiation of DNA synthesis in awakening wheat embryo may depend on the appearance of a newly synthesised RNA fraction.

Pergamon Review Journals in the Life Sciences

In the interest of expediting publication and wider dissemination of the many important review articles published in the various Pergamon publications specialising in the publication of reviews, such as our many Progress and Advances series hitherto published in book format, these will, with effect from 1st January 1975, be available in journal form on subscription. Subscribers will receive a free annual subject index to each volume. Booksellers and librarians are invited to convert their standing order into a subscription order. The 1975 subscription prices for some of our Review journals are given below. Please write for the full Pergamon Journals 1975 Official Subscription Price List.

ADVANCES IN ENZYME REGULATION

Editor: G. Weber

Annual subscription US\$40

'... successful in reaching its goal of advancing a few steps ahead of the general front of mammalian enzyme regulation studies'

The Cancer Bulletin on Volume 10

PROGRESS IN BIOPHYSICS AND MOLECULAR BIOLOGY

Editors: J.A.V. Butler & D. Noble

Annual subscription US\$70

'These volumes help the reader to know the current status of the subject. They help the workers to clarify many areas of confusion in their field. They also open vast avenues for further work and provide guidelines for the future workers in the field who would find the series indispensable'

Medical Book News

PROGRESS IN NEUROBIOLOGY

Editors: G.A. Kerkut & J.W. Phillis

Annual subscription US\$40

'... the journal should prove to be an extremely valuable reference source'

Neurology

PROTIDES OF THE BIOLOGICAL FLUIDS

Editor: H. Peeters

Annual subscription US\$60

New Review Journals Starting January 1975

INTERSCIENCE

CHROMOSOMES TODAY, Volume 4

Edited by **J. Wahrman** and **K. R. Lewis**, both of the Hebrew University of Jerusalem and the University of Oxford.

This volume is the fourth in the series, being the proceedings of the International Chromosome Conferences inaugurated by C. D. Darlington and K. R. Lewis held at the Botany School and Magdalen College, Oxford, in 1964, 1967 and 1970.

July 1974 456 pages £14.00
Published by Israel Universities Press, and distributed by John Wiley & Sons Ltd.

PYRIDINE SUPPLEMENT IN FOUR PARTS, Part 2

Edited by **R. A. Abramovitch**, University of Alabama.

Collects, summarizes, and reviews the enormous amount of work in the field of pyridine chemistry since the last coverage of 1959. (*Chemistry of Heterocyclic Compounds, Volume 14*).

March 1974 680 pages £31.00

FUNDAMENTALS OF PALEONTOLOGY, Volume 5

Edited by **V. E. Ruzhentsev**, and **Yu A. Orlov**, Academy of Sciences of the USSR.

A comprehensive survey of the main groups of fossil Cephalopoda, with emphasis on an Onto-Phylogenetic classification as the most valuable guideline in stratigraphic determinations. Full morphological descriptions, systematic treatment, biostratigraphic data. (*Translated from the Russian*).

July 1974 896 pages £23.40
Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley & Sons Ltd.

CONTROL OF THE ONSET OF PUBERTY

Edited by **Melvin M. Grumbach, M.D.**, University of California, San Francisco, **Gilman D. Grave, M.D.**, and **Florence E. Mayer, M.D.**, both of the National Institute of Child Health and Human Development.

Records proceedings of a conference held in October 1972 and sponsored by the Growth and Development Branch of the National Institute of Child Health and Human Development. Animal experimentalists and clinical investigators compare and contrast findings and report their current research.

May 1974 510 pages £12.00

HORIZONS IN PERINATAL RESEARCH: Implications for Clinical Care

Edited by **Norman Kretchmer** and **Eileen G. Hasselmeier**.

A symposium by the Perinatal Biology and Infant Mortality Branch, National Institute of Child Health and Human Development, held December 6-9, 1970, Stanford, California. Authorities discuss their investigative activities as well as directions for future research. Emphasis is on equal concern for both infant and mother and on research with cross-disciplinary approaches that range from molecular biology to epidemiology. Concludes that separation between paediatrics and obstetrics must disappear.

May 1974 214 pages £8.25

MICROCIRCULATION

Edited by **Mary P. Wiedeman**, Temple University School of Medicine.

Innovative and provocative articles trace the history and development of *in vivo* microscopic observations of small blood vessels as well as microvascular structure and function. Includes classic papers by Harvey and Krogh as well as seldom seen papers by van Leeuwenhoek and T. Wharton Jones. (*Benchmark Papers in Human Physiology*).

August 1974 442 pages £11.65
Published by Dowden, Hutchinson and Ross, Inc., and distributed by John Wiley & Sons Ltd.

LABORATORY MANUAL OF PETROGRAPHIC TECHNIQUES

By **Charles S. Hutchinson**, University of Malaya.

Brings together many of the commonly petrographic techniques that are generally applicable to igneous and metamorphic rocks. Stresses practical aspects: theoretical discussion is kept to a minimum.

May 1974 558 pages £10.60

THE ORCHIDS: Scientific Studies

Edited by **Carl L. Withner**, Brooklyn College and Brooklyn Botanic Garden.

All significant information on orchids—what is known as well as research problems—is compiled in this informative volume for both botanists and orchid fanciers. Discusses ecology and evolution, clonal propagation, and alkaloids; covers embryology in detail for the first time in English; and is a handy reference source for chromosome counts and hybrid genus names.

August 1974 618 pages £12.00

PHYSICS OF MESOPHERIC (NOCTILUCENT) CLOUDS

Edited by **M. A. Dirikis**, Academy of Sciences, Latvian SSR.

This book, edited by one of the foremost experts on noctilucent clouds, deals with all aspects of this extraordinary phenomenon: the history of the discovery and of research on noctilucent clouds. (*Translated from the Russian*).

April 1974 164 pages £7.50
Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley & Sons Ltd.

ELECTROENCEPHALOGRAPHY (EEG) OF HUMAN SLEEP: Clinical Applications

By **Robert L. Williams, M.D.**, **Ismet Maracan, M.D.**, and **Carolyn J. Hirsch**.

Presents an atlas of the EEG of human sleep that will serve as a convenient reference for the clinician. Displays and describes, as completely and systematically as possible, the characteristics of the EEG of human sleep as seen at all ages from birth to old age.

May 1974 186 pages £8.00

reviews

Scientific laws and logic

The Structure of Scientific Inference. By Mary Hesse. Pp. vii+309. (Macmillan: London and Basingstoke, April 1974.) £5.95.

IN this book Dr Hesse develops a logic of science. She is concerned for the most part with inference. One might expect however, that some account of scientific theories would be adopted as a starting point because theories are involved in most scientific inference. The account of theories will to some extent determine the characteristic patterns of inference. For example, if it is held that theories are partially interpreted deductive systems, then inference from theory to observable consequence will be deductive. In common with an increasing number of contemporary writers Dr Hesse rejects this formalist view. As an alternative a network model of theories is proposed (page 4):

"Briefly, the model interprets a scientific theory in terms of a network of concepts related by laws, in which only pragmatic and relative distinctions can be made between 'theoretical' and 'observational'. Some lawlike statements of the theory can be tested relatively directly by observation, but which these are may depend on the current state of the whole theory and whether an observation statement is accepted as 'true' or 'false' in any given case may also depend on the coherence of the observation statement with the rest of the currently accepted theory."

This implies that the acceptance or rejection of a given observation statement may depend on current theoretical considerations. These may change, and so we may come to reject as false a statement previously accepted as true. Dr Hesse mentions that the network model owes much to Quine and Duhem. This is clearly true.

The Quine-Duhem thesis and related views are by no means unproblematical. Suppose we want to reject as false the observation statement "The individual x_1 is red" which we had previously accepted. If x_1 and all those other individuals x_2, x_3, \dots which were previously said to be red still retain the same colour as before, then if x_1 is no longer red then neither are x_2, x_3, \dots , on the assumption that all the individuals have the same colour, hence nothing is red. If necessary some new word could be invented to describe this colour. Dr Hesse is not committed to this trivial view because on her account of how we learn to use words such as

red we recognise that individuals are similar to each other to an unspecified degree. Thus theoretical considerations may suggest that after all x_1 is not sufficiently similar to x_2, x_3, \dots to be called red. But if 'similar' is always taken to be 'similar in a given respect', as it is by Popper, then this implies that there are no degrees of similarity and also that 'similar' is transitive. There are of course, differences within the class of red objects in that there are shades of red, but degrees of redness in this sense does not imply degrees of similarity among red objects. Dr Hesse discusses similarity at some length; in particular she defends her account against a Popperian view. It is unfortunately not possible to do justice to her arguments in a short review.

Dr Hesse's account of theories leads her to discuss inductive and analogical inference; this involves a discussion of arguments from particular to general and from particular to particular. In the context of a logic of science these concern the confirmation of theories and predictions by evidence. Dr Hesse does not attempt to justify non-deductive inference, but rather she gives an explication of the intuitive inductive rules used by scientists. An explication is the process of formulating precise rules of use, possibly expressed in a formalised system, for an imprecise concept which is used in some domain of discourse. The explication may suggest revisions in the use of the concept in question or in the use of related concepts. Dr Hesse sees the problem of induction as falling into two parts: (1) to formulate a set of inductive rules; (2) to formalise these. She concentrates on (2). In the light of the network model she suggests that the axioms of probability are best adapted to explicate inductive practices. Probability is interpreted in the personalist sense as degree of rational belief. Thus the answer to this problem of induction is an acceptable probabilistic confirmation theory.

At least two problems confront a proponent of a probabilistic confirmation theory. First, it is necessary to show that some adequate resolution of the paradoxes of confirmation is possible within the theory. Dr Hesse takes the so-called transitivity paradox to be one of the most general and powerful paradoxes. It suggests that confirmation is not always transitive. We are not, therefore always able to assume that the degree of confirmation of a

theory by certain evidence is passed on to the predictions of the theory. In order to account for our confidence in predictions Dr Hesse interprets theoretical inference as inference from evidence to prediction bypassing theory. The inference is taken to be analogical and the role of the theory is to make explicit the analogy between evidence and prediction. This is a most interesting suggestion.

Second, if a probabilistic confirmation theory is to account for the confirmation of laws, it may be thought necessary to justify the restriction of the scope of laws to finite domains. This restriction, which is a consequence of the explication, is necessary because, given that the language is infinite and that there are no *a priori* reasons for assigning finite initial probability to any finite subset of possible universal generalisations, then no finite amount of evidence will raise the probability of such a generalisation above the initial value of zero required by the probability axioms. Popper and Lakatos have taken this to be a fundamental objection to Carnap's confirmation theory. But Dr Hesse argues that laws are expressed by generalisations of finite scope because it is unreasonable to believe that unrestricted generalisations have any chance of being true and hence that zero probability is appropriate for such generalisations. If restricted generalisations may be assigned non-zero probability, then we would expect that the reason why unrestricted generalisations have zero probability concerns the fact that their scope is unrestricted. But according to Dr Hesse (page 181):

"This is not so much because such a belief covers an infinite number of instances, but rather because it may not be reasonable to believe that U [a Universal generalisation] states a law accurately even in one instance."

If this is true, then it seems to follow that it is unreasonable to believe that a finite generalisation expresses a law accurately. It is not however, obvious that it is reasonable for scientists to be convinced (probability=1) that all universal generalisations are false. If it is held that some laws are expressed by universal generalisations, then we may be inclined to reject an explication which has as a consequence that these laws have zero probability.

Although I think that it is possible to give further arguments in favour of these criticisms of Dr Hesse's logic of science, this is not to say that Dr

Chemistry & Biochemistry from Longman

The Chemical Economy

B G Reuben and M L Burstall

A wide ranging survey of the development and present structure of the chemical industry. The book shows interactions between science and economics that shape many of the material aspects of our society

£6.95 net.

Introduction to the Soil Ecosystem

B N Richards

This book emphasises the role of soil organisms (and in particular that of microorganisms) in the regulation of terrestrial ecosystems. It provides a proper perspective for consideration of the place of soil organisms in the structure and functioning of ecological systems.

£2.95 net.

Companion to Biochemistry

Selected topics for further study.

Edited by A T Bull, J R Lagnado, J O Thomas, and K F Tipton

This book provides the advanced undergraduate or M.Sc. student with up-to-date accounts of those topics likely to form the major part of his course.

£7.00 net.

Comprehensible Biochemistry

Michael Yudkin and Robin Offord

Comprehensible Biochemistry is a text book designed for undergraduate students of the subject - not only those reading honours biochemistry but also those for whom biochemistry is an important subsidiary study. The student will find the clear style and thoughtful presentation of this book a refreshing change from more pedestrian treatments.

£4.95 net.

Plant Cell Structure and Metabolism

J L Hall, T J Flowers and R M Roberts

An up-to-date treatment of plant metabolism in relation to cell structure. The text assumes a basic knowledge of chemistry and biology and is suitable for undergraduate students of plant and biology sciences, postgraduate students of plant biochemistry and physiology.

£4.95 net.

Longman
1724 - 1974

Hesse's book is not an interesting and original contribution to the philosophy of science. It is therefore to be recommended to the advanced student, though to one who is not familiar with the subject it may prove a little difficult.

JOHN FORGE

Television tomorrow

Television: Technology and Cultural Form. By Raymond Williams. Pp. 160. (Fontana/Collins: London, 1974.) 45p.

WHEN Raymond Williams was television critic of *The Listener*, he tried to appraise television as a phenomenon in spite of the convention among reviewers that what counts are programmes, as isolated units. In this book he is able to stand back and take a very long view. Television—what is it? Technology, or social force? What does the experience of watching television consist of? How did the institutions of broadcasting develop out of the technology and what kinds of institutions may arise to serve up television in its new forms—video cassettes, cable television, international broadcasting?

The author (now reader in drama at Oxford) concludes that there was nothing inevitable in television's emergence as a form of mass entertainment consumed by individuals in the privacy of their homes. He does not swallow the argument that "I Love Lucy" was as inherent in the vacuum tube as some believe the atomic bomb was in the splitting of the atom. Television, he maintains, emerged in its present form because it was under the control of the broadcasting institutions that had developed radio. And radio's growth was determined, even forced, by the equipment manufacturing industry. But between the two media (it is possible to use the word in the plural) there is a profound difference. Radio is cheap. Television is expensive. And the contradiction remains. No country, even the United Kingdom, has satisfactorily solved it. How to recover the enormous costs of television from a mass audience of individual viewers?

Mr. Williams devotes a long chapter to the comparative incidence of various types of television programmes on five television channels—three British and two American—during a single week. The results are hardly surprising. (BBC1 led the pack in public affairs discussions, with 8.3 hours, while Channel 7 in San Francisco was tops in commercials, with 18.4 hours.) A mild point made by the author is that the formal category of programme matters less than its manner. A serious documentary may be trivialised. A panel quiz game may illuminate rela-

tionships between husband and wife.

The most interesting thesis of Mr Williams's book, to my mind, is the idea that television is the whole package. He calls it "flow". The programmes, news and weather breaks, commercials, trailers for later programmes, the lot. By this standard, the BBC is full of commercials—for itself. He is amusing when he recounts the difficulty, in Miami, in trying to follow the plot of an old movie. Not only were the advertisements inserted more frequently as the viewer became hooked on the programme but there were added as well trailers of two other old films, to be shown on subsequent nights. He also observes that on the San Francisco channel, the news that some pharmaceutical companies had been accused of false advertising claims was part of the same news bulletin that contained a commercial for a pain killer.

Looking ahead, Mr Williams is worried by the paradox presented by the new technology. He sees the promise of cable (multi-channelled, wired) television and international satellite broadcasting as that of democratising communications, of bringing a new universal accessibility to television. Yet he sees (by looking back) that these developments could be stifled by existing broadcasting organisations, by international advertisers and governments. At the same time he sees that uncontrolled development of cable television could destroy what is good in national broadcasting. His main suggestion is that there should be more independent television production companies. These could diminish, without destroying, national broadcasting while providing content for cable systems to transmit. Cable he would have as a national utility.

There are a few quibbles one must make. Cable television will not be universally available in the United States by 1980. And it is unlikely to reach 30% of television homes in Britain by that time either. Its growth has been stopped dead, by restrictive rules and by shortage of investment capital. Similarly, the author's recommendation that proper international agreements on satellite television should not involve bodies with weighted voting (like Intelsat) is unrealistic. The fact is that, as the United Nations' experience has shown, a system of one vote to a country is a form of weighted voting itself, for it allows small countries a disproportionate influence from sheer numbers.

It is a pity that this book is not more readable for there is much in it that will interest media buffs. On the future of British Broadcasting, Lord Annan's committee should find it stimulating.

BRENDA MADDOX

Ciba Foundation Symposia (new series)

Civilization & Science: in Conflict or Collaboration?

Ciba Foundation Symposium 1
1973. 238 pages.
£ 2.70/US\$ 6.70/Dfl. 17.50.
Paperback edition.
ISBN 90 219 4027 2

'Here we have physicists, biologists, doctors, economists, philosophers, historians, sociologists, a psychologist, and a politician discussing *Civilization and Science: in Conflict or Collaboration?* The contributors come from all corners of the world: England, France, The United States, Canada, Holland, Switzerland, South Africa, India, Japan and Venezuela. Almost all the contributions are interesting, the discussions are lively, and the symposium is an outstanding success'.

The Times Literary Supplement

Physiology, Emotion & Psychosomatic Illness

Ciba Foundation Symposium 8
1972. 430 pages.
£ 8.15/US\$ 30.40/Dfl. 53.00.
ISBN 90 219 4009 4

Theoretical concepts of emotional states, and definition of terms; physiological, experiential and psychological mechanisms in the organization of affect, and possible correlations with brain structure; theoretical and animal models for studying behavioural responses to stress and psychosomatic phenomena in man; psychosomatic illnesses, including coronary artery disease, subarachnoid haemorrhage, obesity and asthma.

Medical Care of Prisoners and Detainees

Ciba Foundation Symposium 16
1973. 238 pages.
£ 4.70/US\$ 11.70/Dfl. 30.50.
ISBN 90 219 4017 5

Lawyers, psychiatrists, doctors, prison administrators, sociologists and others – from North America, Europe and North Africa – here discuss how legislation affecting the physical or mental health of people held in prisons and camps might be implemented and improved. The management of disturbed or violent offenders, experiments on prisoners, tension in camps and many other topics are covered. This report will arrest the attention not only of all those who look after prisoners professionally but also of everyone concerned about offenders and victims in the present world climate of violence.

Law and Ethics of A.I.D. and Embryo Transfer

Ciba Foundation Symposium 17
1973. 118 pages.
£ 2.30/US\$ 5.80/Dfl. 15.00.
ISBN 90 219 4018 3

'This record of the experiences and opinions of such a wide spectrum of distinguished men and women representing medicine, the law and the church in a single volume makes this publication one of outstanding importance. No one who is concerned with these new developments in relation to human reproduction should fail to read it. It is excellently produced....'

Journal of Obstetrics and Gynaecology

Medical Research Systems in Europe

Ciba Foundation Symposium 21
1973. 344 pages.
£ 6.60/US\$ 16.50/Dfl. 43.00.
ISBN 90 219 4022 1

This book describes how medical research is supported and organized in the various European countries and how such research is related to the different systems of medical education and of health care. It will enable medical research workers who must make decisions about travelling research fellowships or international collaborative research to understand the educational background and career structure of research workers in other countries. In addition, those responsible for formulating national research policy in the medical sciences will be able to learn from it about the mistakes and successful experiments in organization in different parts of Europe during the last 25 years.

Human Rights in Health

Ciba Foundation Symposium 23
1974. 314 pages.
£ 6.00/US\$ 15.00/Dfl. 39.00.
ISBN 90 219 4024 8

Safe water, enough food, protection against communicable disease, and the means of controlling fertility – it should be possible to give every human being access to these essentials of a healthy existence if present knowledge were appropriately applied. The thesis underlying this symposium is that these four objectives can be considered as basic human rights, and the contributors attempt to estimate the necessary costs and social changes and the effects on world development of converting these rights into realities.

Oxford Books – new and forthcoming

Our Future Inheritance

Choice or Chance?

Alun Jones and Walter F. Bodmer

Recent advances in genetics, biology, and medicine have important social, ethical, and legal implications as well as being of great scientific interest. This book, which is based on a study by a British Association working party, has its origin in a series of discussions among scientists, doctors, surgeons, lawyers, theologians, M.P.s, and social scientists. It is concerned with some of the most significant topics: artificial insemination and fertilization of humans; genetic screening and selective abortion; organ transplantation, genetic engineering and cloning. The authors have set out to present the issues dispassionately in a form that will be intelligible to the general public. £4 paper covers £1.25 *forthcoming*

Organizing for Science in Britain

Ian Varcoe

This book describes attempts by the British Government to organize and foster the organization of scientific research in pursuit of national industrial development in the present century. The author tells the story of the emergence of 'scientific and industrial' research during the First World War and the subsequent elaboration of the research council concept. He explains the organization of science within the Government, and considers the role and responsibilities of scientists in industry and the universities. £2.40 *Science and Engineering Policy Series*

Science and Policy

The International Stimulus

Alexander King

Research now accounts for a sizeable proportion of the gross national product of all industrialized countries, and funds for research and development come mainly from governments. Because the promise offered by new discovery is greater than the resources available, governments have created national policies and priorities. Furthermore, increasing scale and cost have encouraged the sharing of research internationally. This book sketches the evolution of such policies from an international viewpoint, outlines the main issues, and indicates future trends. £2.25 *Science and Engineering Policy Series*

Introduction to Control Theory

O. L. R. Jacobs

This book gives a uniform presentation of the main results of classical control theory, optimal control theory, non-linear methods, and stochastic control theory. The wide range of the book is achieved in reasonable compass by omitting extensive discussions of specific practical applications. The mathematical level is that of final-year undergraduate courses in engineering science, but the book is accessible to anybody with some knowledge of ordinary linear differential (or difference) equations, the elements of probability theory, complex numbers, and matrix algebra. Its value as a textbook is increased by a wide range of problems with answers, and, as a work of reference, by the extensive bibliography. £6.75 *forthcoming*

Dimensional Analysis for Engineers

Edward S. Taylor

This book provides a new and essentially non-mathematical approach to its subject, with many examples illustrating pitfalls and possibilities for making dimensional analysis more understandable and more useful in a wide variety of situations. While the approach can improve the understanding of many problems, it will be found most useful in tackling those which are either too complicated or too general for full analytical treatment. £5.75

Molecular Reaction Dynamics

R. D. Levine and R. B. Bernstein

This book deals with the molecular-level mechanisms of elementary chemical reactions, emphasizing the important role of binary collisions. The goal is an understanding of chemical and physical rate processes from the fundamental, microscopic point of view. Primary attention is devoted to the physical phenomena and their conceptual interpretation rather than to the details of experimental techniques or theories. Topics discussed in some detail include the dynamics of molecular collisions, potential-energy surfaces, reaction cross-sections, molecular and ion beam scattering, 'direct' and 'complex' modes of reaction, photo-fragmentation, energy partitioning, energy transfer, chemiluminescence, and chemical lasers. £5 *forthcoming*

Doctor meets patient

Therapeutics: From the Primitives to the 20th Century, with an Appendix—History of Dietetics. By Erwin H. Ackerknecht. Pp. x+194. (Hafner, Macmillan: New York; Collier Macmillan: London, January 1974.) £6.25.

MEDICAL historians have all too often shown greater interest in what doctors have written than in how they have treated their patients. They have studied medical ideas and theories rather than the ways these ideas have been applied. Certainly, theory fascinates more than praxis. Yet for the patient at least, praxis is the key medical activity, patients being far more concerned with what their physicians can do than with what they know.

Therapeutics is the point where doctor and patient meet. Nevertheless, such has been the neglect of this subject by medical historians that the last general history of therapeutics was published in 1877—a fact which makes Professor Ackerknecht's lucid and stimulating volume all the more welcome. First published in German in 1970, it has now been translated by the author, formerly Director of the Institute of Medical History at the University of Zürich. The book charts the therapeutic programmes and rationales of medicine from the Egyptians to the twentieth century. Ackerknecht's method involves analysis of the therapeutic writings of major medical figures in each particular age: the Hippocratics, Galen, Paracelsus, Sydenham, Laennec, Ehrlich, and so on. In addition, he refers frequently to the works of less well known doctors whose activities and thoughts were equally significant in defining the medical texture of each of his historical portraits. The result is a monograph which is crammed with facts and brimming with ideas.

It is difficult to summarise a book which is so wide ranging. Nevertheless, two recurrent themes should be mentioned. First, as Ackerknecht repeatedly demonstrates, medical theories have been far more flexible than medical therapeutics. Bloodletting, for instance, has been employed in many different settings. The primitives used it. The Greeks recommended it, as did the Indians. Bloodletting was practised in the Middle Ages, the Renaissance and the Enlightenment. In fact only in the middle of the nineteenth century did physicians begin to look critically at this traditional form of therapy. The therapy itself remained essentially unchanged, yet the rationale for this therapeutic procedure could be different for each particular age or culture setting. The same may be said for many other traditional therapies, such as purgatives, cathartics and emetics.

The second historical insight which Ackerknecht brings to bear on his subject concerns the nature of medical experience. In therapeutics, each doctor should be able to form independent evaluations of the effectiveness of his armamentarium. Unfortunately, experience often being no more than 'pseudo-experience', doctors have found that any particular therapeutic regimen yields precisely the results they expected it to. Patients rarely disappoint their physicians if they can help it.

Professor Ackerknecht explores the historical ramifications of these and many other themes in this splendid little book. A full appreciation of it requires some prior acquaintance with the general features of the history of medicine. This can be pleasantly acquired through Ackerknecht's *Short History of Medicine*, published in 1955 but still the best short introduction to the subject available. The remarkable range of his interests may be seen from some of his other contributions to the history of medicine: a biography of Rudolf Virchow, a study of French medicine in the first half of the nineteenth century, a monograph on malaria in the Upper Mississippi Valley, a short history of psychiatry, and a series of classic papers on primitive medicine. These works mark Erwin Ackerknecht as a true cosmopolitan and one of the outstanding medical historians of our time.

W. F. BYNUM

Rejecting behaviourism

The Psychology of Consciousness. By Robert E. Ornstein. Pp. xxi+247. (Freeman: San Francisco, 1972.) \$3.50.

THIS book represents a current swing away from behaviourist psychologies, in which consciousness is ignored or even denied. It criticises Western science, as being over-limited to sequential processes of reasoning at the cost of immediate intuitive understanding, associated with the Eastern approach to studying mind represented by the Chinese I Ching and the meditative and rhythmic exercises of yoga. Dr Ornstein tries to relate East and West, with the neurological notion that (in right handed people) the right cerebral hemisphere serves the artist and dreamer, while the left hemisphere serves sequential logical thinking and language. For this he refers to the important 'split brain' experiments of Roger Sperry, in which the fibres of the corpus callosum, normally joining the hemispheres, are sectioned in serious cases of epilepsy.

Ornstein suggests that the right-hemisphere Eastern culture and the left-hemisphere Western culture can be combined—to make better use of the brain as a whole. Is this a neurological alliance of C. P. Snow's Two Cultures?

Grassland Ecology and Wildlife Management

E. DUFFEY, M. G. MORRIS, J. SHEAIL,
L. K. WARD, D. A. WELLS and T. C. E. WELLS

July 1974: 0 412 12290 1: 304 pages:
tone and line illustrations: hardback:
£5.40

This book describes the distribution and ecology of lowland grasslands in Britain with special reference to their flora and fauna, history, and management for wildlife conservation. The maintenance and manipulation of grasslands for agricultural, scientific, conservation and recreational purposes requires an extensive knowledge of the responses of plants and animals to different treatments and disturbance factors. The book examines these in relation to the range of variation in lowland grassland ecosystems and to the known land-use history.

OUTLINE STUDIES IN BIOLOGY

The individual books in the Outline Studies in Biology Series present succinct, authoritative and up-to-date introductions to their subject. They supplement and extend main course texts, and because each book deals with only one topic the series offers the advantage of great flexibility of use.

Ornstein refers also to recent experiments on 'biofeedback', in which he has himself made interesting contributions on the control of automatic functions not normally under conscious control. There are also references to anthropological data on different ways that people categorise, describe and see things as evidence for the relativity and perhaps arbitrariness of what is accepted as knowledge.

The book starts by referring to Kuhn's scientific paradigms, as both giving stability to science and belief (analogous to the perceptual constancies) and also as limiting what we can see and understand. To Ornstein, behaviourism's rejection of consciousness, and logical positivism's rejection of statements not susceptible of strict 'scientific' verification as not meaningful, are examples of paradigms so narrow that important understanding is blinkered and lost. Although one may sympathise with Ornstein's dissatisfaction with behaviourism as a paradigm for psychology (however useful it may have been to concentrate experiments on technically feasible enquiry) he does not lay siege with much fact or rigour, except indeed to point to consciousness as a fact that it is absurd to ignore. He seems in places to follow Aldous Huxley in regarding the nervous system as doing not much more than filtering experience—quoting with approval Huxley's remark: "Mind at large has to be funnelled through the reducing valve of the brain and nervous system. What comes out at the other end is a measly trifle of the kind of consciousness which will help us to stay alive on the surface of this particular planet". This is, however, a view far opposed to current theories of perception, as active construction from limited data signalled by the senses—but which Ornstein also espouses. There seems to be a lack of consistency in the book on these questions; but its aim is evidently to loosen what Ornstein regards as constraining bonds of current theories of brain function, rather than attempt at this time to produce a conceptual synthesis, or a consistent working paradigm for psychology. It does have the merit of asking some awkward questions, with suggestions that answers might be found in strange places.

Here we come to the nub of the problem: to the Western reader without experience of 'meditation', the descriptions of conscious states and so on are difficult to comprehend or even to take seriously; but is this because of restricting limits of our experience, and paradigms of what should constitute science? Ornstein puts the matter cogently (page 6): "Science as a mode of knowing involves a limitation on enquiry. The essence of good experiment is successful exclusion". And

later (page 100), reversing the case from a non-technological to a Western society: "Our peasant . . . cannot see why, if it is indeed possible (as we claim) to fly to the planets, he cannot do it now in his own terms . . . When he fails, he will likely come to believe that 'space flight' is really an impossibility, that any one who claims it to be possible is simply gullible, 'unscientific', or even a liar . . . It is similar tendencies in ourselves which we, as Western students of psychology, may need to overcome in investigating an area which is so new, so spectacular, and so unknown to us . . . We should not ignore 'Eastern science' because of its imbalances, or because of the misinterpretations heaped around it". This book presents a case with honesty and with learning which is nevertheless in parts very difficult to comprehend, let alone judge. But if the case were valid, surely this is just what we might expect!

RICHARD L. GREGORY

Highly strung

Development and Regeneration in the Nervous System. Edited by R. M. Gaze and M. J. Keating. Pp 105-193. (British Medical Bulletin Vol. 30, No. 2.) (British Council: London, May 1974.) UK £2.25; elsewhere £2.50.

THE title of this bulletin is most appropriate for the two thirds concerned with studies on the nervous systems of animals. Research on nerve specificity and regeneration using histology, electron microscopy, surgery and electrophysiology is described. The rest of the bulletin is concerned with medical and social topics to which the physiological studies should be relevant: the epidemiology of spina bifida, the effect of malnutrition on intelligence, the educability of the subnormal. Though the gap between the two groups is to some extent bridged by Balács's description of metabolic influences on brain development in both animals and men, the difference in treatment is marked. This is inevitable as long as the relation between nervous connections and learning is unknown. Only Cragg speculates on this, discussing his work on synaptic patterns in mentally deficient mice.

The physiological articles are mostly excellent reviews of areas of research. Gaze's article on neuronal specificity in goldfish is particularly lucid. I found the other articles slightly less satisfactory, because of the relative paucity of facts. An exception is Bower's fascinating review on the innate abilities of newborn babies and how these develop. The bulletin is well presented and will be invaluable for those interested in the wide fields it covers.

GILLIAN MOORE

$$G = \frac{Mmc}{r^2}$$

**a NEW ROAD TO RELATIVITY—
DISCOVERED by MORRIS REDMAN SPIVACK**
4th Edition, 1974. © by M. R. Spivack 1967, '68 & '72.

G—gravitational attraction. **M** is one mass, in grams, **m** is another. **c** is the velocity of light (cm/s). **r**—radius between **M** and **m**.

In this revolutionary formula (the velocity of light being identical with the velocity of transmission of the gravitational impulse) **c** represents the gravitational field, while **Mm** represents the inertial field. Thus I bring Einstein's principle of equivalence into Newton's law of gravitation! (**c** = 2 in the numerator) (but also cm/s)

ABSTRACT

1. In my formula $G = \frac{Mmc}{r^2}$, the $\frac{c}{r^2}$ gives the energy of transmission of the gravitational impulse between the masses **M** and **m** — it is the velocity "**c**" that puts the energy value of the Einstein field into Newton's inverse square law. That is to say the velocity "**c**" is already involved in the Newtonian gravitational potential, but this potential (as Einstein puts it) is only one half of the total potential.

Consider a body situated at the surface of a mass. The radius of the gravitational field (**r**) will coincide with the radius (**r**) of the volume of the given mass. The energy value of the field will be exactly equal to the Newtonian potential at the surface of the mass — a geometrical principle is involved — the Newtonian potential at the surface is doubled. This is the situation in the test of general relativity for the bending of a ray of light passing the limb of the sun, also in the test for the gravitational red-shift of a ray of light issuing from a massive body like the sun or the Companion of Sirius.

The radius of the gravitational field can never be less than the given radius of the volume of the attracting mass, furthermore in this situation the energy contribution of the field, which starts at the centre of the attracting mass, will be at its highest possible level.

Since in my formula, c/r^2 represents the energy of the field, we can readily see that the contribution of the factor "**c**" (3×10^{10} cms) will be greatest in these cases, that is where the radius of the field (**r**) coincides with the radius (**r**) of the attracting mass. So my formula coincides with Einstein's famous doubling principle and gives the identical results in the above cited two tests.

The doubling principle may be understood by analogy of the structure of the gravitational field with the electro-magnetic field as consisting of TWO wave trains — INERTIA and GRAVITATION crossing each other orthogonally.

The FIELD (4 terms) preserves the REIMANNIAN indices. The DOUBLING arises from the SYMMETRY of the FIELD.

This structure of the universe is shown in my chart "VITAL CORRELATIONS" (Bayonne, N. J., 1946). This interpretation is also supported by Einstein's "equivalence principle".

Starting from this fundamental result, we can be guided by the ratio r'/r for all cases where the distance between the two bodies is greater than the radius of the volume of the given attracting mass.

And we draw the conclusion that the energy value of the factor "**c**" (as indeed the Newtonian attraction also) will decline relative to the maximum possible value (at the surface of the attracting mass) as r' becomes greater than r .

2. Applying the above findings to the problem of the excess motion of the perihelion of Mercury, we have:

Radius of the sun = 432500 miles. Mean distance of Mercury from the sun = 36 million miles.

Ratio — 1/83.

Ratio for mean distance to surface of sun = 1/82.

But in order to include the rotation of the ELLIPSE of Mercury around the sun we must double the energy contribution of the field — which is to say the additional

The above is an abstract of **A NEW ROAD TO RELATIVITY** (7 pp.) which can be obtained gratis (loose-leaf) by sending minimum postage for sea or air mail to the author and publisher: **M. R. SPIVACK**, poste restante 12, Upsala, Sweden. Bound copies (limited) £4

contribution of the velocity factor "**c**" (as energy of the field) will be 1/41 of the Newtonian potential at the surface of the sun, or 1/41 **c** (equivalence principle) (see above).

$1/41 \times 3 \times 10^{10}$ (velocity of light in centimeters per second, in the cgs system) = 7.317×10^8 .

According to Newcomb, in the American Ephemeris, the perihelion of MERCURY has a motion not accounted for by NEWTON which can be found by multiplying the MEAN MOTION by 8.06×10^{-8} .

The MEAN MOTION of Mercury appears (rounded out) as $5\ 381\ 016'' \times 100$ per century. Multiplying this figure by 8.06×10^{-8} gives $43.37''$ of arc excess motion of the perihelion per century.

As above, I derive the factor 7.317×10^8 directly as inversion from the velocity of light as multiplier of mass in Newton's inverse square law.

$7.317 \times 10^8 \times 5\ 381\ 016'' = 39.38''$ of arc (per century), which leads to a value of $42.96''$ for the total excess motion.

$3.7317 \times 10^8 \times$ mean motion, includes within the terms only 1/2 of that part of the excess motion which is due to increase of mass (with increase of velocity) of Mercury as it moves thru the perihelion.

The other half is due to increase in energy of the field, with velocity (equivalence principle). Put in other words, mass increase due to velocity increase must be added to the **Mm** in $G = Mmc/r^2$ both for the inertial and gravitational fields.

Now the Newtonian line-element ds^2 is related by the special law of relativity to the ratio v^2/c^2 in such a way that increase in the velocity **v** may, in the case of Mercury, lead to mass increase by a factor of as much as $1/2\ v^2/c^2$.

The unamended Newtonian line-element, however, can only give values equal to 1/2 of the combined effect of the inertial field and the gravitational field — and consequently only 1/3 of the non-periodic advance of the perihelion of a planet, and as we lack only 1/2 of the mass increase — a factor of $1/4\ v^2/c^2$ — this amounts to 1/12 of the total excess motion of the perihelion. To make up 1/12, we add 1/11 to $39.38 = 42.96$ seconds of arc per century. This is within the modern observed value $43.10 \pm .44$ seconds of arc per century.

In terms of **c**, we have $1/37.585$ of **c** instead of $1/41\ c$, or $1/37.585 \times 3 \times 10^{10}$ cm/s instead of $1/41 \times 3 \times 10^{10}$.

* The doubling of the value of **Mm** in Mmc/r^2 is actually a result of the transinteraction of the inertial and gravitational fields. Therefore **c** must be expressed as a multiple in the formula even if the result of the transinteraction is additive. A notation in the form $Mm + c$ (each side taken as unity) would fail to express the dynamics of the transinteraction.

In the extraction of the excess motion of the perihelion of Mercury from the mean observed motion, the velocity of light is used in centimeters per second as a multiple (inverted to deal with the line-element).

The line-element $3ds^2$ used in this section is dependent on **c** = 2 in the numerator of the formula.

Thus both forms **c** = 2 and **c** = 3×10^{10} cm/s are used as required, and are actually interdependent.

This proves that the value **c** = 2 truly derives from and represents the velocity of light.

$G = Mmc/r^2$ IS THE NEW ROAD TO RELATIVITY.

(For MARS my formula gives circa 1.3 seconds of arc per century, excess motion.)

City life

Human Settlements: The Environmental Challenge. (A Compendium of United Nations Papers Prepared for the Stockholm Conference on the Human Environment, 1972.) Pp. xvi+209. (Macmillan: London and Basingstoke, March 1974.) £5.95.

Man, Materials, and Environment. National Academy of Sciences: National Academy of Engineering. Pp. xviii+236. (MIT: Cambridge, Massachusetts and London, 1973.) \$3.95.

Topophilia: A Study of Environmental Perception, Attitudes and Values. By Yi-Fu Tuan. Pp. x+260. (Prentice-Hall: Englewood Cliffs, New Jersey, January 1974.) \$8.95 cloth; \$4.95 paper.

THE United Nations Conference on the Human Environment held in Stockholm 1972 may well prove one of the most significant events of the decade. Consequently a volume of collected papers from the conference is likely to form a valuable reference to any research group working in this area. One feature of economic growth has been the enormously rapid development of cities, particularly in developing countries, and the fifteen background papers prepared on this issue around the theme "The Planning and Management of Human Settlements for Environmental Quality" are brought together in this work. The papers are not intended to be original. What they attempt to provide is a thorough and coordinated review and analysis of current problems in each subject area. Included are general commentaries on comprehensive development planning, population growth and distribution, rural development, a case study on the environmental impact of Polish industry on Warsaw central city, transport and communication, waste disposal and sewage and lastly, a relatively short account of social, cultural and aesthetic factors. An appendix lists those recommendations of the conference concerned with settlement and urbanisation.

The main purpose of *Human Settlements* is to demonstrate the importance of the careful planning and management of human settlements and that this should be recognised as a major means of assuring an appropriate environment for human survival and development. The book emphasises the point that pollution need be by no means an unavoidable consequence of economic development. The suggestions made in the various chapters (written by different authors although not individually named here) are wide ranging but suffer in that they tend to be over-generalised and lack a certain coherence of view; possibly inevitable in a set of collected papers. Nevertheless, the work contains much of

interest to those who would argue that it is in towns and cities, where most people spend the bulk of their lives, that the environment matters most. Two factors mitigate against wholeheartedly recommending it as a purchase for the individual researcher; the first is that two years have elapsed since the conference in June 1972; the second is an exceedingly high price for what, after all, is a summary.

By comparison, *Man, Materials and Environment*, a report on materials policy in the United States in relation to environment, has been produced with laudible rapidity. Using the formula of direct replication of authors' typescript has kept the cost down to a reasonable level and resulted in a book sturdy enough to withstand its presumably limited life (in this rapidly developing research area). The book represents the findings of a number of authoritative study groups contracted by the National Academy of Sciences, one of whose roles was to evaluate the effects on US materials policy of the suggestions of the Stockholm Conference. The aim of the study groups was to identify major issues and propose some positive actions with respect to public policy and research. The detailed findings of the teams are conveniently summarised in the first chapter. The second chapter, on the economic implications of seeking a high environmental quality, sets out the arguments for and against reduction in the overall rate of economic growth. The problems of metallic and non-metallic mineral extraction, fuels and forest products and the relations of domestic policy for international trade are tackled in turn and included for good measure is a comparative case study of environmental resource problems and policies in Japan. Particular attention is paid to the operation of the 'polluter pays' principle in a mixed economy and this method is advocated for the United States (and has now also been accepted by the European Commission for inclusion into the Community Environment Protection Programme). Emission taxes rather than subsidies are reckoned to be the socially least expensive but in a number of areas, such as packaging, the suggestion is that experimentation will lead to the best allocation of charges. In the main, this volume is entirely constructive, suggesting lines of research and policy methods to safeguard the future of the natural environment. One may jibe at some of the emphases but in doing so must accept that the research proposed will help to clarify these areas of uncertainty. A book certainly to be recommended to any serious researcher in this field.

Finally, Tuan's book *Topophilia*, easily compensates for the absence of

discussion about cultural aspects of the environment found in the other volumes. Topophilia is the affective bond between people and place. In this enjoyable and stimulating book Tuan sets himself the task of describing a complicated synthesis and he has succeeded admirably. The book has Tuan's distinctive style and communicates well both his subject and his own love of it. He approaches the questions: What are our views on the physical environment, natural and man made? How do we perceive, structure and evaluate it? What have been and what are our environmental ideals? How do economy, life style, and the physical setting affect environmental attitudes and values? What are the links between environment and world views? He traces and compares the answers to these questions from the early Greeks to the modern American city, the Aivilik Eskimo and the Hopi Indian, between humans and animals. By contrasting the perceptions and activities of man, the city dweller with that of his forbears, Tuan exposes both the richness and the poverty of city life. He builds an image of 'civilised' man's perception of nature, especially the 'countryside', as a reaction to the city which itself was originally evolved as an escape from the dangers of the wilderness. Thus, Tuan describes the city as a symbol, even tracing the history and function of city nicknames. For example, of the four American cities with the largest number of nicknames, New York (the Big Apple, the Babylonian Bedlam) boasts its world status, Washington its political supremacy, Chicago projects civility and San Francisco elegance. Of a different

Dispensing gases

Lavoisier's gasometer, taken from his *Traité élémentaire de Chimie*. The gasometer supplied a stream of gas flowing at a steady rate to a reaction chamber and was used in the demonstration of the quantitative composition of water; it was introduced to Holland by Martinus Van Marum. From *Martinus Van Marum: Life and Work*; vol. 4, Van Marum's Scientific Instruments in Teyler's Museum. By G. L'E. Turner and T. H. Leveres (Noordhoff: Leyden, 1973, Dfl. 60).

culture, Tuan describes how the rain-forest environment of the pygmy with its lack of horizon and landmarks, without pattern, has resulted in a world view in which the sense of distance and perspective is "distorted" and a sense of time is curtailed.

But to dip into the book, despite the inherent interest of every page, is not to do it justice because it must be emphasised that Tuan has composed a coherent and systematic thesis, analysing those innate aspects of our values and perceptions which we seem to share with other life forms, from those which mark us as individuals, or as members of a certain culture or subgroup. Possibly, and this might be taken as an anticipation rather than an omission from an otherwise comprehensive work, Yi-Fu Tuan's thesis could have led into a deeper discussion of the evolving nature and complexity of contemporary society in relation to concepts such as "post-industrial society" and "future shock", but perhaps this is for another volume. What he has achieved is to extend a way of looking at the natural and physical environment which demonstrates and calls for an appreciation of our own and other people's values and way of life at all levels of planning. The book is inexpensive and well indexed and should provide a useful and thought provoking basic text for both the casual reader and university courses dealing with urban geography, man in relation to the environment or the humanities.

H. S. D. COLE

Acoustic orientation

Echolocation in Animals. By E. S. Airapet'yants and A. I. Konstantinov. (Translated from Russian.) Pp. vi+309. (Academy of Sciences of the U.S.S.R. Joint Scientific Council on Physiology of Man and Animals.) (Israel Program of Scientific Translations: Jerusalem; Wiley: Chichester; January 1974.) £10.50.

THIS book was first published in the Soviet Union in 1970. It reviews Russian literature up to 1969 and Western literature up to 1968 so that many important discoveries made within the past five years are not covered. The major part of the book is devoted to studies on bats. This includes sections on the biology of bats, the nature of sound waves and methods of studying bat sounds. The signals emitted by bats are described and methods of sound production and radiation are discussed. Studies on both the auditory system of bats and their echo location ability are dealt with in some detail. Echo location in birds and small mammals is also discussed, but very briefly. The chapters on Cetacea include descriptions of their biology, mechanisms

of sound production and reception, a review of the different signals emitted by these animals and a consideration of their echo location performance. The final chapter of the book is devoted to echo location in pinnipeds.

The main value of the book is that it draws together much recent Russian literature on echo location. Russian work is described in some detail, particularly in the sections on hearing in bats and on the echo location abilities of both bats and dolphins. Although this is useful for non-Russian readers, it often results in considerable imbalance in the treatment of different topics; a more comprehensive treatment of some topics would have been useful. For example, the authors describe their own equipment to illustrate methods of studying bat signals. But this excludes a consideration of equipment used by other workers, such as portable bat detectors and sound spectrographs, both of which are important in the study of bat signals. Displays from the latter, taken from the literature, are presented later in the book with no explanation and occasionally without adequate labelling.

The authors express the hope that the book will appeal to readers of many professions, but very little help is given to interdisciplinary readers or to newcomers to the subject. For instance the theoretical considerations of various aspects of echo location are often difficult to follow and many of the equations are given without any hint of derivation or a source reference. Also, descriptions of the anatomy of the larynx and the auditory pathways are given as a string of latin names, without adequate explanations or diagrams. The absence of an index is also a great drawback and makes the book difficult to use as a reference text.

On the whole the English translation from the Russian is very readable but there is some awkwardness of expression in which the exact meaning is often not clear. Some apparently literal translations have been given, for example 'humeral girdle' and 'cathode repeater' when these could have been fairly easily replaced by their more commonly accepted equivalents, here 'pectoral girdle' and 'cathode follower' respectively.

Some points of production are irksome. The latin names of species and genera are not italicised (this is a reversal from the Russian text) and the references given in the text and in the bibliography are not always accurate or consistent.

Because the literature on echo location is expanding so rapidly, a new comprehensive, critical review would be welcome. This book is disappointing both in the treatment of the material and in its presentation and does not

fulfil the requirements of such a review. But because of its account of Russian work, the book will be a useful, though expensive, addition to literature on bioacoustics.

GILLIAN D. SALES

Plant ecology in Africa

East African Vegetation. By E.M. Lind and M. E. S. Morrison. Pp. xvii+257. (Longman: London, April 1974.) £6.

THE appearance of this work will be hailed by those interested in tropical Africa as an ecological milestone, for in spite of excellent herbaria and taxonomic works, biologists have had to work in these regions without the aid of a general description of the vegetation. Indeed in many cases, large mammal research schemes have been devised without reference to botanical studies.

The authors have avoided the difficulties of describing vegetation with long lists of plant names by referring to dominant species and community structure, and relating this information to details of microclimate, water relations, soils and productivity. Additionally, they have succeeded in relating botanical information to simple descriptions of animal communities.

Vegetation types are dealt with in considerable detail and include forest habitats, rangelands (grassland and wooded grassland), inland aquatic vegetation, coastal vegetation (including intertidal and mangrove swamps), and high altitude vegetation. Considering the difficulties of describing local conditions existing at altitudes ranging from sea level to 19,000 foot, the authors have achieved a good balance between purely descriptive material and broader ecological information.

Part two discusses the influence of water availability and temperature on plant form, structure and growth followed by a short chapter on soils: the description of catenary soil associations and their vegetation types is particularly valuable.

Alan Hamilton contributes a useful chapter on vegetational history, in which he examines evidence derived from macro fossils, pollen analysis and plant geography. Of particular interest is the author's comparison of the apparently impoverished African forests with those of Malaysia and South America. He concludes that the flora of these areas have been depauperated at a time when the climate was very dry.

This valuable addition to the tropical literature will be of great value to research workers, teachers and students at all levels, and with luck will provide a new impetus for field botanical studies in Africa.

MALCOLM COE

3 different columns in one!

It's the new Whatman Multi-system - 3 different columns in one. How's it done? By using Whatman's unique interchangeable sealing pistons in one very durable glass column. Polypropylene pistons are fitted standard for ion exchange, celluloses and most organic solvents, polyamide mesh is available for gel filtration and PTFE for difficult organic and acid solvents. So you don't have to buy lots of separate columns - just select the appropriate sealing piston. And as end units are identical, chromatography can be ascending or descending. Multi-system is made to the high standards of precision you'd expect from Whatman and incorporates their sample input/delivery system to ensure homogenous loading. Multi-system is designed for easy use, versatility and durability. It offers high accuracy in a full range of column chromatography systems without triplication - all at a reasonable cost.

New Whatman Multi-system - the cleverest column in chromatography!

an important new title Metal-Insulator Transitions

Sir Nevill Mott, F.R.S.

*formerly Cavendish Professor of Physics,
University of Cambridge*

The author of this book first pointed out in a paper published 25 years ago that insulators could sometimes be transformed into metallic conductors by pressure or by change of composition and that the change was likely to be sudden, either many electrons being free or none. In the last ten years the "metal-insulator transition" has become a fashionable part of solid-state science. In this book, Professor Sir Nevill Mott reviews the present position from both the theoretical and experimental points of view.

H. G. J. MOSELEY The Life and Letters of an English Physicist, 1887-1915

J. L. HEILBRON

H. G. J. Moseley (1887-1915), the son and grandson of distinguished English scientists, a favorite student of Rutherford's and a colleague of Bohr's, completed researches of capital importance for atomic physics just before the outbreak of World War I. He was urged to devote himself to scientific war work in England, but his duty as he saw it was to join the battle. He procured himself command of a signal section in the Royal Engineers, a speedy trip to Gallipoli, and death in the bloody battle for Sari Bair.

In this work the author presents a full record of Moseley's brief and brilliant career. It gives instructive detail about Eton, which, as Mr. Heilbron shows, offered more opportunity for acquiring a foundation in science than its emphasis on Greek and games would suggest; about Oxford, a scientific backwater in Moseley's time; and about Rutherford's thriving laboratory at the University of Manchester. It describes in detail Moseley's apprenticeship in experimental physics, his growth under the tight supervision of Manchester, and his classical independent work on X rays, which almost certainly would have brought him the Nobel Prize. An epilogue sketches the chief results secured by others in the decade after his death and in the research lines he opened.

Hormones to kill insects

Insect Hormones and Bioanalogues. By K. Sláma, M. Romanuk and F. Sorm. Pp. ix+447. (Springer-Verlag, Vienna and New York, 1974.) \$45.90.

WITH its various sections written by an insect physiologist and by two organic chemists, this is primarily a chemical study of two groups of insect hormones, the juvenile hormone and the moulting hormone (ecdysone), and of the numerous synthetic materials with similar physiological activities. The natural juvenile hormone in the body of the insect they call consistently the corpus allatum hormone (CAH) and all isolated chemicals, whether natural or synthetic, which show the same activities in greater or less degree, they call 'juvenoids'. Likewise the natural moulting hormone in the body is named the prothoracic gland hormone (PGH) and all natural and synthetic chemicals with the same activities they call 'ecdysoids'. This is a useful convention which avoids much unnecessary argument.

The chemical structure and the various syntheses devised for natural juvenoids and ecdysoids are described in great detail with clear and consistent structural formulae throughout, and at the end of the book a table of some 350 compounds gives structural formulae and the approximate dosage required for equivalent activities of each, in a range of a dozen or so insects which have been extensively used for assay purposes; and a further table gives an alphabetical list of the same 'juvenoids' according to their chemical derivation. Sorm and Romanuk have worked extensively in this field of organic chemistry in relation to both juvenoids and ecdysoids, and the book contains much previously unpublished information from their laboratory. But published work from elsewhere is well covered; although doubtless much more information remains in the hands of commercial firms which have been active in this field.

The table of activities provides a useful basis for reflections and speculations about the chemical factors concerned in the relative activity of juvenoids—but the figures must, of course, be interpreted with caution, since a 15-fold increase in activity of a given compound may result if it is applied to the cuticle at a dilution of 1:1,000 or more in a non-volatile oil, as compared with the usual method of application in a volatile solvent (such as acetone or octane) which leaves an undiluted residue of the active principle on the surface. And a similar increase in activity results if the application is spread in the form of small doses throughout the sensitive period in the

life of the insect, as compared with a single application at the outset.

The authors are principally concerned with the possibility of juvenoids (and to a less extent of ecdysoids) being used as insecticides: to render insects non-viable by disturbance of their normal metamorphosis; to arouse dormant insects from diapause at some inclement season of the year; to sterilise females by adverse effects on their developing ovaries; or to produce non-viable embryos or teratological injuries to young larvae by applications to pregnant females or to newly laid eggs. As a background for such considerations Sláma provides a very full review of the normal hormonal physiology of insects and of the effects of ecdysoids and juvenoids.

The endocrinology of insects is beset with numerous pseudo-problems. What are the chemical effects of ecdysoids? Do they induce DNA synthesis, or RNA synthesis? When renewed growth results in cell multiplication (as it commonly does) DNA synthesis of course occurs; but if sufficient cells already exist it has long been known that moulting (with or without metamorphic change) can take place without DNA synthesis. Renewed growth commonly means renewed protein synthesis; it has long been known that within an hour or so of ecdysoid treatment RNA is increasing in the affected cells—but the same happens in many other cells without the need of ecdysoids. An early effect of ecdysoids at metamorphosis in some caterpillars is conversion of tryptophane into red ommochrome pigments; in fly larvae, the conversion of tyrosine into quinones to sclerotise the puparium. But all such effects are episodes in the growth process which ecdysoids initiate; they are not direct effects of the hormone. The juvenile hormone was originally described as 'inhibiting' metamorphosis; and that is a fair enough description. Unfortunately this was interpreted to mean an antagonistic relation between this hormone and the moulting hormone; an idea which has led to much unprofitable controversy. The earliest suggestion on the nature of the 'inhibitory action' of the juvenile hormone was that it accelerated the deposition of the new cuticle and thus arrested 'differentiation toward the adult form'. This process was clearly demonstrable; but many years elapsed before it was realised that it is due to excessive amounts or precocious timing of moulting hormone supply and not to the juvenile hormone. Finally, it is often very difficult to distinguish between direct effects of a hormone and feedback or homeostatic effects resulting from its action elsewhere in the body. By and large Sláma adopts the rational view, in dealing with these

problems; but he gives a conscientious account of much of the literature, which tends to obscure the rationality of his approach.

V. B. WIGGLESWORTH

Liquid physics

Liquid State Physics: A Statistical Mechanical Introduction. By Clive A. Croxton. Pp. x+421. (Cambridge University: London, May 1974.) £10.

DR CROXTON'S intention in writing this book was to provide a guide to the uninitiated. On the whole, I think he has achieved this aim, although the book is not in any sense an elementary one. The material covered in the first chapter deals with the theory of imperfect gases and forms a sound basis for the latter sections. The method of correlation functions is introduced in the second chapter and is applied to the problems of the liquid state in the way associated with the names of Kirkwood, Rice, Percus and others. Chapters 3 and 5 aim to discuss the numerical side of the subject and to make a comparison between theory on the one hand and experiment or computer simulation on the other. Here the difficulty that faces all authors in writing textbooks on subjects which are developing rather rapidly is that some of the material necessarily is out of date even before the book is published. There are statements which doubtless Dr Croxton would now wish to modify in the light of recent work.

Chapter four is, to my mind, the most worthwhile in the book. The nature of the surface of liquids has been sadly neglected in the past both from an experimental and a theoretical point of view. Dr Croxton brings the special properties of the surface into the context of distribution functions and contact is made between theory and measurement by special reference to the surface tension. This is a field in which the author himself has made a major contribution and this fact is reflected in the clarity with which difficult ideas are explained. The chapter concludes with a short but very useful exposition of the way that the basic theory must be modified to handle surface properties of quantum liquids.

The final chapter is concerned with transport processes, and this is a subject which has been covered quite adequately in the past in a number of review articles. There is perhaps room for a little more comparison between the neutron diffraction work and theory, but this is compensated by the very comprehensive list of up-to-date references which the author attaches to the chapter.

J. E. ENDERBY

Weapons and laws of war

The Problem of Chemical and Biological Warfare, Vol 2: CB Weapons Today; vol. 3: CBW and the Law of War. Stockholm International Peace Research Institute. Vol 2: Pp. 420; vol. 3: pp. 194. (A study of the Historical, Technical, Military, Legal and Political Aspects of CBW, and Possible Disarmament Measures.) (Almqvist and Wiksell: Stockholm; Humanities: New York; Elek: London, 1973.) Vol. 2: Sw.kr.75; \$16.50; £7.50; vol. 3: Sw.kr. 40; \$10; £5.

THESE two latest volumes in the SIPRI series maintain the scholarly distinction and absorbing interest of their predecessors (volumes 1, 4 and 5, published in 1971, were reviewed in *Nature*, 236, 355; 1972.) Volume 2 now takes the historical survey of CB Weapons, defences, policies and programmes beyond 1945 where volume 1 left off. It brings together in a masterly way the available information on contemporary CBW technology and examines as far as is known the policies of each state towards the use of CBW, including tables indicating continent by continent states' formal attitude towards the 1925 Geneva Protocol and the 1972 Convention on Biological and Toxin Weapons, which is not yet in force.

This volume, written by Julian Perry Robinson, with the assistance of Carl-Göran Hedén and Hans von Schreeb, is essentially a work of information, endowed with more than 1,600 references in addition to footnotes. Special attention is paid, as one would expect in a SIPRI publication, to the importance of research and development programmes and the relationships thus engendered between the military and scientific communities (pages 325-332). Specific R and D programmes, such as that concerned with 'binaries', are also described.

Volume 3, written by the Danish peace researcher Anders Boserup, addresses itself to the question: what does international law, and specifically the international law of war, have to say about CBW? One might think this a straightforward question, the answer to which could scarcely deserve a volume to itself: a question in any case less interesting than whether the law is 'strong' enough, and if not what can be done to strengthen it, subjects on which SIPRI had already had much to say in volume 5. One might therefore expect volume 3, being "only concerned with the legal issues in the narrow positivist sense of determining what the law says" (page 42), to be uncontroversial to the point of boredom.

Not so. For there happens to be considerable disagreement over the state of the law. Most of the responsibility for the present uncertainty must

be laid at the door of those governments which have made it their business to discover and exploit supposed ambiguities in the Versailles Treaty formula for defining chemical weapons. This 1919 formula—"asphyxiating, poisonous or other gases and all analogous liquids, materials or devices"—was also embodied in the Washington Treaty of 1922, which did not enter into force, and the Geneva Protocol of 1925, which did. More than 90 states are now parties to the protocol.

What is agreed is that there exists a legal prohibition on the use of chemical weapons and biological methods of warfare. But is the chemical ban as absolute as the biological? Is the content of the prohibition in customary international law more extensive than the treaty prohibition binding only parties to the Geneva Protocol? Is retaliatory use of CBW as firmly banned as first use? And what is the legal effect of the reservations made by many states, including Britain, upon ratifying the protocol, reserving the right to employ CBW against not only the state which violates the protocol but equally against that state's allies?

The SIPRI study examines these and other questions but deals most fully with two matters of bitter controversy: harassing agents (gases such as CN and CS) and chemical herbicides. The controversy is first resolved, systematically, into four questions: (1) Is the use in war of harassing agents prohibited, on condition of reciprocity, among parties to the Geneva Protocol? (2) Is the use in war of herbicides likewise prohibited under the protocol? (3) Is the use in war of harassing agents prohibited nowadays by a peremptory norm (*jus cogens*) of customary international law, binding (by definition) on all states irrespective of their attitude to the protocol? (4) Is the use in war of herbicides likewise prohibited by a peremptory norm?

SIPRI's treatment of these four key questions is thorough, well informed and tightly argued. In the end we find that the answer given to each of the four is yes, although it is admitted (pages 137-8) that (4), the customary prohibition of herbicides, is less conclusively proved than the first three. This is partly because *jus cogens* is a vague concept, with no such precise apparatus of proof as the rules of treaty interpretation provide; partly because evidence of state practice and belief is relatively slender.

So SIPRI settles for the most extensive view of the state of the law, incidentally supporting U Thant and the United Nations General Assembly in the views which they separately expressed in 1969 and from which few states other than the United States

have ever deviated. Some of the restrictive interpretations suggested seem to have been based on misunderstandings or ignorance of international law, whereas of others the kindest thing that can be said is that they "can only arise from a highly specious reading of the Protocol" (page 43). Both comments apply in full measure to the notorious British policy statement purporting to exclude CS gas from the scope of the protocol: a policy as legally untenable (and unnecessary) now as when it was first announced in 1970. SIPRI once again condemns the British statement (pages 59-62) but, as in previous volumes of this study, attributes it to improbable causes, overlooking the clues contained in its very ineptitude of expression.

In conclusion this volume can be warmly commended, but with two qualifications. Its author did not have time to take adequate account of the implications of states' signature and ratification of the 1972 convention. Indeed, the reference (page 149) to this partial disarmament treaty is marred by a faulty argument regarding the significance of the withdrawal clause which assumes, mistakenly, that use of BW and toxins was among the activities banned by the convention. (It should have been; but on that point Britain was obliged, by Sweden and the East European states, to give way in the autumn 1971 round of negotiations, so that the Convention ended up with no ban on use as such). Less excusable on grounds of time is the failure (pages 62-3) to distinguish between interpretations of the Geneva Protocol and statements of intent for future CW agreements. The 1970-71 policy declarations of Canada, Norway and the Netherlands were clearly of the second type and should not have been adduced as evidence supporting the extensive interpretation of the protocol.

N. A. SIMS

Geochemistry handbook

Handbook of Geochemistry Vol. 2/3. K. H. Wedepohl (executive editor) and C. W. Correns, D. M. Shaw, K. K. Turekian and J. Zemann (editorial board). Pp. iv+845. (Springer-Verlag: Berlin and New York, 1974.) DM 258; \$99.40.

THE *Handbook of Geochemistry* has been taken a further substantial step towards completion with the publication of this section. Chapters for sixteen new elements are introduced; of these only that for barium is supplied in entirety, although substantial parts of the chapters on nitrogen, fluorine, gallium, selenium, indium, tellurium and thallium are also provided. Eleven

other sections relate to incomplete chapters which have already been published and these allow the completion of another nine chapters (lithium, sodium, potassium, zinc, rubidium, cadmium, cesium, platinum and bismuth). Now that more than half the text, in both number of elements and pages, is complete (chapters for more than fifty elements are now complete, or virtually so), much of the frustration caused by gaps is removed. The standard of production remains high.

D. G. MURCHISON

Putting viruses together

Morphogenesis of T-Even Bacteriophages. By B. F. Poglazov. Pp. vi+105. Monographs in Developmental Biology, Vol. 7. (Karger: Basel, London and New York, 1973.) 54 Sw.fr.; £7.85; \$16.75.

In a monograph which might better be entitled "T4 structural proteins and their assembly", the author has attempted to integrate the extensive physical and chemical studies on the proteins of bacteriophage T2 from his laboratory with the genetic analysis of phage development which has come out of laboratories in Europe and the United States in the past ten years. The product is a review of the results of roughly 100 papers arranged according to the part of the phage structure whose assembly is being considered.

Of the seven chapters, the two principal ones are devoted to assembly of the head and tail of T4 and T2. The discussion of head morphogenesis is devoted to the inferences on form determination which can be drawn from genetic analyses of mutants in T4 head genes and the interesting experiments from Poglazov's own laboratory on structure formation from solubilised phage T2 head protein. Unfortunately, little mention is made of the work which has been published to elucidate the role of DNA in phage head formation, a subject of considerable recent controversy.

The assembly of the phage tail receives the longest treatment—fully half the book. Again most space is devoted to the work of Poglazov and his collaborators on dissociation and reassociation of tail tube and sheath protein.

A short and extremely dense chapter is devoted to tail fibre assembly. The brevity is unfortunate because the fibre assembly pathway is certainly the best example of a morphogenetic pathway in T4 assembly, and beautifully illustrates the complementary approaches of genetics, immunology, electron microscopy and biochemistry to problems of structure formation. But enough references are given to

enable the interested reader to fill in the details for himself.

In his devotion to detail, Poglazov obscures some of the larger problems of phage morphogenesis. There is hardly any mention of the timing of phage development, regulation of quantities of various components synthesised, or of possible mechanisms of length or form determination.

Generally, the author's policy is to present observations and results without comment. The lack of synthesis will make for difficult reading for the uninitiated, and the lack of evaluation of published results will at times be misleading for those not already familiar with the difficulties of experimentation in the field.

MICHAEL K. SHOWE

Weather satellites

Climatology from Satellites. By E. C. Barrett. Pp. xii+418. (London Methuen: London, May 1974.) £7.90.

THE idea of this book, if I have divined its origins aright, is to liven up the teaching of climatology in schools—and, perhaps, to geographers in universities—by introducing the subject through the medium of satellite pictures, backed up by the analysis of other kinds of satellite data. Or it may be meant just to give a fresh view of the subject in this way. The 41 satellite photographs are the book's main attraction. Among the more impressive ones are several which show the frontal cloudsheets of the northern and southern hemispheres trailing till they meet in the equatorial convergence and one (plate 19), a half-month composite, which shows the cloudless zone along the equator in the Pacific extending from the Americas as far as 170°E. It is a pity that the minimum brightness composite (plate 9) which gives a sample of the rendering of ice and snow and persistent cloud was chosen from the Antarctic summer.

The book is written for geographers; others may find it useful as a handy small guide to the early history of weather satellites, the data and issues which are now available, the symbols in common use on map analyses of satellite information and so on. Among its features are a table (on page 21) of the spatial resolution and frequency of various kinds of satellite observation, the list of routinely available average, minimum and maximum brightness maps and their uses (on pages 50-51), the long table (pages 87-92) on identification of cloud types from satellite photographs, the samples of infrared techniques for deriving surface and cloud-top temperatures, mean cloudiness and relative humidities and the

introduction (on pages 111-7) to the derivation of precipitation from satellite surveys. More could have been said about the inadequacy of precipitation measurements at the surface, with the insoluble problems of representative catchment of the precipitation at sea and of snowfall anywhere, and the potential virtue of uniformity in derivations, however difficult and indirect, from satellite observations. We learn (page 124) that most cloud bands in all latitudes are aligned with the surface wind; we learn also, however, the complications and limited possibilities of accuracy in deriving wind speeds and cloud-top heights.

But whether climatology can be taught in the way this book attempts it may be doubted. The effect is rather like that of walking into a cinema in the middle of the film: the order of presentation is strangely jumbled. We meet the gradient wind on pages 120-3, the sun as the source of energy on page 147 and are rewarded for patience with a nice set of pole-to-pole profile diagrams of the various components of the energy budget on page 159.

I hope not to be unfair in saying that I found this author's style foreign and difficult; for example the ambiguous statement on page 71 that: "the amplitudes and locations of the maxima and minima of incoming radiation are seasonally variable" (within a given season? from season to season? or when we compare the same season in different years?). The waves in the upper westerly winds are introduced (page 196) with the statement that they "undulate meridionally". The stratospheric circulation is explained (page 209), only too briefly, as "a huge standing wave related to the zone of maximum insolation": in this the book clearly attempts too much. Finally, the odd statement is made that an atlas of cloudiness might seem uninteresting except in relation to programmes of space research and Earth Resources Technology Satellites, though we are persuaded that the knowledge is needed for computer modelling and for tracing the general circulation of the atmosphere: surely the last named is the average viewer's first exciting impression of satellite cloud photography.

The author is an enthusiast for the use of satellite observations and has contributed valuable studies of the circulation and cloud development over the tropics, which occupy much of the regional climatology section of the book. Despite the irritating awkwardnesses, the book succeeds in communicating this enthusiasm and may therefore succeed also in stimulating the general reader to try out the use of this fascinating tool himself and seek further understanding. H. H. LAMB

Group theory

Classical Groups for Physicists. By Brian G. Wybourne. Pp. xvi+415. (Wiley: New York and London 1974.) £10.60.

THIS is a fine introduction to the group theoretical method in modern physics. During the past twenty-five years, the significance of symmetry transformations in describing physical phenomena has come to be recognised more and more and with it the use of group theory—and particularly the theory of Lie groups, due to the work of Wigner, Racah and others. This volume gives an exposition of Lie group theory for physicists following the traditional treatment of Weyl and Cartan as modified by the work of Dynkin and the Russian School.

The book divides into two major parts. The first presents a detailed exposition of the principal features of Lie groups and algebras and their topological structures, leading up to the Cartan–Weyl classification. Diagrammatic techniques of Dynkin are used to construct simple Lie algebras, and concepts of weights, Casimir invariants, and Clebsch–Gordon coefficients are discussed in detail. The discussion is mostly carried through for compact groups though there is a brief section on the non-compact $SU(1, 1)$. This portion of the book is written very much from a physicist's point of view—that is to say, principal concepts are introduced, results stated though not always proved with the emphasis being very much on ideas and the methodology rather than on rigour. I thoroughly approve of the approach—I only wish this part of the book was longer.

The second part treats the group theory of three topics in detail—the isotropic harmonic oscillator, the hydrogen atom and the shell structure in nuclear theory. There is an excellent bibliography.

I would recommend the book for postgraduate students in nuclear theory and high energy physics as a self-contained introduction to the advanced ideas and techniques.

ABDUS SALAM

Intelligent beings

The Development of Mind. By A. J. P. Kenny, H. C. Longuet-Higgins, J. R. Lucas and C. D. Waddington. Pp. 152. (Gifford Lectures 1972/1973.) (Edinburgh University: Edinburgh, April 1974.) £2.25.

THE traditional Gifford Lecture, with some notable person putting forward a synthesis of his views on natural theology, is a well established part of the British intellectual scene. For two recent winters, however, something

different has been tried: a group of four people have shared the lectures, and at each session one person gave an opening statement, and there was then discussion between the four. Although each man is widely talented, they could be labelled as specialists in artificial intelligence, philosophy, theology, and biology respectively: and this volume reports the second series of such lectures.

On the whole, the title is taken as referring to the appearance of minds in the course of evolution: not in the other possible sense of the development of a mind from that of the baby to that of the Gifford Lecturer. There are some cursory references to the latter problem, but on the whole the assumption is taken that "there is overwhelming evidence that our most primitive skills . . . are inborn". The discussion concentrates mostly therefore on the view of the world we ought to have if evolution has given rise to creatures possessing our capacities: problems in fact not too dissimilar from those handled by Monod in *Chance and Necessity*, and that book is mentioned several times. By contrast with a book like Monod's, one naturally does not get a unified and single point of view in all its complexity: the main merit of this kind of attack is rather that any overemphasis by one lecturer can instantly be picked up by another. Thus for example the argument that language is difficult to explain by natural selection, because it is only of benefit when more than one person has it, is immediately countered by the argument that we only have to explain a series of small steps in improving communication, rather than the sudden appearance of a complete complex syntax. For those who want the balance and interaction of the various points of view represented, this will in some ways be a more satisfying book than that of Monod. Probably one should not lay down that all future Gifford Lectures should be of this type: but it was worth the attempt on this occasion.

Reaction to lectures on natural theology is bound to be a personal matter: but in two ways this volume fails to speak to my condition. First, the emphasis is on the processes which produce mind and not upon its nature, and this is linked with a silent assumption that all human beings have the kind of minds which can be heard discussing in Oxford and Edinburgh common rooms. Yet the outburst of studies of the behaviour of the developing child, and for that matter of adults with a rather different type of mind from the academic one, make one a bit doubtful of the generality of this kind of discussion. Our ancestors looked at the species which now exist

and could see no way to explain them other than by special creation: and there is something of the same flavour about these discussions which take the mind as an unanalysed given, without considering development within the individual. To psychologists therefore, whose professional blinkers forbid them to take for granted what the mind is and what it does, this kind of discussion is bound to seem curiously old-fashioned and irrelevant.

This kind of reaction leads on to another at a more human level. The pressing problems of natural theology seem to some psychologists to lie, not in the origin of species including ourselves, but in the problems which a human being may face in achieving a stable and satisfactory way of organising his mind, in the existence of alternative ways of doing so, in the need to change from one way to another as circumstances change, and in the difficulties in doing so once some mode of reaction has been established in an earlier situation. In the older, and doubtless outworn, language, these are the problems of the consciousness of sin and the experience of redemption, rather than those of the creation of the world, and perhaps they might be regarded as outside the field of the Gifford Lectures. They can, however, be the subject of rational discussion, quite apart from the particular solutions offered to them, and some of us would like to read a similar volume on that line even more than this one.

DONALD E. BROADBENT

Where sediments build up

Depositional Sedimentary Environments, with Reference to Terrigenous Clastics. By H. E. Reineck and I. B. Singh. Pp. xvi+439. (Springer-Verlag: Berlin and New York, 1973.) DM108; \$44.30.

IN recent years there has been a spate of books published in the field of sedimentary geology. These have included general texts on the origin and petrography of sedimentary rocks and processes of sedimentation, and many dealing with specific sedimentary environments. The authors of this volume are to be congratulated on compiling and analysing all the major modern sedimentary environments in which terrigenous clastic sediments are deposited. The potential scope of the subject is so vast, yet the authors have succeeded in summarising it in a most readable manner. To this end, most of the information can otherwise only be seen in journals, so the book should provide both professional geologists and students with a commendable review of depositional environments.

The first part of the book deals

Second skin

Sloughing palmate gecko from the Nambi desert in south-west Africa. From *The World of Reptiles and Amphibians* by Maurice Burton, (Orbis: London, February 1974.) £2.50.

specifically with primary sedimentary structures and textures, commencing with a brief summary of the major hydrodynamic factors controlling the formation of certain types of structure. This section is similar in its approach to other monographs on the subject. One of its assets is that, as well as being descriptive, the authors have attempted to summarise the varied opinions on the genesis of sedimentary structures. It is perhaps unfortunate that more attention was not paid to the hydrodynamic significance of sedimentary structures, and that the importance of chemical and mineralogical parameters should have been restricted to just over two pages. Also, this section does get involved at times with rather laborious classification schemes.

In the second and most important part of the book the emphasis is placed on modern environments and includes an encyclopaedic treatment of glacial, desert, lake, fluvial, delatic, coastal, shelf and lagoon, tidal flat and ocean basin environments. The authors have, where possible, based their discussions on studies published within the last decade. Consequently, the book provides an up to date, and at times stimulating, appraisal of the subject. Certain topics have been treated to greater depths than others, due in part to a combination of the particular expertise of the authors and a current lack of detailed knowledge on some modern environments. But, in all chapters, the writers have been objective in their efforts to present the processes and characteristic structures and sequences typifying given sedimentological regimes. A pleasing feature is that, from the choice of examples, it is clearly demonstrated that more than one facies model is often required for a particular environment. Furthermore, the importance and application of biological parameters is stressed throughout.

The book is lavishly illustrated with

579 diagrams and photographs, mostly of high quality, but often rather repetitive. It is in fact a little irritating at times to find, due to their large number, that many of the figures are out of phase by several pages with the text. Editorial standards are high, and both printers' and geological errors are at a minimum. The reference list is most comprehensive and should prove to be invaluable for literature searches.

BRIAN WAUGH

Stellar surface

Cosmic Gas Dynamics. By Evry Schatzman and Ludwig Bierman. Pp. xv+291. (Wiley: Chichester, March 1974.) £8.40.

PROBLEMS of gas dynamics are of importance in most branches of theoretical astrophysics, and a comprehensive treatise on cosmic gas dynamics would be vast indeed. A glance at this volume immediately indicates its specialised nature in spite of its general title. Roughly two thirds of the book is taken up by Schatzman's article on stellar hydrodynamics. The remainder is devoted to a study of the physics and dynamics of the solar wind written by Biermann. There is no attempt to link the two articles and they can be read independently of one another.

Schatzman's article is concerned largely with hydrodynamic and hydro-magnetic phenomena occurring in the outer layers of main sequence stars. Stars of spectral types A to G possess extensive outer zones in which the energy transport is largely by convection. The properties of convection zones are not well understood, and their structure is generally described by the phenomenological approach of mixing length theory. The convective motions act as a source of pressure waves which may propagate outwards into the surrounding radiative zone. The study of these waves and their effects are of great

importance in establishing the properties of the stellar corona. A large section of the article deals with these problems. Various aspects of stellar surface activity, such as solar flares, are discussed and the article ends with a brief discussion of the possible role of stellar mass loss in the angular momentum decrease which must occur as stars contract onto the main sequence. Although well written, the article makes few concessions to the reader, and a fairly good background of hydrodynamics and magnetohydrodynamics is necessary to follow the discussion.

The existence of the solar wind is a direct consequence of the types of subsurface stellar phenomena referred to earlier. Biermann first briefly reviews the properties of the solar corona, and then describes in more detail the gross dynamics of the corona and solar wind. A logical progress from simple inviscid hydrodynamics to two-temperature models is followed. The conditions under which the flow may be described by macroscopic equations are discussed and reference is made to solar wind models in which the ion properties are approached by way of the Vlasov equation. The interplanetary magnetic field and the angular momentum of the wind are briefly treated, and the article ends with a short discussion of the interface of the wind and interstellar medium. I was rather disappointed to find no account of the interaction of the wind with planetary bodies and comets.

Both authors are well known for their extensive contributions to the work they describe and write with considerable authority. I have two criticisms. The diagrams have been taken directly from the literature without any attempt to relate their size to the amount of information contained in them. The caption arrangements are very poor. Captions are separate from the figures in some cases, two figures are captioned merely as "universally familiar", and one caption is in French. The second criticism is the very long delay between the writing of the articles and the publication date. The contents are based on lectures given by the authors in 1968 with slight amendments made in 1970. This delay has been particularly unfortunate for the otherwise excellent article by Biermann. Since the time of writing, satellite observations have given a great deal of information directly bearing on the subjects in the article. Considerable progress has been made theoretically and the extensive reviews in the *Asilomar Conference Proceedings* are available in print. The publication delay has not affected the stellar hydrodynamics section as much, but then £8.40 is a great deal to pay for 176 pages of lecture notes. J. E. DYSON

obituary

Vannevar Bush

Dr Vannevar Bush died on June 28 at his home in Belmont, Massachusetts. He was 84. He had been Professor, Vice-President and Dean of Engineering at the Massachusetts Institute of Technology in the 1920s and 1930s, and President of the Carnegie Institution in Washington, DC, from 1939 to 1955. While there, he served as science adviser to President Roosevelt. He was Chairman of the Corporation of MIT from 1957 to 1959 and Honorary Chairman from 1959 to 1966.

Bush received BSc and MSc degrees from Tufts College in 1913. With money for only one year's study, he entered MIT and earned a doctorate in electrical engineering in that single year. In 1916, the DEng was awarded to him jointly by MIT and Harvard.

After the entry of the United States into the First World War he did anti-submarine research, developing a magnetic device for detecting submarines. In 1919 he returned to MIT as associate professor of power transmission.

In studies of power lines, he found that traditional mathematical methods were inadequate for the analysis of increasingly complex systems. In 1925 he set several graduate students to work designing an analogue machine called the Product Integrator to grapple with such problems. It was the first in a series of machines which were precursors to modern computers.

His Differential Analyser was completed in 1931 and was so successful that it served as a prototype for machines built elsewhere in Europe and the United States. This led to the construction of a 100-ton giant known as the Rockefeller Differential Analyser, which had 2,000 tubes, 200 miles of wire and 150 motors.

In 1939 he began meeting with a small group to discuss what might be done to prepare for a massive technological programme which was thought to be essential if the United States entered the war. They concluded that the nation was "... pathetically unprepared from the standpoint of new weapons".

In early 1940, Dr Bush went to President Roosevelt with the group's plan for the establishment of the National Defense Research Committee. The President approved, and appointed Dr Bush as its chairman. Compton took charge of radar research, Conant chemistry and explosives, Jewett com-

Dr Bush with the differential analyser (Courtesy: MIT).

munications and Tolman armour and ordnance. Research activity became so extensive that by 1941 the Office of Scientific Research and Development was established, with Dr Bush as director.

In 1941, after preliminary studies indicated the feasibility of developing an atomic bomb, Dr Bush secured the President's approval to proceed and gave Dr Conant the responsibility for the programme. When the project was ready for large-scale construction, it was turned over to the Corps of Engineers, which established the Manhattan Engineering District to carry the enterprise to completion. A Military Policy Committee, to function as a kind of board of directors, was formed, with Bush as chairman and Conant as his deputy. Following the death of President Roosevelt, it was Dr Bush who gave the first detailed information about the bomb to President Truman. Bush, Conant and Compton were members of the Interim Committee which, after careful deliberation, recommended to the President that the bomb be used.

Of that recommendation, Dr Bush wrote in *Pieces of the Action*: "I knew that Japan would succumb within a matter of months even if the bomb were not used. But I also knew that an invasion of Japan was already being mounted, that it involved several hundred thousands of estimated casualties, and that once rolling, it could not be stopped in its tracks. I also felt that use of the bomb, far less terrible in my mind than the fire raids on Tokyo, if it brought a quick end to the war, would save more Japanese lives than it snuffed out."

"But there was another aspect of this heavy subject. By that time I knew that civilisation faced an utterly new era,

and I felt that it might as well face it squarely. I knew that nerve gases, delivered in a dozen different ways, could be as terrible as an A-bomb. And I had no illusions about the potential power of biological warfare. When science became really applied to warfare, which occurred only during the Second World War, it presented humanity with two alternatives. Either it could refrain, formally or informally, from use of weapons of mass destruction—not only the bomb but also gases and bacteria and viruses—or it could thrust itself back into the dark ages. Over twenty years have passed, and the world has understood and has thus far refrained. If for no other reason I would justify the use of the bomb at Hiroshima and Nagasaki because it was the only way in which the dilemma could be presented with adequate impact on world consciousness."

At the same time he was responding to Roosevelt's request for a comprehensive report on postwar scientific research policy. Published in 1945 under the title *Science the Endless Frontier*, it contained the recommendations of committees (which Dr Bush had organised) to make studies, with respect to health, education, unemployment and other areas in which science would play a part. Dr Bush wrote: "... without scientific progress no amount of achievement in other directions can insure our health, prosperity and security as a nation in the modern world ... Basic scientific research is scientific capital. Moreover, we cannot any longer depend upon Europe as a major source of this scientific capital."

The report was a stimulus for growth in science and technology with an impact on virtually every aspect of American life. The National Science Foundation was established as a major source of Federal support for research. The Office of Naval Research was formed to move far beyond the limits of traditional military research. When the Department of Defense was organised Dr Bush became chairman of its Research and Development Board.

A justifying typewriter was one among a number of Dr Bush's inventions. While still at MIT he invented a high speed library research machine called the rapid selector which was taken over by the Navy for cryptanalysis. He obtained his first patent in 1912 while he was still in college, for a machine mounted on two bicycle wheels which could be used in surveying land. He was granted dozens of patents and built many unpatented devices, ranging from a birdfeeder which discriminated against pigeons and bluejays to hydrofoil boats.

Endless Horizons and *Modern Arms and Free Men* were two of Dr Bush's popular books.

Classified Advertisements

CONDITIONS. All advertisements will only be accepted on the condition that the advertiser warrants that the advertisements do not in any way contravene the provisions of the Trade Descriptions Act 1968 and the Race Relations Act 1968. The Publisher also reserves the right to refuse, amend, withdraw or otherwise deal with all advertisements submitted to him at his absolute discretion and without explanation. All advertisements must comply with the British Code of Advertising Practice.

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes. Semi-displayed £3.60 per 10 mm. Minimum £7.20, each additional 2 mm 72p. Full page £230.00. Half page across £125.00. 30p is charged for the re-direction of replies to advertisements with a box number.

APPOINTMENTS VACANT**SENIOR BIOCHEMIST**

A leading British pharmaceutical research organisation has a vacancy for a Senior Biochemist with a few years post-Doctoral experience to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for an Application Form from The Secretary, Biorex Laboratories Limited, Biorex House, Canonbury Villas, London N1 2HB.

(934)

DEPARTMENT OF CYTOGENETICS
The Charles Hayward Research Building
QUEEN ELIZABETH HOSPITAL
FOR CHILDREN
HACKNEY ROAD, LONDON E2 8PS
TECHNICIANS

and

JUNIOR TECHNICIAN

required in the above department of this teaching hospital for routine diagnostic and research laboratory work concerned with the identification of human chromosome abnormalities. Specific experience not essential as training will be given. The junior technician will also be trained in histopathology. Minimum qualifications; A.I.M.L.T., H.N.C. or Degree with State Registration (for Technician post) and four 'O' Levels (for Junior post).

New Graduates qualify for State Registration after one year's service. Salary scales: Technician £1,986 to £2,961 and Junior Technician £1,071 to £1,863 p.a. (inclusive of London Weighting Allowances). Both subject to threshold agreements. Apply, by letter, to the Senior Cytogeneticist giving personal details, qualifications, experience and names of two referees.

(933)

RESEARCH ASSISTANT

(GRADUATE OR TECHNICIAN)

to work on Endocrine and Reproductive problems in Laboratory mammals. Experience in small animal operative techniques an advantage. Basic salary £1,557 to £2,451 p.a. Application with full details to Professor R. V. Brooks, St. Thomas's Hospital Medical School, London SE1 7EH.

(936)

If your immediate and indefinitely distant genetic survival matters to you please write to Box No. 938 Nature.

(938)

BIOCHEMIST or CELL BIOLOGIST, SWEDEN

Pharmacia Fine Chemicals AB, manufacturers of SephadexR and other products for biochemical separations, require a biochemist or cell biologist to work at our headquarters in Uppsala, Sweden.

The successful applicant will join our Scientific Information and Technical Services group. The activities of the group include

- ★ the preparation of all kinds of scientific information material
- ★ applications work and laboratory testing of new products
- ★ lecturing

but applicants should be prepared for extremely varied work and certain amount of travelling, mostly within Europe.

Applicants should have research experience in biochemistry or cell biology. Clear and accurate expression in the written word is essential with English as the Mother tongue.

This is an important position and carries an appropriate salary. Preferred age 25 to 30.

Write in confidence to:

Mr D. Sweetman
Pharmacia (Great Britain) Ltd
Paramount House
75 Uxbridge Road
London W5 5SS

Pharmacia
Fine Chemicals

(885)

The Editor of

Nature

is looking for a

PERSONAL ASSISTANT

This will be a very varied job involving many standard office duties such as shorthand and typing but also offering opportunities for someone with a good science background who will want to become closely associated with the business of trying to keep the journal stimulating and topical.

Write to Dr D. Davies, *Nature*,
4, Little Essex Street,
London WC2R 3LF.

POLYMER CHEMIST

RAPRA requires a Polymer Chemist for its Polymer Supply and Characterisation Centre. Duties are envisaged as providing technical supervision for a comprehensive GPC unit which utilises three GPC instruments and some research activity into the GPC method.

The situation would be especially suitable for a Post-Doctoral researcher who has an interest in developing GPC expertise.

A Company house may be available.

Apply in writing, please, to: The Personnel Officer, Rubber and Plastics Research Association of Great Britain, Shawbury, Shrewsbury SY4 4NR. (937)

MEDICAL RESEARCH COUNCIL

LABORATORY OF MOLECULAR BIOLOGY

POSTDOCTORAL ORGANIC CHEMIST or **BIOCHEMIST** required to join a group working on the partial synthesis and folding properties of proteins. Three-year appointment, salary according to age and experience. Applications, including curriculum vitae and the names of two referees to Dr R. C. Sheppard, M.R.C. Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, as soon as possible. (886)

SUNDERLAND POLYTECHNIC LECTURER I IN ECOLOGY

Applications are invited for appointment to the above post from October 1974 or January 1975. Applicants should have a good honours degree and preferably a higher degree with special interest in eco-physiology. The successful candidate will be required to undertake teaching of animal physiology and to assist in the teaching of Ecology.

Salary in accordance with Burnham Technical Scale, viz.:

Lecturer I: £1,800 to £3,045.

An application form and further particulars may be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD, Tyne and Wear. (939)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR DEPARTMENT OF ZOOLOGY

Applications are invited for the post of **RESEARCH ASSISTANT** (salary range £1,515 to £1,683 per annum, plus threshold payment, plus F.S.S.U.) to work with Dr B. K. Follett on the general problem of the photoperiodic control of seasonal breeding cycles in birds. The post is supported by the Agricultural Research Council and is available from October 1, 1974 for up to five years. It is likely that the person appointed will have a degree in a biological discipline.

Applications (2 copies) stating age, qualifications etc., together with the names and addresses of two referees should be submitted by September 24, 1974, to the Secretary and Registrar, University College of North Wales, Bangor LL57 2DG, from whom further particulars may be obtained. (900)

WEST BERKSHIRE HEALTH DISTRICT MEDICAL PHYSICS TECHNICIAN

for the modern Isotope Laboratory at the Royal Berkshire Hospital, Reading, for interesting work in the chemistry and physics of medical isotope techniques. Post will be on Grade V or Grade IV (£1,308 to £1,667 or £1,530 to £1,953). Day release for further training possible. (Normally O.N.C. or 2 'A' levels required.)

Reading is a pleasant University town offering easy access to London, Oxford, Windsor, Henley and attractive surrounding countryside.

Written applications with relevant details and naming 2 referees to Hospital Secretary, Royal Berkshire Hospital, London Road, Reading. (862)

SUPERVISOR

Vaccine Quality Control

We have a vacancy in our Vaccine Quality Control Department for a Supervisor for our Virus Assay and Tissue Culture Laboratories.

The work involves responsibility for the adequate supply of a variety of tissue cultures for vaccine testing, the assay and serological work associated with polio vaccine manufacture, the preparation of all potency data for submission in protocols to regulatory authorities and the day-to-day supervision of nine weekly paid staff.

Candidates should have a degree in Microbiology or related subject(s) or an equivalent qualification. Several years' working experience in laboratories incorporating basic virological and tissue culture techniques is essential.

Our plant and laboratories are situated in a pleasant location on the Kent coast and we offer the range of fringe benefits to be expected of an expanding international organisation. Considerable assistance towards the cost of moving home can be provided where necessary.

Pfizer

Applicants are asked to write, giving brief relevant details, to:

J. E. T. Haile,
Personnel Department
Pfizer Limited
Sandwich, Kent.

(927)

**ENVIRONMENTAL
CARCINOGENESIS
RESEARCH ASSISTANT**

We need a new member to work in a small group on enzyme induction, its mechanism, and role in cell injury. The main project would be using tissue culture. The suitable person would probably be a biochemistry graduate. Initial appointment up to three years. May be able to register for a Ph.D. Starting salary in the range £1,500 to £2,000 p.a. (Whitley Council scale). Enquiries giving qualifications and any experience to Dr A. McLean, University College Hospital Medical School, University Street, London WC1E 6JJ. (901)

**UNIVERSITY OF BRISTOL
APPOINTMENT OF A LECTURER
IN ANIMAL REPRODUCTION**

Applications are invited for the post of Lecturer in Animal Reproduction within the Department of Animal Husbandry. It is desirable for applicants to have developed teaching skills and recognised research achievements in this field.

The salary will be in the range £2,118 to £4,896 per annum; the starting point will be according to age and experience.

Applications (two copies, please, quoting reference H.G.T.) should be sent to the Secretary, University of Bristol, Senate House, Bristol BS8 1TH, from whom further particulars of the post may be obtained. The closing date for the receipt of applications is Friday, September 20, 1974. (907)

**UNIVERSITY OF EDINBURGH
DEPARTMENT OF ELECTRICAL
ENGINEERING
POSTDOCTORAL RESEARCH
ASSISTANT**

Applications are invited for the post of Research Assistant in the Department of Electrical Engineering. The successful Candidate would join a well-established research group and study dynamic switching processes in amorphous semiconductors under the supervision of Dr J. M. Robertson and Dr A. E. Owen.

The work is funded by the Science Research Council and the post is tenable for 3 years from October 1, 1974. Applicants should normally have a Ph.D. or equivalent industrial experience. The salary will be on the scale £2,412 to £2,757 with F.S.S.U. and threshold payments.

Applications (3 copies) including names and addresses of three referees should be sent as soon as possible to Dr J. M. Robertson, Electrical Engineering Department, King's Buildings, Edinburgh EH9 3JL, from whom further details can be obtained. Please quote reference number 5044. (908)

**UNIVERSITY OF
NEWCASTLE UPON TYNE
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH
ASSOCIATE**

Applications are invited for an M.R.C. supported postdoctoral research associateship for work on DNA repair, replication and genetic recombination in *Escherichia coli*. Experience in enzymology or bacterial genetics would be an advantage.

The appointment is initially for two years with a starting salary of up to £2,412 per annum plus F.S.S.U. Applications including a brief curriculum vitae and the names of two referees should be sent to Dr P. T. Emmerson, Department of Biochemistry, The University of Newcastle upon Tyne NE1 7RU. (921)

**PORTSMOUTH POLYTECHNIC
DEPARTMENT OF BIOLOGICAL SCIENCE
LECTURER
GRADE I or II**

Applications are invited from suitably qualified candidates for a temporary Lectureship in Biochemistry, for an initial period of one year with possibility of extension or permanency. Preference will be given to candidates with research, teaching or industrial experience.

Salary Scales: Lecturer Grade I £1,800 to £3,045 per annum; Lecturer Grade II £2,700 to £3,474 per annum.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by September 16, 1974 (quoting ref. B15). (924)

Veterinary Research Officer—Omagh

£2,917 to £4,505

Applications are invited for a pensionable post in the Department of Agriculture's Veterinary Investigation Laboratory at Omagh, Co. Tyrone, which provides a diagnostic and advisory service for practising veterinary surgeons.

Applicants must have a veterinary degree, and post-graduate experience in a diagnostic laboratory or in veterinary practice is essential.

Duties will involve diagnostic pathology and bacteriology but opportunities will be available to develop particular lines of investigation.

Salary Scales:

Veterinary Research Officer (II) £2,917 to £3,843

Veterinary Research Officer (I) £3,746 to £4,505

Grading and starting salary will be related to qualifications and experience, and a cost of living supplement is payable.

Please write or telephone for an application form and further information, quoting Ref. SB 234/74/N, to the Secretary, Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned to arrive not later than September 24, 1974.

**NORTHERN IRELAND
CIVIL SERVICE**

(925)

GRADUATE CHEMIST

An opportunity exists for a chemist to join a small multidisciplinary team concerned with novel approaches to animal and veterinary infections. The work will be concerned with isolative and synthetic chemistry relating to naturally occurring macromolecules.

It is anticipated that the successful applicant for this vacancy will have a degree in Chemistry and an interest in Biochemistry. He or she will receive appropriate training in the handling of macromolecules.

A good starting salary will be offered and reviewed regularly. Beecham Pharmaceuticals—Research Division is part of Beecham Group, and is situated in a pleasant area of Surrey within easy reach of London.

The successful applicant will qualify for the Group's generous bonus scheme and non-contributory pension and life assurance scheme.

Please send full details to: The Personnel Officer, Beecham Pharmaceuticals—Research Division, Brockham Park, Betchworth, Surrey RH3 7AJ, or ring Betchworth 3202 extension 55 for an application form. (892)

**UNIVERSITY OF GLASGOW
RESEARCH ASSISTANT**

**UNIVERSITY DEPARTMENT OF SURGERY,
GLASGOW ROYAL INFIRMARY
RADIOIMMUNOASSAY UNIT
STOBHILL HOSPITAL, GLASGOW**

Applications are invited for the post of RESEARCH ASSISTANT in an interdisciplinary group investigating the production of foetal antigens by human tumours. The post is suitable for a graduate in biochemistry or related subject. The successful candidate will work initially in the Radioimmunoassay Unit, Stobhill Hospital. The salary will be approximately £1,800 per annum, F.S.S.U. Starting date by agreement. The appointment is tenable for one year in the first instance.

Further information can be obtained from Dr J. G. Ratcliffe, Radioimmunoassay Unit, Stobhill Hospital, Glasgow G21 3UW to whom applications, including curriculum vitae and the names of two referees, should be sent by September 13, 1974.

In reply please quote Ref. No. 3536M. (917)

CSIRO**AUSTRALIA****DIVISION OF PROTEIN CHEMISTRY
PARKVILLE, VIC.****POSTDOCTORAL
FELLOW****POSITION NUMBER 462/397**

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: PROTEIN CHEMISTRY

GENERAL: The Division of Protein Chemistry is located at Parkville, Victoria and has a research staff of some 60 organic and physical chemists, biochemists and biophysicists. Research in the Division deals mainly with the structure and chemistry of the wool fibre and its constituent proteins and comparative studies on related keratins. It also includes studies on leather manufacture and on muscle proteins, seed proteins, enzymes, virus proteins and allergens. There is also a nucleus of work on the biology of hair growth using cell and tissue culture techniques.

DUTIES: To investigate some of the factors controlling hair growth and especially the possible existence of an antimetabolic factor (chalone). The ultimate aim of the work is to facilitate controlled biological (chemical) defleecing of sheep.

QUALIFICATIONS: A Ph.D. in the appropriate field together with demonstrable research ability. Applicants with some experience in histological techniques would be preferred.

**POSTDOCTORAL
FELLOW****POSITION NUMBER 462/396****FIELD: BIOCHEMISTRY**

GENERAL: The Division of Protein Chemistry is located in Parkville, close to Melbourne University, and has a research staff of about sixty scientists. A wide range of physical techniques is available in the Division including an analytical ultracentrifuge, u.v., i.r. and fluorescence spectroscopy; e.s.r., n.m.r. and mass spectrometry. Facilities are also available for the large scale preparation of proteins, for amino acid analysis and sequencing and for gas and other forms of chromatography.

BACKGROUND: During the biosynthesis of keratin fibres such as wool and hair the cell membranes undergo a transformation in the latter stages of development which involves profound structural changes. The transformed membranes exert an important influence on the surface properties of the fibre and also form a barrier to the penetration of various reagents.

DUTIES: To study the nature of the lipid component of the membranes and to investigate the form of the binding between the lipid and protein components. This information could be of great importance in binding macromolecules and other reagents at the fibre surface.

QUALIFICATIONS: A Ph.D. degree, or equivalent qualification, in an appropriate discipline together with a demonstrated ability for original research. Experience in the fields of physical organic chemistry or biochemistry would be advantageous.

SALARY: Appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

TENURE: These positions are available for a fixed term of three years.

APPLICATIONS: Applications stating full personal and professional details, the names of at least two professional referees, and quoting the appropriate Reference Number should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway,
LONDON WC2B 6BD

by the 27th September, 1974.

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(897)

**HARP LAGER BREWERY
(SOUTHERN) LTD****CHEMIST/BIOCHEMIST**

Harp Lager has a vacancy for a young Chemist or Biochemist, preferably between 22 and 27 years of age, to work in the Production Control Laboratory of their Brewery at Alton. The commencing salary will be in the range of £2,250 to £2,600 a year, in addition there is currently a threshold payment.

The work entails responsibility for both non-routine analyses, for which a knowledge of G.L.C. and other instrumental techniques will be necessary, and the supervision of routine Quality Control analyses. Experience in analytical development and/or relevant industrial experience would be an advantage.

Applicants, male or female, should have good graduate or other recognised equivalent qualifications in Chemistry or Biochemistry.

Applications, which will be treated in strict confidence, should include details of qualifications, experience, age and other relevant particulars and be addressed to:

The Administrative Manager,
Harp Lager Brewery (Southern) Ltd.,
Manor Park,
Alton,
Hants. GU34 2PS. (912)

BIOLOGIST WANTED

A Programme Director is wanted to be in charge of the North American Salmon Research Centre at St Andrews, New Brunswick, Canada, and, in particular, of a study of the genetics and selective breeding of Atlantic Salmon. Under a three-way contract the International Atlantic Salmon Foundation is financing the construction of a hatchery and rearing station in which initial multiple crosses of Atlantic salmon stocks are being made in the autumn of 1974. The administration of the programme is by the Huntsman Marine Laboratory, its operational costs by the Canadian Government Fisheries and Marine Service. The scientific planning to date was by an eminent geneticist. Courses in aquaculture technology are planned in association with the salmon genetics programme; provision is planned for ancillary research by scientists from universities or other agencies.

This unique and developing programme is expected to contribute to the improvement of North American Atlantic salmon stocks. To direct it a biologist is wanted with broad interests and experience, especially in genetics, nutrition, disease or other fields related to its objectives. Education should be at a doctoral level. Salary is negotiable in the range \$18,000 to \$24,000. Availability should be not later than May 31, 1975.

Applications, with curriculum vitae, should be sent to Dr A. W. H. Needler, The Huntsman Marine Laboratory, St Andrews, New Brunswick, Canada, and will be accepted to October 1, or until the position is filled. (919)

**WESTFIELD COLLEGE
(University of London)**

Two year Postdoctoral Appointment (Lectureship Scale) to study the fate of P.C.B. pollutants in shallow marine ecosystems. Experience with G.L.C., suspension feeding in bivalves or meiofauna/sediment relationships pertinent but not essential. Apply at once with the names of two referees to Dr W. A. M. Courtney, Department of Zoology N, Westfield College (London University), Kidderpore Avenue, Hampstead NW3 7ST. (896)

**UNIVERSITY OF GLASGOW
POSTDOCTORAL RESEARCH
APPOINTMENT**

Applications are invited from Organic Chemists for a Postdoctoral appointment to carry out research on the chemistry of substances produced by infection of potato tissue with fungal pathogens. The appointment is for three years from October 1, 1974, at an initial salary of £2,247 rising to £2,412 and £2,580 per annum. F.S.S.U.

Further details may be obtained from Dr N. J. McCorkindale, Department of Chemistry or Dr D. D. Clarke, Department of Botany, the University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 3534M. (914)

UNIVERSITY OF LONDON
INSTITUTE OF NEUROLOGY
 (QUEEN SQUARE)
TECHNICIAN

required to do quantitative polyacrylamide electrophoresis of spinal fluid proteins. Initial appointment for one year. Write giving details of previous experience and names of two referees to The Secretary, Institute of Neurology N, Queen Square, London WC1 3BG. Salary on University Scale £1,557 plus £228 London Weighting. (895)

THE MACAULAY INSTITUTE
FOR SOIL RESEARCH

DEPARTMENT OF SPECTROCHEMISTRY

Applications are invited for a physical or inorganic chemist to undertake investigations into the trace element status of soils, plants and other biological materials by spark-source mass spectrometry. The work will involve the development of analytical and diagnostic techniques.

Candidates should possess a First or Upper Second Class Honours Degree in Chemistry, or a Higher Degree, and have an aptitude for experimental research.

The appointment will be in the Scientific Officer (£1,931 to £2,675 per annum) or Higher Scientific Officer (£2,461 to £3,371 per annum) grade, according to qualifications and experience, at least two years relevant post-qualifying experience being required for appointment as H.S.O. Superannuation under F.S.S.U., with a non-pensionable allowance to offset personal contributions.

Forms of application and further particulars may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned before September 13, 1974. (Quote Ref. 74/19). (890)

NATIONAL ORGAN MATCHING
AND DISTRIBUTION SERVICE

A vacancy exists for a computer scientist in the National Organ Matching Service at the Regional Transfusion Centre, Southmead, Bristol BS10 5ND.

The Service makes use of computers in several facets of its work and the appointee will be expected to play a major role in the rationalisation and development of this work. Candidates should therefore have a strong interest in development of information storage and retrieval systems for specialised medical data as well as for scientific analysis. The appointment will be initially for a two year period and will then be subject to review.

Salary scale, Junior Scientific Officer, commencing at £1,497 rising to a maximum of £2,694.

Application forms and further details of the post may be obtained from the Administrative Officer at the above address. (915)

ENTOMOLOGIST

Applications are invited for the post of Editorial Assistant on Entomology Abstracts. Candidates should have a degree in zoology, with specialisation in entomology, or qualification in entomology. Working knowledge of French or other European language an advantage. Starting salary £1,721 p.a. Applications to: Dr E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG.

Applications are invited for the post of Assistant Editor and Editorial Assistant. On Entomology Abstracts, candidates should have a degree in Zoology, with specialisation in Entomology, or qualification in Entomology.

Work knowledge of French or other European language an advantage.

Starting salary £1,912 p.a. and £1,721 p.a. respectively. Applications to Dr E. S. Krudy, Information Retrieval Ltd, 1 Falconberg Court, London W1V 5SG. (916)

UNIVERSITY OF BATH

Applications are invited for the post of

PROFESSOR OF PHYSICS

which falls vacant due to retirement on September 1, 1975.

Further particulars may be obtained from Personnel Officer, The University, Bath BA2 7AY, quoting reference 74/156. Closing date: October 4, 1974. (918)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF BIOCHEMISTRY

Research Associate/Senior Research Associate or Research Fellow is required for an investigation of the mechanism of stimulation of lipid-metabolising enzymes in synaptic membranes of the central nervous system. The post will be supported by a grant from the Medical Research Council for three years. Enquiries and applications to Dr C. E. Rowe, Biochemistry Department, University of Birmingham, P.O. Box 363, Birmingham B15 2TT. (931)

Imperial College

Division of Life Sciences

Electron Microscopy Unit

Vacancy for suitably qualified person to take charge of a new Electron Microscopy unit which will provide a service to staff and students of the division of life sciences.

Duties include sole responsibility for the running and maintenance of the Electron Microscopes in the unit including transmission and scanning, development of additional equipment and techniques and advice and assistance to users of the microscopes.

Salary in the range £3,045—£3,429 plus threshold Superannuation, four weeks leave plus additional days at Christmas and Easter: excellent staff amenities.

Further details from, and applications to: Mr R. Adams, c/o Botany Department, Imperial College, London SW7 2AY by September 30, 1974. (904)

UW Wageningen

LANDBOUWHOGESCHOOL WAGENINGEN
THE NETHERLANDS

Applications are invited for the vacant chair in
PHYSICAL BIOLOGY

Preference will be given to a biologist, more specifically to a botanist with outstanding research experience in either photobiology or physiology of membrane functions, or both.

The appointee will be responsible for the programs in teaching and research of the Department of Physical Biology (formerly known as the Laboratory of Plant Physiological Research).

He will supervise the existing research programs of the department and stimulate new applications of physical methodology to the study of the biology of plants, animals and microorganisms.

He will be expected to contribute proportionally to the teaching obligations of the Landbouwhogeschool, together with the staff of the Department.

Applicants and those who want to make suggestions as to qualified persons, are invited to address to the Cabinet of the Faculty of the Agricultural Sciences, Salverdaplein 11, Wageningen, the Netherlands, within 4 weeks after the insert of this advertisement, supplying detailed information and mentioning the number 74-87 on the envelope. (909)

ST BARTHOLOMEW'S HOSPITAL
WEST SMITHFIELD, LONDON EC1A 7BE
RESEARCH ASSISTANT

Graduate or qualified technician required to join a small research team on the Surgical Professorial Unit investigating the immunosuppressive effect of cancer. Present studies are directed towards the effect of gastrointestinal cancer on human lymphocyte function. Biochemical or immunological background preferred. Opportunity may arise for successful candidate to study for further degree.

Commencing salary (according to qualifications) between approx. £1,750 p.a. and £2,500 p.a.

Applications plus curriculum vitae and two names or reference to Personnel Department (quoting R/4687/N by September 16, 1974. (928)

UNIVERSITY OF LEEDS
RESEARCH TECHNICIAN (Grade 3)

A Research Technician is required to assist experimental studies of the effect of Radiation and Chemotherapeutic agents on mammalian cells. Salary scale: £1,650 to £1,920 plus threshold payments. Applicants should have experience of tissue culture techniques and an interest in work with experimental animals. Applications stating age, qualifications, experience and present salary together with the names of two referees, should be sent to: Professor C. A. Joslin, the University Department of Radiotherapy, Cookridge Hospital, Leeds LS16 6QB, from whom further details may be obtained. (949)

CANADA

Several vacancies exist with the Department of Mineral Resources in Saskatchewan for Geologists II and I Geophysicist. Qualifications required range from a good Honours Degree in Geology to a PhD.

Salary Range from Oct 1st, 1974:—

GEOLOGIST II with Ph.D.
\$15,000 to \$19,128
GEOLOGIST II and GEOPHYSICIST II
\$14,292 to \$18,216
GEOLOGIST I
\$12,492 to \$15,924

Closing date for applications October 1 1974.
Application Forms may be obtained from The Public Service Commission, 1820 Albert Street, Regina, Saskatchewan S4P 2S8 and, details of positions, etc., from D. R. Francis, 2708 12th Avenue, Regina, Saskatchewan, S4S 0B1, Canada.

(893)

THE ROYAL FREE HOSPITAL HAMPSTEAD

E.E.G. TECHNICIAN

(Part-Time)

Half-time E.E.G. Technician or Neuriphiological Technician with E.E.G. experience to work in the Department of Psychological Medicine. Experience of telemetry or computer based techniques would be an advantage, but is not essential.

The appointment will be at the New Royal Free Hospital, Hampstead, following a short initial period at the existing Liverpool Road Branch.
Further information from the Department of Psychological Medicine. Tel: 226 3043 Ext: 147. Application forms (to be returned by September 11) from the Personnel Department, 21 Pond Street, Hampstead NW3 2PN. Tel: 794 0431 Ext: 2. (923)

UNIVERSITY OF RHODESIA CHAIR AND HEADSHIP OF THE DEPARTMENT OF GEOGRAPHY

This post will be vacant from March 1, 1975 and applications for it are invited.

Salary Scale (Approx. Stg. equivs.): £7,557 by £281 to £8,962.

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and biennial visits with travel allowance. Superannuation and medical aid scheme.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth etc), qualifications, experience and publications and giving names and addresses of three referees, should be submitted by **October 7, 1974** to the Registrar, University of Rhodesia, P.O. Box 2702, Salisbury, Rhodesia, from whom further particulars may be obtained. Overseas applicants please send a copy of their applications to Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. (952)

OXFORDSHIRE AREA HEALTH AUTHORITY (TEACHING) ASSISTANT IN IMMUNOPATHOLOGY

Applications are invited from Science Graduates for the post of assistant in Immunopathology. Although it is not essential that applicants should have had previous experience in this field, they should be familiar with general biological laboratory technique. This post offers good opportunities for training in a full range of immunological techniques and participation in research investigations.

It is hoped that the successful applicant will take up the post in September.

The salary scale will be that for Biochemists, Physicists and Scientific Officers in the National Health Service (Probationary Period £1,497 to £2,259. Post probationary period £1,953 to £2,674). The starting point will depend on qualifications and experience.

Applications with details of training and experience should be submitted to Dr M. M. Pickles, Immunopathology Unit, Gibson Laboratories, Radcliffe Infirmary, Oxford from whom further particulars can be obtained.

Closing date September 6. (947)

Imperial College

Department of Biochemistry

An experienced technician is required to work in the field of Nucleic Acid research. The work will involve Purification of Proteins and Nucleic Acids. Radioactive Techniques, high voltage Electrophoresis. Gel Electrophoresis and some Micro-analytical techniques. The successful candidate should have experience in some of these fields.

The appointment is supported by an M.R.C. grant and is tenable for 3 years, commencing on October 1, 1974.

Salary in the range £2,007 to £2,157 plus £228 per annum London Weighting and threshold payments. Applications to Departmental Superintendent, Department of Biochemistry, Imperial College, London SW7 2AY. (905)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE SCIENTIFIC OFFICER

Applications are invited for a post as SCIENTIFIC OFFICER in the Chemistry Division to assist with research in a small group concerned with the chemistry of sulphur compounds in relation to food. Candidates should possess a degree, H.N.C., or equivalent professional qualification in chemistry with an interest, and preferably experience in, the synthesis of organic compounds.

Salary: In the scale £1,592 to £2,675, with starting salary depending upon qualifications and experience. The post is pensionable under a non-contributory superannuation scheme.

Application forms and further particulars from the Secretary, Food Research Institute, Colney Lane, Norwich NOR 70F, quoting Vacancy No: 74/12. (930)

Imperial College DEPARTMENTS OF BIOCHEMISTRY CHEMICAL ENGINEERING

Applications are invited from graduate Microbiologists or Chemical Engineers for the post of research officer for studies concerning Aeration + Agitation Phenomena in Conventional Stirred Fermenters in the presence of Viscous Non-Newtonian Culture Fluids. The Department possesses a comprehensive semi-industrial scale fermentation pilot plant with unique facilities for this type of work. The project is part of a collaborative research programme between the departments of Biochemistry and Chemical Engineering for a 3 year period.

Salary in the range £1,485 to £3,498 plus threshold payments, with F.S.S.U. Applications to be sent to Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AY. (903)

Imperial College

Department of Biochemistry

M.R.C. sponsored postdoctoral research assistant required to work on the structure and recognition of messenger RNAs. Experience in TB field of Nucleic Acid research and/or Prote Synthesis is desirable but not essential. The appointment is tenable for 3 years, commencing on October 1, 1974.

Salary range £2,331 to £2,625, with F.S.S.U. applications including curriculum vitae and the name of two referees should be sent to Dr M. Szekely, Department of Biochemistry, Imperial College, London SW7 2AY.

(906)

AGRICULTURAL RESEARCH COUNCIL SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER

required to join multidisciplinary research team studying new areas in the physiology and biochemistry of growth and development of meat producing animals. An interest in the metabolism of hormones and drugs would be an advantage.

Minimum qualifications: Pass degree, H.N.C. or equivalent (preferably physiology, chemistry, or related subjects).

SALARY: Scientific Officer scale £1,592 to £2,675; Higher Scientific Officer scale £2,461 to £3,371 depending on qualifications and experience, a minimum of 5 years post qualifying experience being required for appointment in the H.S.O. grade. Non-contributory pension scheme.

Application forms (quote ref. BP.39): Secretary, Meat Research Institute, Langford, Bristol BS18 7DY. (963A)

UNIVERSITY OF MALAYA RESEARCH ASSISTANTSHIP FOR I.D.R.C. PROJECT (FOOD FERMENTATION)

Applications are invited from University graduates who are Malaysian citizens for posts in research in food and fermentation microbiology and animal nutrition.

Two scholarships, available for approximately 2½ years, sponsored by the International Development Research Centre for research in methods of solid substrate food fermentation and biological evaluation of the products as enriched animal feedstuffs.

One post requires a candidate with an Honours degree (minimum Second Upper) or equivalent in nutritional biochemistry or animal nutrition with a basic background of biochemistry, bacteriology, and/or food science; the other post requires a candidate with an Honours degree (minimum Second Upper) or equivalent in the field of microbiology with a basic knowledge in biochemistry, bacteriology and/or food science.

This project is at present in progress. The preliminary findings are encouraging and should give the successful candidate a challenging opportunity for original research. This scholarship carries a stipend of M\$700 per mensem for the first 12 months followed by M\$800 per mensem beyond that period.

The successful candidates will be required to enrol for study leading to higher degrees (M.Sc. or Ph.D.) at the University of Malaya.

Applications should be made on prescribed forms (9 copies) and sent to the Registrar (Recruitment Section), University of Malaya, Kuala Lumpur 22-11, Malaysia, together with a copy of transcript of the academic record of the candidate. Application forms and further information about the positions, including conditions of appointment, may be obtained from the above address. Closing date for applications is **October 26, 1974**. The University does not pay travelling or any other expense to candidates to attend interviews. Eligible candidates who may be overseas at the time of advertisement may be exempted for interview subject to the location and qualification of the applicants. Ref: UM.1118 Pt. XI (237). (953)

IIRS
IRELAND

DIRECTOR OF SCIENCE DIVISION

The Institute for Industrial Research and Standards is an agent of the Irish Government charged with the responsibility for assisting in the industrial development of the country by providing technological support to industry.

The post of Director of the Science Division is a challenging post in the senior management of the Institute. The Division has 140 staff in Departments of Chemistry, Physics, Food Technology, Forest Products and Chemical Engineering which provide a wide range of services to various sectors of industry. Among the activities of the Division are services in air and water pollution abatement, minerals and inorganic materials technology, chemical analysis and computing. The types of services range through testing, field advisory work, technical consultancy and applied research and development. The Director will ensure that the services are responsive to the needs of industry. He will maximise the effectiveness of all services and the income earned for them from industry. He will be responsible in particular for the management of both contract and Institute-sponsored applied research and development programmes/projects and his effectiveness in this context will be measured against the criterion of commercial success.

The successful candidate will be a scientist of high academic attainment with proven management ability and at least ten years' experience in industry, much of which should have been in applied research and development. The salary is in a range rising to a maximum of £6,600.

Further particulars concerning the post and application forms are available from:

**THE PERSONNEL MANAGER,
INSTITUTE FOR INDUSTRIAL RESEARCH AND
STANDARDS,
BALLYMUN ROAD, DUBLIN 9, IRELAND,
who should receive completed forms not later
than September 30, 1974.**

(910)

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS. AL5 2JQ HIGHER SCIENTIFIC OFFICER/ SENIOR SCIENTIFIC OFFICER

required for a two-year appointment as a BIOLOGIST to work in the Nematology Department on nematodes of arable crops. Good honours degree in Botany, Zoology or other branch of Biology required. At least two years' postgraduate experience for appointment as H.S.O., and four years as S.S.O. Experience in Plant Nematology is essential for appointment as S.S.O.

Starting salary according to qualifications and experience:

H.S.O.: £2,461 to £3,371.
S.S.O.: £3,157 to £4,441.

plus threshold payments. Superannuation with a contribution of 1½% for family benefits (male staff).

Applications giving full personal details, naming two referees and quoting Reference No. 2382 to The Secretary ●, September 21, 1974. (950)

SENIOR TECHNICIAN DRUG METABOLISM

An experienced Technician is required to work in the Drug Metabolism Section of Boots Research Department, whose modern well-equipped laboratories are situated in Nottingham.

The successful candidate will have H.N.C. or H.N.D. or an equivalent qualification, and will be concerned primarily with in vitro techniques used in the study of drug metabolism.

Experience in tissue fractionation, enzymology and the use of radioactive materials would be an advantage.

The conditions of employment are good, including a profit earning bonus and contributory pension schemes.

Please write, giving brief details of age, qualifications and experience to: Mrs E. M. Durrance, Employment Services, The Boots Company Limited, Station Street, Nottingham NG2 3AA. (948)

CSIRO

AUSTRALIAN NUMERICAL METEOROLOGY RESEARCH CENTRE

MELBOURNE, VICTORIA

OFFICER-IN-CHARGE

Applications are invited for the position of Officer-in-Charge.

GENERAL: The Centre is a combined activity of the Department of Science and the Commonwealth Scientific and Industrial Research Organisation and is located within the Bureau of Meteorology premises in Melbourne. The main objective of the Centre is to conduct research into numerical methods for improving the accuracy and timescale of weather forecasting and for understanding the global climate and its variations. It includes the interpretation and use of new forms of observational data. The Centre will effectively continue the work of the Commonwealth Meteorology Research Centre which has been in existence for five years. During this period the CMRC has worked on schemes of numerical analysis for the Australian region and the southern hemisphere and on prognosis models of two types, grid-point and spectral, which are respectively in, and close to, operational use. General circulation models are currently being used to investigate relevant climatic mechanisms.

DUTIES: The Officer-in-Charge will be appointed by CSIRO after consultation with the Secretary, Department of Science, and will be responsible for the direction of the scientific programme of the Centre and its administrative control. The Officer-in-Charge will be supported by about ten professional meteorologists from the Bureau of Meteorology, about ten research scientists from CSIRO, together with appropriate computer, programmer, administrative, and clerical support.

SALARY: Appointment will be made within the salary ranges of Senior Principal Research Scientist or Chief Research Scientist Grade 1: \$A19,319 to \$A21,295.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications should state full personal and professional particulars and the names of at least three professional referees, and should reach:—

The Chairman,
Environmental Physics Research Laboratories,
P.O. Box 77, MORDIALLOC,
VICTORIA, AUSTRALIA, 3196

by September 28, 1974

They should include a full statement of the applicant's experience and achievements in numerical meteorology or closely cognate fields, and his views on present prospects and new orientations within the broad objective of the Centre. Intending applicants may obtain a copy of the formal agreement between the Department of Science and CSIRO, under which the Centre will operate, and other relevant material by writing to the above address. (957)

THE UNIVERSITY OF THE WEST INDIES—TRINIDAD EXECUTIVE DIRECTOR

PROPOSED CARIBBEAN AGRICULTURAL RESEARCH AND DEVELOPMENT INSTITUTE

Applications are invited for the post of Executive Director of the Caribbean Agricultural Research and Development Institute (C.A.R.D.I.) which is to be established by the member Governments of the Caribbean Community as the successor organisation to the Regional Research Centre of the Faculty of Agriculture of the University of the West Indies. The Institute has been established to serve the research and development needs of the region and will have its headquarters at the St Augustine, Trinidad, campus of the University of the West Indies.

Applicants should possess a good degree in agriculture or one of its related fields. A higher degree, though not essential, would be a distinct advantage.

The person appointed will have had considerable experience in tropical agriculture or agricultural research and development and/or be an administrator of exceptionally high calibre. Experience with the region would be an advantage.

The Executive Director will be responsible for the day to day control, management and administration of the Institute.

The appointment will be on contract for five years in the first instance. Salary will be negotiable based on qualifications and experience. Other allowances are payable. A gratuity in lieu of pension will be paid. Unfurnished accommodation will be provided at a cost of 10% of salary. Alternatively a housing allowance of 20% salary will be paid in lieu of accommodation. Four weeks annual leave will be granted. Up to five full passages will be provided on appointment and on normal termination.

The person appointed would be expected to assume duties as soon as possible and preferably by October, 1974.

Applications giving full details of date of birth, marital status, qualifications and experience and the names and addresses of three referees should be sent by airmail by September 13, 1974 to the Secretary, University of the West Indies, St Augustine, Trinidad, from whom further particulars can be obtained. (961)

ROYAL POSTGRADUATE MEDICAL SCHOOL

TECHNICIAN (Organic Chemist)

required in the peptide chemistry section of the Endocrine Unit, to assist with the synthesis of biologically active peptides. Qualifications: Relevant 'A' Levels, O.N.C. or H.N.C. in chemistry. Starting salary and grade according to qualifications and experience.

Applications to the Secretary, R.P.M.S., Hammersmith Hospital, Du Cane Road, London W12 0HS, quoting ref. no. 2/322N. (926)

THE UNIVERSITY OF ADELAIDE

invites applications for appointment as

LECTURER IN ANATOMY AND HISTOLOGY

A medical qualification registrable in South Australia is desirable but not essential. The appointment will be made as soon as the person concerned is able to assume duty.

The Department of Anatomy and Histology teaches University students of Medicine, Dentistry and Science, and in addition Physiotherapy and Occupational Therapy students of the South Australian Institute of Technology. Research fields are neuroendocrinology, human and comparative neurology, cell biology, experimental embryology, and clinical anatomy. Persons with an interest in clinical anatomy or gross anatomy are especially invited to apply.

Salary Scale: \$A9,002 by \$A479(4) by \$A478(3) to \$A12,352 (plus a loading for registrable medical qualifications at the rate of \$A833 a year) with superannuation provision.

Further Information, including list of particulars required in an application, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia 5001, not later than September 16, 1974. (929)

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

SENIOR LECTURER/LECTURER IN PLANT TAXONOMY

Applications are invited for appointment to the above post in the Department of Botany and Microbiology. Duties are to be assumed on January 1, 1975 or as soon as possible thereafter.

Reference will be given to those interested in modern systematics (chemosystematics, numerical systematics or experimental biosystematics), but with a training in classical taxonomy.

Salary will be in the following ranges:

Senior Lecturer R7,245 to R9,315.
Lecturer R5,520 to R7,935

The initial salary to be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than September 27, 1974. U.K. applicants may obtain the information sheet from the London Representative, University of the Witwatersrand, 278 High Holborn, London, W.C.1 to whom a copy of the application should be sent. (945)

ROYAL HOLLOWAY COLLEGE (University of London)

EGHAM HILL, EGHAM, SURREY LECTURER IN ZOOLOGY

Lecturer required in the field of Invertebrate Zoology from January 1, 1975. Entomology is the preferred specialty but other fields of terrestrial Invertebrate Zoology are not excluded. Interest in quantitative biology an advantage. Salary up to £2412 plus F.S.S.U. Further details from the Personnel Officer (N). Applications (6 copies please) including a curriculum vitae and the names and addresses of 2 referees should reach her by September 16, 1974. (944)

**LA TROBE UNIVERSITY
MELBOURNE, AUSTRALIA
LECTURESHIP/SENIOR
LECTURESHIP IN
MICROBIOLOGY
(ONE OR TWO POSITIONS)**

Candidates should have experience in any field of microbiology, but there is a need for an appointment in virology. Preference will be given to applicants who have research and teaching experience.

The Department of Microbiology is a new department in the School of Biological Sciences and will offer a widely-based course in general microbiology leading to B.Sc. ordinary and honours degrees. Teaching will commence in March 1975 with an introductory course in microbiology given to second-year science students. Informal enquiries about the proposed development of the department can be sent to the Chairman of the Department, Professor J. S. Waid, whose address until the closing date is Department of Botany, University of Canterbury, Christchurch, New Zealand.

Salary: Senior Lecturer \$A12,643(1) by \$A417(4) by \$A416 to \$A14,724; Lecturer \$A9,002(4) by \$A479(3) by \$478 to \$A12,352.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia 3083.

Applications close on **October 14, 1974.** (943)

RESEARCH TECHNICIAN (Grade 4)

required by Department of Anatomy. To assist in Research Studies on Brain Structure and Central Nervous System. Experience in Electron Microscopy or Neurohistological techniques essential. H.N.C. or equivalent qualification. Salary within scale £1,848 to £2,163 plus £228 London Weighting plus Threshold. Application form from Personnel Officer, (Technical Staff FB24), University College London, Gower Street, London WC1E 6BT. (942)

**University of New South Wales
WOLLONGONG UNIVERSITY
COLLEGE**

TO BECOME THE

**UNIVERSITY OF WOLLONGONG
JANUARY 1, 1975**

LECTURER IN BIOLOGY

Flexibility in the initial academic structure of the Department of Biology will enable applications to be considered from persons competent in the area of Energy Metabolism. The appointee would share responsibility for an instructional unit in Energy Metabolism and in the development of the Biology course as a whole.

Further information may be obtained from The Professor Elect, Assoc. Professor A. D. Brown, School of Microbiology, University of N.S.W., P.O. Box 1, Kensington, N.S.W. 2033, Australia.

Commencing salary according to qualifications and experience, within the range \$A9,002 to \$A12,352.

Applications close **October 4, 1974.**

Conditions of appointment and application procedure from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (962)

**UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF PHYSICS
RESEARCH ASSOCIATE**

Applications are invited for a Research Associate-ship in the Applied Nuclear Science Group to undertake a theoretical investigation of the behaviour of neutrons in the breeder blankets of controlled thermo nuclear reactors. A higher degree and/or experience in neutron physics and computing are desirable.

This three-year U.K.A.E.A. supported programme carries a salary on the Research Associate scale:

£1,758 to £2,412 (exceptionally £2,931) plus F.S.S.U. and threshold payments. Initial placing according to age and experience.

Applications (3 copies), naming 3 referees, should be submitted to the Assistant Registrar(S) P.O. Box 363 Birmingham B15 2TT by September 27, 1974. Please quote ref. NP4. (963)

INFORMATION SCIENTIST

Central Research is the organisation responsible for all research in Pfizer. At Sandwich, Kent, over 450 staff are engaged in research and development of compounds for use in human medicinal and veterinary fields.

We now require to increase the staff in our Research Information Services department by appointing a young graduate. Ideally the man or woman we need will have two or three years' experience in information work and the possession of an M.Sc. (Information Science), postgraduate Diploma in Information Science, or an equivalent qualification would be an added advantage.

The person appointed will be involved in the development and maintenance of information resources, including the exploitation of computer-based information systems. He/she will work in very close collaboration with research project teams. Our conditions of employment include flexible working hours, assistance with relocation expenses where appropriate and free pension and death benefit schemes.

Pfizer

Applications, giving brief details of age and experience, should be addressed to:

**D. W. Sells,
Personnel Manager,
Central Research,
Pfizer Limited,
Sandwich, Kent.**

(959)

Wellcome

Entomologist

The Wellcome Foundation Limited, requires an Entomologist at their Research Laboratories at Berkhamsted Hill, preferably having postgraduate experience in economic entomology and in the biological testing of insecticides. Requirements include an ability to work in a team and to develop initiative in applying knowledge to laboratory and field practice in the U.K. and overseas.

We offer excellent conditions of employment, including help with re-location expenses where necessary, and real career prospects. Our laboratories are modern and well equipped, situated in pleasant countryside close to Berkhamsted, which is a small country town about 35 minutes from Euston, London.

If you are interested please write or telephone for an application form quoting reference PA 62 to:

**R. P. Woolridge, Senior Personnel Officer,
The Wellcome Foundation Limited,
Ravens Lane, Berkhamsted, Herts HP4 2DY.
Tel: Berkhamsted 3333.**

(955)

**THE NATIONAL RADIOLOGICAL
PROTECTION BOARD**
ARE SEEKING A
SCIENTIST
FOR
BIOLOGY DEPARTMENT
OF THE
RESEARCH AND DEVELOPMENT DIVISION

The successful applicant will assist senior scientists in the solution of a wide variety of problems in theoretical dosimetry and epidemiology.

The work currently being undertaken includes the interpretation of biological experiments, the calculation of doses from internally incorporated radionuclides, the assessment of doses received from occupational exposure, and the interpretation of epidemiological data. Good computer facilities are available.

Candidates should possess a first or upper second class degree in mathematics, physics or a biological science coupled with experience in computation.

Salary on the scale £1,705 to £2,865 per annum.

Write or telephone for further information and an application form to:

The Personnel Officer (Ref. A.57),
National Radiological Protection Board,
Harwell,
Didcot,
Oxfordshire OX11 0RQ.

Telephone: Rowstock (023-583) 600 Extn. 216.

Closing date for applications October 4, 1974.

(960)

UNIVERSITY OF DUNDEE
**DEPARTMENT OF PHARMACOLOGY
AND THERAPEUTICS**
RESEARCH STUDENTSHIP

Applications are invited for one M.R.C. studentship for training in research methods. The studentship, which is tenable for up to three years, can be taken up on October 1 1974 or as soon as possible thereafter. The training programme involves studies of the effect of drugs on cerebral histamine metabolism. The Department, which is located in the new Ninewells Hospital and Medical School, is fully equipped for these studies. The successful applicant may register for a higher degree and will receive a stipend in accordance with the rates for M.R.C. students.

Applicants, who should have a first or upper second class honours degree or equivalent in pharmacy, pharmacology, biochemistry or related subject, should write to Professor J. Crooks, Department of Pharmacology and Therapeutics, Ninewells Hospital, Dundee, DD2 1UD, giving their qualifications and the names of two referees. The closing date for applications is September 14, 1974.

(935)

LIVERPOOL POLYTECHNIC
SCHOOL OF PHARMACY
**S.R.C. STUDENTSHIP IN
MECHANICAL CHEMISTRY**

Applications are invited from candidates with a good honours degree in Pharmacy or Chemistry, or Grad. R.I.C., to work for a Ph.D. degree on the project "4-phenylpiperidine derivatives as potential non-addicting analgesics". The work will involve organic synthesis and stereochemical studies. The project is a C.A.S.E. award and the co-operating body is Allen and Hanburys Ltd., usual S.R.C. stipend applies which may be supplemented by payment for teaching duties and income during the industrial period.

Enquiries to: A. F. Casey, D.Sc., F.P.S. School of Pharmacy, Byrom Street L3 3AF. (889)

UNIVERSITY OF NOTTINGHAM
**DEPARTMENT OF AGRICULTURE
AND HORTICULTURE**

The National Environment Research Council is prepared this year to offer to a suitable candidate a Studentship tenable at the University of Nottingham School of Agriculture. The value of the N.E.R.C. awards in 1974 will normally be £880 per annum.

Candidates should have first or upper second class honours degrees. The field of research will be Seed Production of Amenity Grasses.

Applications, marked 'Agriculture' and giving the names and addresses of two referees, should be sent to the Secretary, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough LE12 5RD within two weeks of the appearance of this advertisement. (940)

**ST. MARY'S HOSPITAL
MEDICAL SCHOOL**

(University of London)

PADDINGTON, LONDON W2 1PG

Applications are invited from candidates with an Honours Degree in Chemistry, Biochemistry, Pharmacology or related discipline wishing to work for a Ph.D. degree, for a studentship to work on the metabolic fate of artificial sweetening agents. Apply, with curriculum vitae and names of two referees to Professor R. T. Williams, Department of Biochemistry. (898)

UNIVERSITY OF HULL
DEPARTMENT OF PLANT BIOLOGY

Applications are invited for the post of Post-doctoral Fellow in Plant Biochemistry, to work with Dr D. R. Threlfall on the biosynthesis of isoprenoid quinones and chromanols.

The post is financed by the S.R.C. and is tenable for one year from October 1, 1974, or as soon as possible thereafter.

Salary (excluding threshold payments) will be on the scale £2,226 by £114 to £2,340 by £72 to £2,412, plus F.S.S.U. benefits.

Applications (three copies) giving details of age, qualifications and experience together with the names of two referees should be sent by September 16, 1974 to the Registrar, The University of Hull HU6 7RX from whom further particulars may be obtained. (922)

UNIVERSITY OF CAPE TOWN
SENIOR LECTURESHIP IN ENVIRONMENTAL STUDIES

Applications are invited for the newly created post of Senior Lecturer in Environmental Studies. Appointment, according to qualifications and experience, will be made on the salary scale R6,300 by R300 to R8,100 per annum plus a pensionable allowance of 15% of basic salary. This salary scale does not include improvements under consideration.

Applicants for the post must have interest and experience in at least one aspect of environmental study, should desire to participate in inter-disciplinary teaching and research, and should have a Ph.D. or its equivalent.

Applicants should submit a curriculum vitae, stating present salary, research interests and publications, when available if appointed, and the names and addresses of three suitable referees.

Further information concerning the post and general conditions of service should be obtained from the Registrar, University of Cape Town, Private Bag, Rondebosch, 7700, South Africa, by whom applications must be received not later than November 1, 1974.

Appointment will be subject to a satisfactory medical examination. The University reserves the right to appoint a person other than one of the applicants or to make no appointment. (932)

**THE QUEEN'S UNIVERSITY
OF BELFAST**
**FACULTY OF AGRICULTURE AND
FOOD SCIENCE**
**RICHARDSONS ULSTER
STUDENTSHIP**
**PLANT NUTRITION/PLANT
BIOCHEMISTRY**

Applications are invited for the above studentship from graduates in Science or Agriculture. Preference will be given to applicants of Northern Ireland parentage. The holder will undertake research work into biochemical aspects of plant growth and nutrition and will be required to register for a higher degree of the University. The Department of Agricultural and Food Chemistry is housed in new, well-equipped laboratories on the southern outskirts of Belfast.

The studentship is tenable up to three years and its value will be £750 in the first year and £800 in the final two years. An allowance of £250 to £300 per annum will be available for approved expenses.

Candidates should apply in writing, including a curriculum vitae, to the Dean of the Faculty of Agriculture and Food Science, Queen's University, Newforge Lane, Belfast BT9 5PX. (913)

Imperial College Postgraduate Studentship and Postdoctoral Assistantship in Cancer Chemistry

Applications are invited for a Postgraduate Studentship and a Doctoral Assistantship for a new project sponsored by the Ministry of Agriculture. The work concerns Physical and Organic Chemical aspects of the Interaction of Nitrites and Nitrates with Foodstuffs, particularly in the Digestive Tract.

The postgraduate studentship provides equivalent remuneration to an S.R.C. award (£695 per annum—at present under review), although students who are normally ineligible for an S.R.C. or M.R.C. grant will be considered. The candidate is expected to register for a higher degree.

The postdoctoral assistantship (Salary £2,118 per annum and £213 per annum London Allowance (under review) plus F.S.S.U.) is tenable for up to three years with the usual salary increments. Threshold payments at the authorised rate apply to this post.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to: Dr B. C. Challis, Department of Chemistry, Imperial College, London SW7 2AY. (902)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES PROFESSORIAL FELLOWSHIP DEPARTMENT OF NEUROBIOLOGY

The Department (Head: Professor G. A. Horridge) has an active programme of research in the neural basis of behaviour and perception in lower animals, mainly insects and crustacea. Applicants should be capable of a strong research programme in an aspect of neurobiology which is either complementary or supplementary to the present interests, which include: (a) mechanisms of arthropod vision; (b) growth and regeneration of insect nerves; (c) control of movement in crustaceans; (d) biochemistry of insect neurons; (e) insect sound production and hearing; (f) establishment of connections between nerve cells.

The University is looking for a man with an ambitious project who finds himself restricted by lack of assistance, research time or equipment. Vertebrate neurobiology is not excluded. The position is tenured, with opportunity to train graduate students.

Closing date: September 21, 1974.

Salary: Salary for a Professorial Fellow is \$A18,131 p.a. Current exchange rates are approximately \$A1: 67np; \$US1:49.

Other Condition: Tenure: Professorial Fellow to retiring age (65 years).

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should apply to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (899)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointment:

SENIOR TEACHING FELLOW IN PHYSICAL AND INORGANIC CHEMISTRY

The Senior Teaching Fellow, who should have completed a Ph.D. degree, will devote about half his time to teaching and the other half to research. He will be responsible for the supervising arrangements for some undergraduate practical courses and will initiate new course developments; he will be encouraged to undertake research with one of the existing research groups in the Department, which has good modern facilities. A document detailing research interests within the Department and describing undergraduate class arrangements is available on request (September 13, 1974).

Salary Scale: Senior Teaching Fellow \$A7,545 by \$A292(2) by \$A291(3) to \$A9,002, with superannuation provision.

Further particulars about this post and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, The University of Adelaide, North Terrace, Adelaide, South Australia, 5001. (894)

THE POLYTECHNIC OF CENTRAL LONDON SCHOOL OF ENGINEERING AND SCIENCE BIO-ORGANIC RESEARCH GROUP

RESEARCH FELLOW

£2,151 to £2,331

Applications are invited immediately for the above post which is sponsored by EURATOM for work on mutation in *Aspergillus nidulans* and its relationship in microdosimetric studies. Candidates should have or expect to obtain a Ph.D. in Genetics or Radiobiology.

Application including a curriculum vitae and the names of two academic referees should be sent to The Establishment Officer, PCL, 309 Regent Street, London W1R 8AL. 01-580 2020 Ext 212. (956)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY S.R.C./C.A.S.E. RESEARCH STUDENTSHIP

Applications are invited from graduates with a first or upper second class Honours degree in Botany, Biochemistry or other relevant subject for one S.R.C./C.A.S.E. Research Studentship, tenable from October 1, 1974.

The research topic concerns the use of isoenzyme analysis in assessing the purity of commercially important *Brassica* seeds.

Applications, together with details of academic background and names of two referees should be received not later than September 20, 1974, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. R/V/N/276195. (946)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited from graduates who hold Honours Degrees in Chemistry, Biochemistry, Biology or related subjects at the First or Upper Second Level, and from those who hope to have such qualifications by October 1974, for a C.A.S.E. Studentship concerned with research into sterol ester metabolism in mammalian skin. This will be carried out mainly at the University of Nottingham and in part at the Environmental Safety Division, Unilever Research Laboratory, Colworth House, Bedford, and should lead to a higher Degree.

Research will entail a study of sterol ester metabolism in relation to other lipids in skin, with particular emphasis on prostaglandins, and will also involve fractionation of mammalian skin into its constituent components and cell types, subcellular fractionation of skin, and the effect of environmental change upon sterol ester metabolism in skin.

Further details and application forms may be obtained from Professor J. N. Hawthorne, Department of Biochemistry, The Medical School, The University of Nottingham, Nottingham NG7 2RD. (920)

UNIVERSITY OF MANCHESTER, MEDICAL SCHOOL

RESEARCH ASSOCIATE/ FELLOW

for two years to join team working on immunological changes in connective tissue disease and immune deficiency. The work will be concerned either with variations in lymphocyte function and the effect of treatment, including immunotherapy on this, or with the part played by immunoglobulins in inflammatory joint disease.

Excellent facilities in a newly established and equipped laboratory. Salary on usual scales according to age and experience.

Enquiries to: Dr L. Holt, Medical School, Stopford Building, Oxford Road, Manchester 13. (954)

QUEEN ELIZABETH COLLEGE (University of London)

CAMPDEN HILL ROAD W8 7AH CHEMISTRY DEPARTMENT

Applications are invited for an S.R.C. C.A.S.E. Studentship for research into the physical properties of natural gas mixtures. There will be close collaboration with the London Research Station of the British Gas Corporation.

Further details may be obtained from Dr M. Rigby. (951)

NEW ZEALAND UNIVERSITY OF CANTERBURY CHRISTCHURCH UNIVERSITY POSTDOCTORAL FELLOWSHIP IN CIVIL ENGINEERING

Applications are invited for the abovementioned Fellowship. Applicants should possess a Ph.D. or equivalent degree, preferably followed by some research experience.

Fields within which the Fellowship may be held are: Fluid Mechanics; Highway Engineering; Materials; Photogrammetry; Soil Mechanics; Structural Mechanics; Systems Engineering and Planning.

The emolument is NZ\$6,600 per annum. The Fellowship will be tenable normally for one year, but with the possibility of extension.

Further particulars, and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on October 31, 1974. (941)

UNIVERSITY OF DUNDEE

DEPARTMENT OF MEDICAL BIOPHYSICS

Research in Radiation Damage

Applications are invited from recent honours graduates (preferably in Physics or Physical Chemistry) for a RESEARCH STUDENTSHIP leading to Ph.D. The project envisaged concerns experimental and theoretical studies of energy deposition by heavy charged particles in solid, liquid and gaseous tissue-like media and will form an important part of the general departmental studies into radiation damage by neutrons. Interested individuals should apply, as soon as possible, giving the names of two referees, to Professor J. H. Martin, Department of Medical Biophysics, The University, Dundee DD1 4HN, from whom further details can be obtained.

(958)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL FELLOWSHIP

A Research Fellow with experience in protein and nucleic acid metabolism is required for a three-year project on the post-transcriptional control of protein synthesis in eukaryotic cells.

Salary in the range of £2,118 to £2,412 plus F.S.S.U. and threshold payment.

Enquiries and applications with the names of two referees to Dr H. G. Klemperer, Department of Biochemistry, University of Birmingham, Birmingham B15 2TT.

(891)

LECTURES AND COURSES

THE CITY UNIVERSITY

DEPARTMENT OF CHEMISTRY

LECTURE COURSE ON DUST EXPLOSIONS

A course of lectures of postgraduate status, arranged by Professor J. H. Burgoyne and dealing with the theory and practice of dust explosions and methods of protection against them, will be given from November 4-6, 1974.

Further details may be obtained from The Secretary of the Chemistry Department, The City University, St John Street, London EC1V 4PB.

SUBSCRIPTION – REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

CHARLES C THOMAS • PUBLISHER

ECOPHYSICS: The Application of Physics to Ecology by James Paul Wesley, *Univ. of Missouri, Rolla*. This book contains original research on selected problems in ecological physics. The field of ecology is assumed here to cover a broad range of topics, particularly, any area of research dealing with life as it naturally occurs and which does not involve any detailed internal examination of individual organisms. The book presents a brief review of thermodynamics and considers the strategy of how to optimize the utilization of a source of energy realistically at a finite rate. The author defines life physically, thereby permitting an analysis of the thermodynamic role of life in the ecosphere, and surveys all possible sources of energy since life needs to degrade high utility energy to low utility energy to survive. He explores the stability of the carbon cycle in the ecosphere yielding damped periodic oscillations following any perturbation. He discusses the territorial origin of human conflict and defines motivation in terms of normal ecological roles as predicted by a theoretical structure based upon the energy needs of the individual. The application of the rigorous concepts of physics to ecology has entailed the introduction of certain special definitions and basic new ideas which are presented here for the first time. Written primarily for physicists and mathematicians interested in theoretical ecology, this text should also interest ecologists, biologists, environmentalists and exobiologists with some background in mathematics and physics. '74, 368 pp., 39 il., 8 tables, cloth-\$19.75, paper-\$13.75

HUMAN AND ECOLOGIC EFFECTS OF NUCLEAR POWER PLANTS. Edited by Leonard A. Sagan, *Palo Alto Medical Clinic, Palo Alto, California*. Introduction by Rolf Eliassen. (15 Contributors) There is a widespread need and public desire to better understand nuclear power and its consequences. Reactor technology and its ecologic effects often exceed the detailed understanding of many experts. Compounding this difficulty, the interested layman is also faced with inaccessible and fragmented literature. Although the book is directed toward an exposition of human and ecologic effects, the first section details reactor design and engineering. Such material is necessarily included since many readers will be unfamiliar with reactor design and should have available some understanding of reactors, their operation and methods of generating and releasing radioactivity. Public attention has been focused on nuclear power because of the concern for the environment which has suffered from past and present technology. Contamination of air and water with reactor-produced radioactivity has aroused fears of radiation hazards to both persons and the environment. The mood of the public has generated the desire for wider participation in decision making and the loss of faith in those institutions to which these decisions have traditionally been delegated. This book is meant to serve both as a comprehensive introduction for the interested layman and as a useful reference for the technical expert. '74, 560 pp. (7 x 10), 138 il., 86 tables, \$34.50

THE BIG BANG IS A BUST

Physicists generally agree that one should not postulate a force in order to explain a phenomenon that would occur even without such a force. One of our physicists has now shown that the big bang theory is a case in point. Writing in *Foundations of Physics*, A. D. Allen demonstrates that the uniform velocity of galaxies in unbounded space will cause the cosmos to evolve naturally into an expanding universe. If you want to get a bang out of cosmology, drop us a line and we'll send you a copy of Allen's paper.

Genetic Control of Insect Pests

G. Davidson

August 1974, x+158 pp., £4.00/\$10.25 0.12.200850.2

This is the first book to consider, together, all the genetic methods for controlling insect pests agricultural, veterinary and medical importance, which have so far been developed to the point of practical application. As such it will be of the greatest interest to entomologists working in these fields, to doctors, concerned with preventive medicine and to biologists and those with more general interest in entomology and genetics.

contents

Introduction. The principles and dynamics involved in the sterile insect technique. Sterilization by irradiation. Chemosterilants. Hybrid sterility. Cytoplasmic incompatibility. Translocations. Other methods of genetic control. Summary and conclusion. References. Subject index.

British Acoustical Society Special Volume No. 2

The Vibration Syndrome

Proceedings of a Conference on the Medical, Engineering and Legal Aspects of Hand-Arm Vibration, at the University of Dundee, July 1972

edited by W. Taylor

August 1974, xii+226 pp., £6.00/\$15.50 0.12.684760.6

The Vibration Syndrome contains papers, given at a conference at the University of Dundee, in 1972, which present recent clinical and vibration studies, related mainly to the prolonged use of hand-held vibratory tools. This conference was inter-disciplinary and involved physicists and engineers as well as members of the medical and legal professions.

One of the main aims of the conference was to correlate the physical parameters of the vibration with the resulting VWF. From this data it was hoped to develop a Vibration Standard which would limit the damaging effects of hand-held vibratory tools in the future.

Introduction to Particle Production in Hadron Physics

S. Humble

August 1974, viii+254 pp., £6.80/\$17.50 0.12.361450.3

This volume introduces the important and rapidly growing field of particle production physics ranging from low energy single particle production to high energy many particle reactions. The work, which will function jointly as an introductory text, reference guide and critical review of recent advances, is the first in a popular subject, as yet not adequately covered by other books. Its value will be appreciated by graduate students and research workers in theoretical and experimental physics, and also applied mathematicians and high energy physicists.

The Structure of Mitochondria

E. A. Munn

August 1974, xiv+466 pp., £9.80/\$25.50 0.12.510150.3

The aim of this book is to provide a general survey of the structure of mitochondria from the level of resolution achieved by light microscopists down to the 2.45Å, achieved by X-ray crystallographers. The greatest emphasis, however, is placed on the results of electron microscopy and on the correlation of the results of the structural studies made while using biochemical and biophysical techniques.

This is the first book to deal with a topic which, because of the fundamental importance of mitochondria, is of enormous interest to biologists and yet has not been reviewed in its entirety for three years.

A NATO Advanced Study Institute

Phenomenology of Particles at High Energies

Proceedings of the Fourteenth Session of the Scottish Universities Summer School in Physics edited by R. L. Crawford and R. Jennings

August 1974, xii+744 pp., £18.20/\$47.25 0.12.197150.3

This volume presents the latest trends in high energy physics in a didactic fashion. The subject of the School was the phenomenology of particles at high energies: this was chosen as being particularly timely in view of the new and exciting data flowing from the CERN Intersecting Storage Rings and NAL (Batavia, USA), and in view of the very considerable developments in phenomenological theory for high energy processes. The papers were given by innovators in the field and contain new material, as well as reviews of recent developments often difficult to gather from the literature.
